The Commission considers program proposals such as the Customer Programs, to be a normal part of DEP's operations to provide benefits to customers with respect to billing and payment options and other customer service offerings pertaining to the provision of electric utility service. With respect to PIMs, the Commission acknowledges that this is the first time the Commission is considering PIMs in a general rate case proceeding; however, PIMs are now statutorily part of the normal course of business when a utility elects in its discretion to pursue an MYRP. Accordingly, DEP's request to defer these costs is denied. To the extent that there are ongoing O&M expenses associated with implementation of the PIMs and customer programs, DEP may seek cost recovery of actual expenses incurred during a future test period in its next general rate case.

EVIDENCE AND CONCLUSIONS FOR FINDING OF FACT NO. 70

Interconnection CIAC Regulatory Liability Recommendation

The evidence supporting this finding of fact is contained in DEP's verified Application and Form E-1; the Revenue Requirement Stipulation; the testimony and exhibits of DEP witness Speros and Public Staff witnesses Zhang and Boswell; and the entire record in this proceeding.

Public Staff witness Metz explained that in relation to interconnection agreements (IAs), Contributions in Aid of Construction (CIAC) are funds provided to DEP by third party utility customers to pay for capital projects (usually new construction) typically requested by the third party. Tr. vol. 16, 452. Witness Metz testified that during his review of IAs between third party qualifying facilities (QFs) and DEP, he discovered that DEP had historically recorded QF developer CIAC payments as revenue rather than an offset to rate base. *Id.* Witness Metz stated that a QF developer is responsible for the cost of the network upgrades required for interconnection and that the costs are not socialized to all ratepayers unless otherwise permitted by law to ensure that the ratepayers are held harmless. *Id.* He explained that DEP performs a study to determine what network upgrades are necessary for the safe and reliable interconnection of the developer's project. DEP then charges the third-party developer for the construction costs of the identified network upgrades. *Id.* Witness Metz testified that ratepayers should be held harmless if the network upgrades are paid for in whole by the developer, plus any additional true up costs, once the project is online. *Id.* Witness Metz stated that the Public Staff attempted to determine the magnitude and resulting rate impact of this issue; however, more time was needed to audit, validate, and review this issue given the complexity. *Id.*

Witness Metz testified that DEP self-identified errors related to recording CIAC interconnection activity during a 2019 audit but deemed it as not material. *Id.* at 452-53. The audit findings stated that DEP's practice of recording CIAC from developers to the income statement as Other Revenue while charging costs incurred to complete construction to CWIP balance sheet accounts is incorrect. *Id.* at 453. To correct this issue, the audit findings instructed that the CIAC should be recorded to CWIP. *Id.* Witness Metz stated that DEP reviewed this topic again during a 2022 follow-up audit and that the audit

findings recognized that DEP's process improvements have strengthened tracking of the interconnection financial activity. *Id.* However, the audit findings determined that a comprehensive process documentation needs to be established to define roles and responsibilities and to ensure sustainability of the financial processes. *Id.* A deadline of June 2023 was established for DEP to prepare this documentation. *Id.*

Public Staff witnesses Zhang and Boswell testified that DEP booked these CIAC payments inconsistently, leaving the Public Staff unable to determine whether ratepayers were held harmless regarding the costs associated with these interconnections. Tr. vol. 19, 39. Witnesses Zhang and Boswell further testified that DEP changed its booking procedures for the fees received for interconnections at the beginning of 2022. *Id.* The Public Staff witnesses asserted that they were unable to determine the magnitude of the error, whether ratepayers have been harmed, and if so by how much or whether DEP's new procedures will alleviate the issues. Tr. vol. 16, 453; Tr. vol. 19, 39. Therefore, the Public Staff recommended that the Commission order DEP to produce all entries related to the IAs for all plant, depreciation, and collections so the Public Staff can determine whether ratepayers have been held harmless. *Id.* Additionally, the Public Staff recommended that a regulatory liability be established to record any instances in which DEP incorrectly recovered costs associated with IAs from ratepayers, to be flowed back to ratepayers with interest at DEP's weighted average cost of capital in the next DEP general rate case. *Id.* at 39-40. Witnesses Zhang and Boswell testified that since DEP had full control over its accounting systems and should have booked the amounts correctly, any items found to have been booked that should have been recovered from ratepayers should not be credited to the regulatory liability. *Id.* at 40. Witnesses Zhang and Boswell recommended that the Commission order DEP to review its CIAC policy and report the results of that review in the next general rate case. *Id.*

DEP witness Speros took exception to the Public Staff's recommendations and argued that the establishment of a regulatory liability has not been justified in this case. Tr. vol. 13, 60. Witness Speros explained that DEP has taken a number of steps to ensure CIAC associated with IAs is appropriately recorded on DEP's books. *Id.* He stated that this process begins with DEP's monthly reconciliation of associated liability accounts. *Id.* For Transmission projects, a monthly journal entry is made to credit capital projects for customer deposits based upon the cost incurred. *Id.* For distribution projects, quarterly journal entries are made to credit the capital projects for customers based upon costs incurred. *Id.* Witness Speros stated that DEP's project controls organization and finance organizations then work together to ensure that the current list of IA projects is appropriately analyzed so that proper journal entries are made, whether a debit or credit to the construction project. *Id.* Moreover, witness Speros explained that DEP continually works to improve its accounting processes, including the process for recording CIAC associated with IAs. *Id.* at 61. He commented that since 2019, DEP has taken steps to improve the processes in place for recording CIAC associated with IAs and made recent modification in 2022. *Id.* Witness Speros also explained that DEP has not been able to identify any interconnection costs associated with CIAC that ratepayers should not have been charged in DEP's last general rate case. Tr. vol. 13, 62.

Witness Speros also testified that the Public Staff's broad-based recommendation to order DEP to produce all entries related to IAs for all plant, depreciation, and collections is unnecessary to demonstrate that DEP's procedures are working properly. *Id.* at 61. In the alternative, DEP offered to work with the Public Staff in a collaborative fashion to facilitate their review and help identify information that would best provide a reasonable and efficient evaluation. *Id.* at 61-62. DEP also did not oppose in principle reporting to the Commission on its CIAC policy in the next general rate case. *Id.* at 63.

No other intervenors raised an issue regarding DEP's accounting for CIAC associated with IAs.

The initial Revenue Requirement Stipulation identifies as unresolved the issue of whether it is necessary for DEP to establish a regulatory liability to address CIAC for IAs as recommended by the Public Staff. As discussed below, the Commission concludes that the evidence in this case does not support the establishment of a regulatory liability to address CIAC collected by DEP from interconnection customers.

Fundamental to the establishment of a regulatory liability for CIAC related to IAs is a showing that the establishment of a regulatory liability is justified. In this case, the Public Staff offered very little in the way of justification to support the establishment of a regulatory liability. The Public Staff testified that it had found inconsistencies in the financial accounting of the CIAC related to IAs and that it was unable to determine whether ratepayers are being held harmless. Witness Metz acknowledged that the Public Staff needed more time to audit, validate, and review this issue given its complexity. Beyond these statements, the Public Staff witnesses were not in a position to demonstrate to the Commission the magnitude and rate impact on customers of this issue such that the establishment of a regulatory liability would be justified. Instead, the Public Staff requested that the Commission require DEP to produce all entries related to IAs for all plant, depreciation, and collections to allow the Public Staff to continue its audit of this issue beyond the conclusion of the present rate case proceeding.

The explanations provided by DEP witness Speros in his rebuttal testimony are informative as to the steps that DEP has taken to record CIAC for IAs in a manner that does not harm customers. As witness Speros explained, DEP has worked to improve its CIAC accounting procedures since 2019, with additional improvements made as recently as 2022. Further, as a result of the follow-up audit in 2022, a June 2023 deadline was established for DEP to document processes and define roles and responsibilities related to the financial accounting of CIAC related to IAs. The Commission determines that the requirement for DEP to construct this documentation should facilitate sustainability of DEP's improved financial processes. DEP should provide the Public Staff a copy of its documented processes related to this issue once the documentation is completed.

The Commission concludes that the Public Staff's proposal to establish a regulatory liability is not warranted at this time, given the uncertainty regarding the magnitude of the issue. In so concluding, the Commission gives weight to the testimony of witness Speros that

DEP has been unable to identify any interconnection cost associated with CIAC that ratepayers should not have been charged in DEP's last general rate case.

Based upon all of the evidence presented, the Commission concludes that the establishment of a regulatory liability is not justified by the record in this proceeding. DEP shall continue its work with the Public Staff regarding the documentation of its processes related to the recording of CIAC and shall report on the CIAC issue in its next general rate case application as required by the Revenue Requirement Stipulation.

EVIDENCE AND CONCLUSIONS FOR FINDING OF FACT NO. 71

Quality of Service

The evidence supporting this finding of fact is set forth in the testimony of DEP witnesses Guyton, Maley, and Quick and Public Staff witness T. Williamson.

DEP witnesses Guyton and Maley testified to the performance of the DEP transmission and distribution systems during the base period. Witness Maley testified that DEP's transmission system is reliable and well-maintained, and that DEP is seeking to continue transmission investments to facilitate the conversion of the transmission system to meet future demands. Witness Maley further indicated that DEP utilizes the System Average Interruption Duration Index (SAIDI) and System Average Interruption Frequency Index (SAIFI) metrics to measure outage durations and that these metrics over the base period showed a downward trend in outages (and therefore an upward trend in reliability). Witness Maley indicated that the transmission system also utilizes an Outages per Hundred Miles per Year – Sustained Automatic (OHMY-SA) metric which has further demonstrated the reliability of the DEP transmission system. Tr. vol. 10, 176-77. Witness Guyton testified that DEP's operational investments since its last rate case have allowed it to meet its operational performance and customer satisfaction goals and that it is providing safe and reliable service. *Id.* at 48. Witness Guyton also cited DEP's SAIDI and SAIFI scores as indicative of increasing system reliability in the form of reduced customer outages. He attributed this improvement in outage experience to ongoing grid improvements such as Self-Optimizing Grid improvements as well as ongoing vegetation management activities. *Id.* at 50.

In his direct testimony, Public Staff witness T. Williamson largely concurred with DEP's conclusions about improving service quality and attributed the stable to improving system performance to DEP's Grid Improvement Plan and vegetation management activities. Tr. vol. 21, 222. Witness T. Williamson also engaged in an in-depth analysis of DEP's service quality in which he examined various aspects of DEP's performance in initiating new service, providing normal day-to-day service, and restoration of service after outage events. *Id.* at 218-33. Witness T. Williamson also summarized various consumer statements of position filed with the Commission relative to this rate case. *Id.* at 233-35.

Regarding the initiation of new service, witness T. Williamson indicated that new service installations had almost doubled from 2015 through 2022 but that DEP's average

percentage of installations completed within 20 days had improved in recent years from historic averages and was in the low to mid 90s from 2020 forward. Witness T. Williamson also noted that the sheer number of new connections experienced by DEP in 2022 was having an impact on the ability to complete new installations quickly but that DEP still averaged to meet the 20-day goal 92.6% of the time in 2022. Witness T. Williamson also noted that "[t]he average business days to construct [new connections] has been consistently around the 10-day range and the average percent within 20 days has been consistently around the 95% range since 2019." *Id.* at 219-20. Regarding day-to-day service, witness T. Williamson reiterated that SAIDI and SAIFI scores have been trending downward since 2017 in part because of GIP program implementation which "provides a level of predictability concerning future service levels, to the benefit of customers. *Id.* at 222. Witness T. Williamson further testified that service reliability as measured by ASAI[22] has consistently measured more than 99.97% since 2013. *Id.* at 226. With respect to restoration of service after an outage, witness T. Williamson testified that DEP's Estimated Time to Restoration for service outages was met in 92% of Major Event Day outages. *Id.* at 232.

In her direct testimony, DEP witness Quick testified that in addition to DEP's primary responsibility of providing safe and reliable service, DEP understands that its customer base has diverse service needs and strives to recognize and accommodate them where possible. Tr. vol. 7, 67-68. She outlined the steps that DEP is taking to continue to improve customers' experiences and satisfaction. Tr. vol. 7, 65. With respect to DEP's customer care operations, witness Quick explained that they designed and continuously enhanced to ensure that customer inquiries are answered promptly and accurately. Customer calls are either processed in the Interactive Voice Response (IVR), allowing customers to self-serve, or by a call center specialist. Tr. vol. 7, 67. She also described how DEP uses social media channels to inform customers about reliability updates in their area and changes that could impact their bills. Additionally, in an emergency or major storm, DEP uses social media to communicate essential information to customers, making proactive posts to quickly warn as many customers as possible and engage with customers who have storm- or outage-related questions. Tr. vol. 7, 69-70.

Witness Quick also testified about the programs that DEP supports to help customers with the affordability of electric utility service. She noted the energy efficiency programs that help reduce energy usage and provide weatherization assistance. Tr. vol. 7, 71-73. She also detailed DEP's numerous efforts to support customers during the unprecedented COVID-19 pandemic. One example she gave was DEP's expansion and extension of the Winter Moratorium, a period from November until March every year where qualified customers are protected from disconnection for non-payment. DEP ensured the Winter Moratorium remained in place from November 2020 until March 2022, protecting approximately 48,000 eligible customers from disconnection during the initial and subsequent COVID-19 pandemic waves. Another example was the outreach campaigns to municipal leadership, community stakeholders, Chambers of Commerce, state agencies, food banks, and churches where

[22] ASAI is the ratio of the total number of customer hours that service was available during a given time period to the total number of customer hours demanded. Algebraically, this ratio is represented as follows: ASAI = 1 – (SAIDI/8760).

DEP communicated with customers to promote options for assistance and contacting DEP. Tr. vol. 7, 81-88.

Witness Quick further testified about recent digital enhancements to improve service to customers. She relayed that after receiving customer feedback, DEP improved its website by making interaction operations easier to locate in January 2022. Additionally, she described an interactive Transmission Map that details transmission projects planned across North Carolina, a planned vegetation management map, a feature alerting customers to estimated call wait times, the ability for customers to start and stop service online, and a digital, and a self-service enrollment option for payment arrangements. Moreover, witness Quick highlighted that DEP's digital enhancements made it easier for customers to report service interruptions. She also testified that DEP offers a fee mobile app that allows residential and small business customers to easily manage their account from anywhere in the United States. Witness Quick stated that since making these changes, customers are reporting higher satisfaction with their web experiences. Tr. vol. 7, 96-105.

In recognition of the policy of the State of North Carolina "to promote adequate, reliable and economical utility service" codified at N.C. Gen. Stat. § 62-2(2) and in accordance with the Commission's general supervisory authority established in N.C. Gen. Stat. § 62-32, and recognizing that the Commission found DEP's service quality to be "good" in the 2019 Rate Case and that the performance metrics for service rendered have not declined and, in some cases, have improved since that rate case, as is reflected in witness Williamson's testimony, the Commission concludes, based on the record in this proceeding, that the quality of service provided by DEP's is good. No other party presented evidence on DEP's service quality.

Additionally, no other party presented evidence critical of DEP's quality of service. Based on the foregoing, the Commission concludes that DEP provides adequate service to customers.

EVIDENCE AND CONCLUSIONS FOR FINDINGS OF FACT NOS. 72-73

Tax-Related Items

The evidence supporting these findings of fact is contained in DEP's verified Application and Form E-1; the testimony and exhibits of DEP witness Jiggetts, Public Staff witnesses Zhang and Boswell; and the entire record in this proceeding.

In its Application, DEP proposes to revise the EDIT-4 rider to return an additional $16.2 million for unprotected federal EDIT and $4.5 million for deferred revenues to customers over the remaining 2.7 years of the total five years to return the unprotected federal EDIT approved in the prior rate case. The two-year period for Deferred Revenues under EDIT-3 will expire in June of 2023; therefore, DEP is proposing to flow the additional amounts back to customers over the remaining life of the EDIT-4 rider in lieu of creating a new decrement rider. *Id.*

DEP witness Jiggetts supports this revision to the EDIT-4 Rider in her direct testimony and in Jiggetts Exhibit 3. Tr. vol. 13, 164. The Public Staff agrees with DEP's proposal to flow back the incremental amount to customers on a levelized basis over the remaining EDIT rider term; however, the levelized return rate used by the Public Staff reflects DEP's 3.88% cost of debt rate and a return on equity of 9.25% from December 31, 2022. Tr. vol. 23, 107.

In her third supplemental testimony, witness Jiggetts updated DEP's cost of debt to 4.03% as of March 31, 2023, and recalculated the proposed changes to the EDIT-4 Rider accordingly. Tr. vol. 13, 240, 242. In the initial Revenue Requirement Stipulation, the stipulating parties agree to an embedded cost of debt of 4.03%. Revenue Requirement Stipulation § III.1, Tr. Ex. vol. 7.

Based on the foregoing, the Commission concludes that DEP's proposal to revise the EDIT-4 Rider to return additional unprotected federal EDIT to customers over the remaining life of the EDIT-4 Rider, as supported by the Public Staff, is just and reasonable and should be approved. Further, the Commission finds and concludes that the levelized return rate should be based on the 4.03% embedded cost of debt agreed to by the stipulating parties in the initial Revenue Requirement Stipulation and the capital structure and rate of return on equity approved by the Commission in this proceeding.

EVIDENCE AND CONCLUSIONS FOR FINDINGS OF FACT NOS. 74-75

Equal Percentage Allocation, Base Fuel and Fuel-Related Factors and Fuel Cost Allocation

The evidence supporting these findings of fact is contained in DEP's verified Application and Form E-1; the testimony and exhibits of DEP witnesses Hager, and Jiggetts, the testimony of Public Staff witnesses Lucas, and McLawhorn, and Zhang and Boswell, and the testimony of CIGFUR witness Phillips, and the entire record in this proceeding.

In its Application and Form E-1, the fuel rates presented by DEP were allocated to customer classes utilizing the equal percentage fuel adjustment.

Public Staff witness Lucas testified that DEP currently allocates fuel cost adjustments to customer classes based on an equal percentage change, meaning that fuel and fuel-related costs are recovered using a uniform percent increase or decrease per rate class such that each rate class will, on average, experience the same average monthly percent increase or decrease as the overall fuel and fuel-related cost change. Tr. vol. 20, 28. Public Staff witness Lucas testified that since 2008, DEP has allocated fuel cost increases on an equal percentage basis to each of its five customer classes as allowed by Session Law 2007-397. Tr. vol. 20, 28. He testified that the Public Staff first supported the use of equal percentage allocation in DEP's 2008 fuel adjustment proceeding, Docket No. E-2, Sub 929. He cited several reasons for the Public Staff's agreement to the equal percentage allocation, such as the uncertain economic times and

the large increase in fuel costs. *Id.* at 29-30. He noted that the equal percentage method of adjusting rates assisted industrial customers financially during the Great Recession and during a period of unprecedented increases in coal prices at the expense of other customers. Id. at 28-31. He testified that the distortion that can be created by equal percentage fuel adjustments is found in DEP's most recent 2022 fuel rider proceeding, in which fuel costs increased for all customer classes except LGS, which received a fuel rate decrease. Id. at 30-35. He explained that, for this reason, it is the Public Staff's recommendation that the Commission does not allow DEP to make equal percentage fuel adjustments but allow DEP to continue to offer voltage differentiated rates. *Id.*

Witness Lucas stated that N.C.G.S. § 62-133.16(b) requires the Commission to allocate the utility's total revenue requirement among customer classes based on the cost causation principle and minimize cross subsidies "to the greatest extent practicable." *Id.* at 33-35, 53, 103. Witness Lucas noted that the statute defines the cost causation principle to mean "establishment of a causal link between a specific customer class, how that class uses the electric system, and costs incurred by the electric public utility for the provision of electric service." *Id.* at 33.

Witness Lucas presented the current fuel rates adjusted to remove the equal percentage allocation method. *Id*. at 36. As set forth in his Table 4, the rates in cents per kWh, excluding the regulatory fee, are 2.647 for residential customers, 2.654, for SGS customers, 2.609 for MGS customers, 2.516 for LGS customers, and 2.511 for Lighting customers. *Id.* at 36.

In his direct testimony, CIGFUR witness Phillips provided support for the equal percentage methodology. Tr. vol. 21, 487-88. He testified that the methodology has been approved without objection by any party in every annual fuel charge adjustment proceeding since 2008 and that the method has served ratepayers well and should be continued to be utilized. *Id.* He further stated that the methodology levelizes over time any harsh impacts and results in equal percentage increases or decreases to all customers, which are fair, just, and reasonable. *Id.*

The Commission notes that in DEC's annual fuel proceeding, DEC and the Public Staff agreed that DEC should continue to utilize the equal percentage fuel adjustment for purposes of that case. *See* Agreement and Stipulation of Partial Settlement, Docket No. E-7, Sub 1282 (filed May 31, 2023). The Commission further notes that there is not a similar agreement filed in the DEP annual fuel proceeding in Docket. No. E-2, Sub 1321.

Based on all the evidence in this proceeding, the Commission concludes that use of the equal percentage method of allocating fuel and fuel related costs does not follow the cost causation principle. In reaching this conclusion, the Commission gave substantial weight to the testimony of the Public Staff regarding the cost causation principle set forth in N.C.G.S. § 62-133.16, as well as their demonstration of the distortion that can be created by equal percentage fuel adjustments. Further, the Commission finds that this change shall be implemented for fuel rider proceedings filed after the date of this Order, and shall not apply in DEP's pending fuel adjustment proceeding, Docket No. E-2, Sub 1321.

Base Fuel and Fuel-Related Cost Factors

DEP's Application explained that the rates set forth in the exhibits to the Application included a base fuel and fuel-related rate of Residential - 2.126 cents per kWh; SGS - 2.111 cents per kWh; MGS 2.169 cents per kWh; LGS- 2.019 cents per kWh; and Lighting - 1.682 cents per kWh, excluding the Experience Modification Factors as approved in Docket No. E-2, Sub 1272 and excluding regulatory fees.

Witness Jiggetts testified DEP made an adjustment (Adjustment No. NC2010) to test period fuel expense to match the fuel clause revenues included in pro forma Adjustment No. NC1010. Tr. vol. 13, 180-81. She explained that by matching the expenses to the revenue, the adjustment ensures that no increase is requested in this proceeding related to fuel and fuel-related costs that are recoverable through the fuel clause. *Id*. She further stated that DEP intended to update this pro forma adjustment once it received an order in its pending fuel case in Docket No. E-2, Sub 1292. *Id.*

In her supplemental direct testimony, witness Jiggetts explained that DEP had updated pro forma Adjustment No. NC2010 to include revisions to reflect the fuel rates approved under in Docket No. E-2, Sub 1292. Tr. vol. 13, 221.

In her second supplemental direct testimony, witness Jiggetts testified that DEP had made a new adjustment (Adjustment No. NC2020 to adjust the nonfuel component of purchased power expense to reflect the impacts of the Stipulation Regarding the Proper Methodology for Determining the Fuel Costs Associated with Power Purchases from Power Marketers and Others reached with DEP, DEC and the Public Staff in Docket No. E-7, Sub 1282. Tr. vol. 13, 235. She further explained that during the test year, 39% of purchased power energy costs were estimated to be non-fuel expense and appropriate for cost recovery through base rates. *Id.* Based on the stipulation, during the test year, 15% of energy costs from these power purchases is the appropriate percentage to be deemed as non-fuel costs and appropriate for cost recovery through base rates. This pro forma adjustment makes the required reduction to operating expense in the test year as agreed upon with the Public Staff. *Id*.

The Commission issued a final order in the Sub 1292 fuel rider proceeding on November 3, 2022. In the Sub 1292 order, the Commission concluded that, effective for service rendered on and after December 1, 2022, DEP shall adjust the base fuel and fuel-related cost factors in its North Carolina retail rates, as approved in the 2019 Rate Case, amounting to 2.080¢/kWh for the Residential class, 2.126¢/kWh for the SGS class, 2.228¢/kWh for the MGS class, 2.204¢/kWh for the LGS class, and 1.392¢/kWh for the Lighting class (all excluding the regulatory fee), by amounts equal to 0.728¢/kWh, 0.971¢/kWh, 0.352¢/kWh, (0.066¢)/kWh and 1.984¢/kWh, respectively, and further, that DEP shall adjust the resulting approved prospective fuel and fuel-related cost factors by EMF increments/(decrements) of 0.649¢/kWh for the Residential class, 0.449¢/kWh for the SGS class, 0.586¢/kWh for the MGS class, 0.898¢/kWh for the LGS class, and 0.834¢/kWh for the Lighting class (excluding the regulatory fee). The Commission further

ordered that the EMF increments are to remain in effect for service rendered through November 30, 2023.

In the direct testimony of Public Staff witnesses Zhang and Boswell, they also used the fuel rates approved in Docket No. E-2, Sub 1292 to update revenues and expenses to May 2023 levels. Public Staff Accounting Ex. 1, Schedule 3-1(b)(1), Tr. Ex. vol. 19. In their Supplemental and Stipulation testimony they included an adjustment to fuel costs to reflect the impact of witness Lucas' recommendation to eliminate the equal percentage change in fuel rates. Tr. vol. 19, 91.

The only party that submitted evidence in this proceeding using fuel rates other than those approved in Docket No. E-2, Sub 1292 was the Public Staff. However, as shown on Public Staff Accounting Supplemental and Settlement Exhibit 1, Schedule 3-1(b), they adjusted fuel expense and revenue by the same amount so that there was no impact on the revenue requirement in this proceeding. *Id.* Also, Public Staff witness Lucas recommended that such rates be implemented effective December 1, 2023. No party offered any evidence contesting the testimony of witness Jiggetts that specifically supported the base fuel and fuel-related cost factor proposed by DEP. Accordingly, the Commission concludes for purposes of this proceeding that the total of the approved base fuel and fuel-related costs factors, by customer class — the sum of the respective base fuel and fuel-related costs factors set in the 2019 Rate Case and the annual non-EMF fuel and fuel-related costs riders approved by the Commission in Docket No. E-2, Sub 1292 — are just and reasonable to all parties in light of all the evidence presented.

Fuel Cost Allocations

In DEP's previous general rate case, the parties agreed on production plant as an appropriate allocation factor for purchased power capacity costs. Tr. vol. 11, 107. Under N.C.G.S. § 62-133.2(a2)(2), the Commission shall determine how these costs shall be allocated in a general rate case for the electric public utility. Therefore, this proceeding is the appropriate forum for the Commission to reconsider the appropriate cost allocation methodology for such costs, which are to be requested for cost recovery in DEP's annual fuel proceeding.

Witness Hager testified that DEP is proposing that the Commission use production demand as the more appropriate factor to allocate purchased power capacity costs to North Carolina retail and across North Carolina retail customer classes. Tr. vol. 11, 107. She testified that allocation based on production demand is more appropriate than production plant because purchased power capacity costs that are not recovered through the fuel clause are allocated on production demand. *Id.* She testified that the change towards allocation based on production demand would align all purchased capacity costs under the same allocator. *Id.* Additionally, most production plant is allocated on production demand, except for jurisdiction-specific amounts that are not related to purchase power costs. *Id.*

No party offered testimony opposing DEP's recommendation.

In DEP's previous general rate case, the parties agreed on production plant as an appropriate allocation factor for purchased power capacity costs. Tr. vol. 11, 107. Under N.C.G.S. § 62-133.2(a2)(2), the Commission shall determine how these costs shall be allocated in a general rate case for the electric public utility. Therefore, this proceeding is the appropriate forum for the Commission to reconsider the appropriate cost allocation methodology for such costs, which are to be requested for cost recovery in DEP's annual fuel proceeding. Based upon the evidence presented in this case, the Commission finds and concludes that the same production demand allocation method approved for production demand costs in this case using the 12 CP methodology at NC retail and the Modified A&E methodology for NC retail classes is the most appropriate methodology for allocating purchased power capacity costs in DEP's annual fuel proceeding.

EVIDENCE AND CONCLUSIONS FOR FINDINGS OF FACT NOS. 76-77

Residential Decoupling Mechanism and Earnings Sharing Mechanism

The evidence supporting these findings of fact is contained in DEP's verified Application and Form E-1; the testimony and exhibits of DEP witnesses Abernathy, Bateman and Stillman, Public Staff witnesses D. Williamson and Thomas, AGO witness Nelson, and the entire record in this proceeding.

Summary of Evidence

DEP's PBR Application seeks approval of performance-based regulation through the proposed three-year MYRP beginning on October 1, 2023 and ending September 30, 2026. DEP witness Bateman testified that in addition to the three-year MYRP, which includes an ESM, DEP's PBR Application also includes PIMs a decoupling mechanism for the residential customer class. Tr. vol. 14, 76. Witness Bateman explained that the PBR approach and DEP's PBR Application better aligns customer and state policy goals with utility revenues and performance than traditional ratemaking. *Id.* at 80.

Residential Decoupling Mechanism

DEP witness Abernathy provided direct testimony on the proposed decoupling mechanism. She testified that the "decoupling rate-making mechanism" is intended to break the link between an electric public utility's revenue and the level of consumption of electricity on a per customer basis. She explained that the following Rate Schedules are affected by the decoupling mechanism: RES, R-TOU, R-TOUD, and R-TOU-CPP, along with any new residential rate schedules approved by the Commission during the Plan Period. She testified that the Residential Energy Conservation Discount Rider is also impacted by decoupling. She testified as to how the annual and monthly target revenue per customer would be calculated for Rate Years 1, 2 and 3. She also testified as to estimated number of residential customers for each year and for each month for each rate year. She also explained that the difference between target residential revenues and actual residential revenues would be deferred, which would be adjusted to account for DSM/EE net lost revenues and incremental EV revenues. She also explained how the

carrying cost on the deferral would be calculated. She explained how the Decoupling Rider will work and DEP's reporting obligations with respect to the deferred balance. Tr. vol. 13, 102-12.

AGO witness Nelson also supported using a lower carrying cost rate on the decoupling deferral amount and placing a hard cap of 3% on surcharges. Tr. vol. 18, 82-83. Witness Nelson explained that a hard cap would limit rate increases and promote cost containment. *Id*. at 84.

The Public Staff expressed only one concern regarding DEP's proposed decoupling mechanism. Public Staff witness Nader testified that N.C.G.S. § 62-133.16 authorizes the Commission to approve a residential decoupling mechanism designed to break the link between revenues and the consumption of electricity. Witness Nader also testified that the statute also the utility with an opportunity to exclude rate schedules or riders associated with EV charging from sales calculations for purposes of the mechanism. Tr. vol. 21, 110-11. Witness Nader objected to how DEP determined the estimate of EV sales for the calculation and recommended that the decoupling mechanism not include DEP's proposed "Incremental EV Revenue Adjustment". *Id.* Witness Nader asserted that the estimate was "highly speculative" and that the decoupling mechanism should only include the adjustment for EV sales when more accurate EV sales data are available. *Id.* He recommended that DEP use a lower kWh per EV estimate than DEP proposed initially.

AGO witness Nelson asserted that DEP's proposal to exclude EV sales from its decoupling mechanism is not in the public interest. Tr. vol. 18, 72-73. Witness Nelson asserted that there is no link between this proposal and the goal of advancing EV adoption. *Id.* at 74. Witness Nelson further stated that the calculation for EV sales is not accurate and recommended that the Commission reject DEP's proposal. *Id.* at 79.

DoD-FEA witness Blank recommended that the Commission deny DEP's proposal to remove EV sales from the ESM. Tr. vol. 21, 34. Witness Blank stated that the PBR Statute explicitly provides what a utility can exclude from the ESM calculation, and the statute does not list EV sales. Tr. vol. 21, 341.

In response to AGO witness Nelson's suggestion to institute a 3% hard cap on the amounts the utility is able to collect from customers, "decoupling cap," witness Abernathy testified that there is no basis for a cap in the statute, that a cap has only been authorized in a few states, and that there is no cap on the recovery of DSM/EE net lost revenues. Tr. vol. 23, 149-50. Witness Bateman's rebuttal testimony offered further support for the exclusion of EV sales from the decoupling mechanism. Tr. vol. 23, 161-62. Witness Bateman testified that adjusting the decoupling mechanism for EV sales allows the utility to retain incremental net revenues driven by EV growth, thereby directly connecting EV growth with net revenues. Witness Bateman explained that if the Commission precluded DEP from including an EV adjustment within the decoupling and ESM calculations, DEP's residential EV sales would be decoupled from the utility's margin, thus eliminating an

important incentive for the utility to encourage EV adoption and grow EV sales in between rate case filings. *Id.*

The PIMs Stipulation provides that the parties thereto agree to allow DEP to exclude all EV sales from the decoupling mechanism subject to the following two conditions: (1) that the parties work together to develop and file EV tariffs and/or programs to estimate and update the revenue associated with residential EV sales in DEP's service territory, within 90 days of the Commission's order in this docket, and (2) that DEP updates the kWh per EV estimate proposed by Public Staff witness Nader with actual, DEP-specific EV usage data in each future decoupling rider proceeding.

Witness Bateman explained that the PIMs Stipulation clarified how DEP will obtain data that will help it to better estimate revenue associated with incremental residential EVs. Tr. vol. 14, 155. Witness Bateman explained that the agreed-upon method entails using DOT data to derive the number of residential EVs in DEP's service territory, using 180 kWh per vehicle as the electric usage (a value DEP measured within the EV Make-Ready Program), and then applying the flat residential tariff rate to the average monthly EV usage amount to derive the amount of residential EV sales to exclude from the decoupling mechanism. Tr. vol. 23, 234. Thereafter, within 90 days of a Commission order in this proceeding, DEP will file tariffs or programs, and using the data from those tariffs and programs, will refine the analytics to update the number of EVs and the usage assigned to each vehicle. *Id.* at 233. Witness Bateman also stated that DEP will also use this agreed-upon method to exclude EV sales from the ESM. *Id*. at 234-35.

Earnings Sharing Mechanism

DEP witnesses Abernathy and Bateman testified in support of the ESM, which is a component of the MYRP. Tr. vol. 13, 112; Tr. vol. 14, 81. Witness Abernathy explained that if DEP's adjusted earnings exceed the authorized ROE established by the Commission in this rate case plus 50 basis points, those excess earnings, including a return calculated at the weighted average cost of capital, must be distributed to customers over a 12-month period via the annual ESM Rider. Tr. vol. 13, 112.

Witness Abernathy testified that, for purposes of the ESM calculation, DEP will adjust earnings for weather, DSM/EE incentives, PIMs, and EV sales. Tr. vol. 13, 113.

Witness Bateman that the ESM allocates risk away from customers and onto DEP, noting how the ESM distributes to customers 100% of earnings in excess of 50 basis points above the authorized ROE on an annual basis, without a corresponding ability for DEP to collect additional revenue from customers if the utility is underearning. Tr. vol. 14, 81.

Also, as noted above, witness Bateman explained that if the Commission precluded DEP from including an EV adjustment within the ESM calculations, DEP's residential EV sales would be decoupled from the utility's margin, thus eliminating an important incentive for the utility to encourage EV adoption and grow EV sales in between rate case filings.

During the expert witness hearing DEP witness Stillman also provided support for DEP's proposal to exclude EV sales from the ESM where he stated that the adjustment would further support the increased adoption of EVs. Tr. vol. 13, 151. Witness Bateman further explained that this is consistent with the policy goals in N.C.G.S. § 62-133, Commission Rules R1-17B(g)(1)(f) and R1-17B(g)(2), and Governor Cooper's Executive Order 246. *Id.* at 162.

In response to Commission questions, DEP witness Jiggetts, noted that the reports DEP currently files to show annualized return on equity for each quarter is a very high level report. Tr. vol. 13, 327. Currently, DEP provides the Commission with a quarterly surveillance report, the ES1, that shows the Commission approximately where DEP's earnings are as compared to what it is allowed to earn. Tr. vol. 13, 324. Witness Jiggetts explained that in preparing that report, DEP makes numerous simplifying assumptions in order to be able to provide the report to the Commission within the required timeframe. *Id.* Witness Jiggetts confirmed that the quarterly surveillance reports provide a "snapshot" at a high level that does not include several ratemaking adjustments that would be necessary to arrive at DEP's actual return on rate base. *Id.* at 327. DEP provides qualifying language in the quarterly reports indicating that the figures do not accurately reflect DEP's earnings. *Id.* at 329.

Commissioner Clodfelter followed up with witness Jiggetts by asking how the Commission and the Public Staff can obtain actual annualized historical returns on equity that DEP has achieved, not for ratemaking purposes. Tr. vol. 14, 35. Witness Jiggetts explained that to reach a figure that represents DEP's true earnings, the Commission would need to ask DEP to do more detailed reporting and make certain adjustments to reflect the expected ongoing earnings, rather than using the high-level assumptions DEP employs for the quarterly ES1 reports. *Id.* at 35-36. Commissioner Clodfelter noted that the Commission, in evaluating the ESM Rider, needs to know a baseline number of what DEP actually earned in order to determine whether DEP over-earned or under-earned, or whether the Commission should increase or decrease the rate of return, or leave it the same. *Id.* at 37.

Discussion and Conclusion

In general, the Commission concludes that the residential decoupling mechanism and the ESM proposed by DEP are consistent with the PBR Statute and with Commission rule. Further, the Commission concludes that DEP's proposal to exclude EV sales from the decoupling mechanism and the ESM, as modified by the PIMs Stipulation, is reasonable and should be approved. The Commission does not find it appropriate, for the reasons advanced by DEP witnesses Bateman and Abernathy, to impose a decoupling cap, or authorize a lower carrying cost on the decoupling deferral amount. The Commission notes that the TCA Stipulation provides that the $20 million adjustment in the revenue requirement agreed to in the stipulation will be included in the ESM for DEP.

The Commission notes that the current ES1 reports were not intended to be used as a method to evaluate the ESM Rider. The Commission further notes that Commission

Rule R1-17B(h)(1) provides for the filing of quarterly earnings reports that require certain enumerated information. The Commission directs DEP to work with the Public Staff to develop a quarterly reporting form for DEP's earnings that will enable the Commission to analyze the information and determine the appropriate application and operation of the ESM Rider. As part of this review, DEP and the Public Staff shall review the requirements of Commission Rule R1-17B(h)(1) and recommend any necessary changes.

EVIDENCE AND CONCLUSIONS FOR FINDING OF FACT NO. 78

Performance Based Regulation

The evidence supporting this finding of fact is contained in DEP's verified Application and Form E-1; the testimony and exhibits of DEP witnesses Abernathy, Bateman and Stillman, Public Staff witnesses D. Williamson and Thomas, AGO witness Nelson, and CUCA witness O'Donnell; and the entire record in this proceeding.

Summary of Evidence

DEP's PBR Application seeks approval of performance-based regulation through the proposed three-year MYRP beginning on October 1, 2023, and ending September 30, 2026. DEP witness Bateman testified that in addition to the three-year MYRP, which includes an ESM, DEP's PBR Application includes a residential decoupling mechanism, PIMs, and tracking metrics. Tr. vol. 14, 76. Witness Bateman explained that the PBR approach, in general, and DEP's proposed MYRP better aligns customer and state policy goals with utility revenues and performance than does traditional ratemaking. *Id.* at 80.

The Commission notes, as the Public Staff points out, that the PBR Statute represents a substantial supplement to the existing law related to electric public utilities, such as DEP, and provides DEP with a cost recovery framework that represents fairly significant departure from the traditional cost recovery paradigm that has served North Carolina's electric utilities and their customers well for many decades. Discussed below are four new concepts allowed for the first time in North Carolina under the PBR Statute.

First, electric public utilities in North Carolina are entitled to file a MYRP, which is "a rate-making mechanism under which the Commission sets base rates for a multiyear period that includes authorized periodic changes in base rates without the need for the electric public utility to file a subsequent general rate application …" N.C.G.S. § 62-133.16(a)(5). This approach is a departure from the adjusted historic test year and authorizes certain projections of cost in the setting of rates.

Second, electric public utilities, such as DEP, are now allowed to utilize a decoupling mechanism. Under the PBR Statute's decoupling mechanism, DEP is authorized to "defer to a regulatory asset or liability account the difference between the actual revenue and the target revenue for the residential class" and this variance will result in an annual adjustment to the residential customer classes' bills. N.C.G.S. § 62-133.16(c)(2).

Third, the PBR Statute creates an ESM, which allows the electric public utility to elect to file a new rate case under N.C.G.S. § 62-133 in the event its weather-normalized earnings fall below the authorized rate of return on equity and requires the utility to refund to customers all weather-normalized earnings in excess of the authorized rate of return plus 50 basis points. N.C.G.S. § 62-133.16(c)(1).

Fourth, the PBR Statute requires that the utility implement at least one performance incentive mechanism, which is "a rate-making mechanism that links electric public utility revenue or earnings to utility performance in target areas consistent with policy goals …" N.C.G.S. § 62-133.16(a)(6). PIMs are intended to encourage the types of behavior about which customers care, provide DEP with the opportunity to earn a reward to be collected from customers, and expose DEP to payment of penalties which are refunded to customers (subject to a cap). N.C.G.S. § 62-133.16(c)(4).

While certain of the mechanisms established in the PBR Statute are new to North Carolina, aspects of the law are familiar and well-known to the Commission. For example, the responsibility "[t]o make reasonable and just rates" has been the obligation of the Commission's predecessors since the 19th century. *See, e.g.*, 1899 N.C. Session Laws, Chapter 164, § 2. The requirement that rates be "fair both to the electric public utility and to the customer," set forth in N.C.G.S. § 62-133.16(d)(1)(a) mirrors the charge in N.C.G.S. § 62-133(a) that "the Commission shall fix such rates as shall be fair both to the public utilities and to the consumer." Moreover, N.C.G.S. § 62.133-16 explicitly preserves the Commission's existing rate-making authority, providing: "[n]othing in this section shall be construed to [ ] limit or abrogate the existing rate-making authority of the Commission …" N.C.G.S. § 62-133.16(g) (omission denoted via brackets and ellipses). And, significantly, the Commission has long been required to consider risks both to the electric utility and to its customers, as it is well-established policy in North Carolina "to provide fair regulation of public utilities in the interest of the public" as well as "to promote adequate, reliable and economical utility service to all of the citizens and residents of the State." N.C.G.S. § 62-2(1), (3).

When reviewing a PBR application, the PBR Statute requires the Commission must consider whether a PBR application:

a. Assures that no customer or class of customers is unreasonably harmed and that the rates are fair both to the electric public utility and to the customer.

b. Reasonably assures the continuation of safe and reliable electric service.

c. Will not unreasonably prejudice any class of electric customers and result in sudden substantial rate increases or "rate shock" to customers.

N.C.G.S. § 62-133.16(d)(1).

Elsewhere in this Order the Commission has ruled upon the specific requests of DEP regarding costs to be recovered, as well as the rate of return that DEP has an opportunity to earn. In approving costs for recovery and establishing the rate of return, the Commission has applied well-established law in attempt to put the utility in a position to maintain its system and level of service, in view of the very real challenges that lie ahead for DEP, to earn a fair return, in view of current economic conditions, and to compete in the marketplace for capital on reasonable terms and at times when a capital need arises. The Commission has considered the impact of changing economic conditions on customers, recognizing that certain of the utility's customers will struggle to afford electric utility service, and has endeavored to establish rates that achieve the foregoing objectives most economically. In addition, elsewhere in this Order, the Commission has considered the potential for prejudice to customer classes and accepts the cost allocation methods, as well as certain of the rate designs, proposed by the utility and modified by the various stipulations to be reasonable and not prejudicial to any customer class.

In addition to the requirements for consideration by the Commission set forth in N.C.G.S. § 62-133.16(d)(1), the PBR Statute provides guidance on other considerations the Commission may undertake, including, for example, whether the PBR application "reduces low-income energy burdens;" whether the PBR application "encourages DERs"; whether the PBR application "encourages utility-scale renewable energy and storage"; and whether the PBR application "encourages peak load reduction or efficient use of the system." N.C.G.S. § 62-133.16(d)(2). The Commission notes, for example, that the PIMs Stipulation, discussed in detail elsewhere in this Order, involves PIMs that are intended to increase numbers of customers enrolled in time-differentiated rates, to increase the number of net-metered interconnections, to encourage the interconnection of utility scale generation above DEP's estimated annual limits, and to enable large commercial and industrial customers to achieve clean/carbon free energy objectives. Each of these PIMs aligns with the considerations established in N.C.G.S. § 62-133.16(d)(2). The tracking metrics, agreed upon by the parties to the PIMs Stipulation, pertain to customer service, reliability and "beneficial electrification," all of which should inform the future development of PIMs that align with the guidance set forth in N.C.G.S. § 62-133.16(d)(2). In addition, elsewhere in this Order, the Commission discusses the CAP's proposed by DEP in this proceeding, aimed at proving customers in need of assistance with bill payment, as well as the Affordability Stipulation, which is intended to provide additional relief for customers who will struggle to afford the cost of electricity. These provisions of the PBR Application, as modified by the stipulations, align with the considerations of § 62-133.16(d)(2). Throughout the course of this proceeding, DEP has worked with parties to the proceeding to refine the elements of its PBR Application to better conform to the requirements of N.C.G.S. § 62-133.16(d)(1) and to more closely align with the guidance set forth in N.C.G.S. § 62-133.16(d)(2).

The PBR Statute provides that the Commission is authorized to approve a utility's PBR application "so long as the Commission allocates the electric public utility's total revenue requirement among customer classes based upon the cost causation principle . . . and interclass subsidization of ratepayers is minimized to the greatest extent

practicable by the conclusion of the MYRP period." N.C.G.S. § 62-133.16(b). As previously explained, the PBR Statute also requires that the Commission consider whether a PBR application: 1) assures that no customer or class of customers be unreasonably harmed and that the rates are fair both to the electric public utility and to the customer; 2) reasonably assures the continuation of safe and reliable electric service; and 3) will not unreasonably prejudice any class of electric customers and result in sudden substantial rate increases or "rate shock" to customers. N.C.G.S. § 62-133.16(d). During cross-examination by CIGFUR II, DEP witness Reed acknowledged that the PBR Statute requires DEP to minimize interclass subsidization. Tr. vol. 11, 330. However, witness Reed emphasized that the PBR Statute requires the minimization of interclass subsidization "to the greatest extent practicable," which, the Commission concludes, DEP has achieved. The Commission concludes that DEP's approach of gradually reducing the subsidies between classes by utilizing a variance reduction of 10% is reasonable and that the 10% variance reduction approach moves towards eventual rate parity/minimization of interclass subsidization while, at the same time, balancing the other requirements of the PBR Statute including that no class of customer is unreasonably harmed or faces a sudden and substantial increase in rates resulting in rate shock. The Commission agrees with DEP witness Reed who testified that DEP appropriately considered "competing priorities" such as cost causation, rate shock, and gradualism in proposing the 10% variance reduction. Tr. vol. 11, 320-21. The Commission does not agree with the recommendation of CIGFUR II witness Phillips' argument that a greater variance reduction is warranted in this proceeding, primarily in light of the harm that such a reduction would cause to certain customer classes. Specifically, DEP witness Reed explained that if DEP had employed a 25% subsidy reduction, as recommended by CIGFUR II witness Phillips, the proposed increase to the Residential class would increase from 9.9% to 10.4% and the proposed increase to the Lighting class would increase from 19.9% to 24.9%. Tr. vol. 11, 265. Thus, balancing its obligations under the PBR Statute to ensure allocation of revenue requirement based on cost causation, minimization of interclass subsidization, equitable treatment of customer classes, and avoidance of unreasonable prejudice and rate shock, the Commission concludes that DEP's PBR Application as amended by the stipulations and the various provisions of this Order, is in alignment with cost causation or reasonably headed that way, avoids unreasonable harm to any class of customers, and does not unreasonably prejudice an class of customers or otherwise result in rate shock.

For the foregoing reasons, and as discussed in greater detail throughout this Order, the Commission concludes that DEP's PBR Application, as modified by the stipulations and this Order, results in just and reasonable rates, is in the public interest, and is consistent with the criteria established in N.C.G.S. § 62-133.16.

EVIDENCE AND CONCLUSIONS FOR FINDING OF FACT NO. 79

Revenue Requirement

The evidence supporting this finding of fact is found in DEP's verified Application and Form E-1; the Revenue Requirement Stipulation; the TCA Stipulation; and the

Supplemental Revenue Requirement Stipulation; the testimony and exhibits of the witnesses, including DEP witness Jiggetts and Abernathy and Public Staff witness Zhang and Boswell; and the entire record in this proceeding.

The Revenue Requirement Stipulation, the TCA Stipulation, and the Supplemental Revenue Requirement Stipulation provide for certain accounting adjustments that parties have agreed upon and the Commission has approved in this Order. The stipulation issues that impact the revenue requirement in the Revenue Requirement Stipulation and the TCA Stipulation are detailed in in Jiggetts Partial Settlement Exhibit 2 (Tr. Ex. vol, 14) and the Public Staff Accounting Supplemental and Settlement Exhibit 1 Schedule 1 (Tr. Ex. vol 19), which provide sufficient support for the annual revenue required on the issues agreed to in the Revenue Requirement Stipulation. The stipulation issues that impact the revenue requirement in the Supplemental Revenue Requirement Stipulation are in the Supplemental Revenue Requirement Stipulation Exhibit 1 (Tr. Ex. vol 7).

After giving effect to the approved stipulations and the Commission's decisions on the Unresolved Issues, as discussed herein, the Commission finds that DEP should recalculate the required annual revenue requirement consistent with the Commission's findings herein withing 10 days of the issuance of this Order. DEP is further directed to file with the Commission the final revenue requirements for Rate Years 1, 2, and 3 in the same format as Jiggetts Partial Settlement Exhibit 1. The Commission directs DEP to work with the Public Staff to verify the accuracy of the calculations, and the filing should reflect the corrections identified by DEP and agreed upon by the Public Staff.

The Commission concludes the annual revenue requirement for DEP for Rate Years 1, 2, and 3 which reflect the approved stipulations and the Commission's decisions on the Unresolved Issues will allow DEP a reasonable opportunity to recover its operating costs and earn the overall rate of return on its rate base that the Commission has found just and reasonable upon consideration of the findings in this Order.

IT IS, THEREFORE, ORDERED as follows:

1. That the Revenue Requirement Stipulation, the COSS Stipulation, the TCA Stipulation, the PIMs Stipulation, the Affordability Stipulation, the MGS Partial Rate Design Stipulation, the LGS Partial Rate Design Stipulation, and the Supplemental Revenue Requirement Stipulation are accepted and approved, as detailed in this Order. The Power Quality Stipulation is not approved as detailed in this Order;

2. That the depreciation rates proposed by DEP in this case, which are based on the 2021 Depreciation Study and amended by the Revenue Requirement Stipulation, with such agreed upon amendments proposed by the Public Staff including the amortization periods for General Plant accounts 391 and 397, and the 70-year life of Transmission FERC account 356, shall be, and is hereby approved;

3. That DEP's request for an accounting order for approval to defer to a regulatory asset 75% of the impact of accelerating the retirement of DEP's Mayo and

Roxboro Units 3 and 4, as agreed upon in the Revenue Requirement Stipulation, preserving DEP's ability to recover 50% of the net book value of the subcritical plants through securitization, shall be, and is hereby approved;

4. That the remaining net book value of DEP's Mayo and Roxboro Units 3 and 4 at retirement shall be recovered with a return over the amortization period determined by the Commission in a future rate case;

5. DEP's plant-related capital investments in the base period fossil, renewable, storage, and nuclear fleet assets as adjusted in the Revenue Requirement Stipulation, shall be included in rates for the base period;

6. DEP's transmission and distribution investments made during the test period, as adjusted by the Revenue Requirement Stipulation, shall be included in rates for the base period;

7. That DEP's GIP investments shall be included for recovery in DEP's rates;

8. That in accordance with the Revenue Requirement Stipulation, DEP is permitted to recover the full balance of its GIP deferral over an 18-year amortization period, with a debt-only return during the deferral period and rate base treatment during the 18-year amortization period;

9. That DEP shall recover the balance of the CCR deferral, net of the over amortization, over a five-year amortization period with reduced financing costs during the amortization period calculated based on (1) DEP's cost of debt as approved in this Order adjusted as appropriate to reflect the deductibility of interest expense, (2) an ROE 150 basis points lower than the 9.8% ROE as approved in this Order, and (3) a capital structure of 48% debt and 52% equity as set forth in the CCR Settlement;

10. That in accordance with the Revenue Requirement Stipulation, DEP shall flowback to customers over a three-year period the liability related to the gains on Harris land sales;

11. That in accordance with the Revenue Requirement Stipulation, DEP shall continue to defer any gains on any future Harris land sales to return to customers in a future general rate case;

12. That DEP shall amortize the Roxboro Wastewater Treatment Facility regulatory asset over a period of twelve years and the unamortized balance shall be included in rate base;

13. That DEP shall amortize the regulatory liability for overcollections associated with storm securitization over a three-year period;

14. That the agreed-upon accounting adjustments outlined in the Revenue

Requirement Stipulation shall be, and are hereby, approved;

15. That DEP shall track and report on an annual basis the actual spend and employee head count for each coal generation station over the MYRP period in a manner to be agreed upon by DEP and the Public Staff. DEP shall update the Commission on the manner upon which DEP and the Public Staff have agreed to the tracking and reporting of the actual spend and employee head count for each coal generation station;

16. That DEP shall record any cumulative underspend less than $6 million (North Carolina retail) of annual incremental spend for ongoing O&M for DEP's coal generation fleet for discrete programs and targeted categories to a regulatory liability account accrued through the end of the MYRP period (September 2026) and return the underspend to customers in the next general rate case;

17. That DEP shall perform a lead-lag study before its next general rate proceeding and incorporate the results of that study in its next general rate case filing;

18. That DEP's proposed MYRP, reflecting the projected costs associated with the Transmission, Distribution, Fossil/Hydro, Nuclear, Cybersecurity, Solar, and Storage capital investments, as adjusted by the Revenue Requirement Stipulation, as reflected in Abernathy Partial Settlement Exhibits 1 and 2, is just and reasonable and adopted in its entirety;

19. That DEP has demonstrated a reasonable plan to timely complete the MYRP projects;

20. That DEP shall consult with the Public Staff to develop a report on Rider EC. DEP shall file its first report on Rider EC no later than one year from the date of this Order;

21. That DEP shall report on the issue of CIAC related to IAs in its next rate case application;

22. That DEP shall consult with the Public Staff to develop a report on reliability O&M as the Public Staff proposed. DEP shall file its first report on reliability O&M no later than one year from the date of this Order;

23. That DEP shall consult with the Public Staff to develop its Vegetation Management Program Performance report as provided in this Order;

24. DEP shall, in consultation with the Public Staff, file a report on the Hot Springs Cost Benefit Analysis;

25. That DEP may to recover through base rates DEP's costs associated with its DSDR program;

26. That DEP's request to establish the Payment Navigator program shall be, and is hereby approved;

27. That DEP shall be allowed to recover its costs to implement Customer Connect;

28. That the COSS Stipulation shall be, and is hereby approved;

29. That in its next general rate case, DEP shall provide a comprehensive justification for the use of a NCP demand instead of a coincident peak demand for any cost allocation purpose;

30. That the PIMs Stipulation is consistent with N.C.G.S. § 62-133.16 and Commission Rule R1-17B, achieves a measured balance between encouraging behavior and risk/reward to utility shall be, and is hereby approved;

31. That the Power Quality Stipulation, or the pilot program addressed therein, are not approved, but that DEP may file an application for such a pilot program in a separate proceeding;

32. That, consistent with the Affordability Stipulation, DEP's proposed CAP is hereby approved as a three-year pilot;

33. That DEP's proposed CAP and CAR Riders shall be, and is hereby approved;

34. That the shareholder financial contributions, detailed in the Affordability Stipulation, shall be, and is hereby approved;

35.; That DEP shall convene a stakeholder group to meet at least quarterly to consider data and reporting issues related to the CAP. The stakeholder group is directed to develop an annual report on the CAP as provided in this Order;

36. DEP is directed to file a report on the feasibility and proposed structure of a tiered customer assistance program the later of (i) 18 months after the date of this Order, or (ii) when there is one year of data from the CAP Rider;

37. DEP is directed to report on the Affordability Metrics established in this Order in the same manner as it reports on the tracking metrics agreed to in the PIMS Stipulation;

38. That DEP shall consult with the Public Staff to develop a report on the CAP including the number of CAP recipients, CAP administration costs, and the observed impacts of CAP on arrearage management and disconnections for nonpayment;

39. That the revisions to rate schedules, as proposed by DEP or as otherwise modified herein shall be, and is hereby approved;

40. That the revisions to the service riders, as proposed by DEP or otherwise specifically modified herein, including Rider EC and Rider NSC shall be, and is hereby approved;

41. DEP shall notify all SGS customers that customers may now elect the residential rate schedule for detached garages, barns, and other structures on the same residential premise currently served under a residential rate schedule;

42. That DEP shall inform all Schedule SLR customers that the schedule will not be open to new customers as of October 1, 2023;

43. That DEP shall provide via bill insert or separate mailing amendments to its Outdoor Lighting Service Regulations to all customers subject to those Regulations;

44. That DEP shall, before the next rate case, analyze the impacts of transferring customers receiving service under Riders 7 and 57 to other standby service riders and, if that analysis reveals viable options for transferring these customers, DEP shall propose a transition period in its next general rate case to move these customers to other standby service riders over a reasonable period and in a manner that lessens or avoids rate shock;

45. That DEP's rates during the MYRP Rate Period shall reflect a rate of return on equity of 9.8% and embedded cost of debt of 4.03% based on a capital structure consisting of 53% common equity and 47% long-term, for a rate of return of 7.09%;

46. That DEP's shall be allowed to recover certain COVID-related costs that have been deferred, including customer fees waived, bad debt charge-offs, and costs related to employee safety, netted against the COVID-related savings related to printing, postage, employee travel, and certain measures taken by the federal government that benefitted DEP during the pandemic, over a six-year period with no return on the unamortized balance during the amortization period, which shall begin on the effective date of the rates approved in this proceeding;

47. That DEP's request to continue the deferral of bad debt expenses related to the impact of the COVID-19 pandemic is hereby approved. That any payments associated with bad debt amounts should be credited on a monthly basis through the next general rate case proceeding. That DEP should report on a semiannual basis the actual amounts recorded to the deferral and the payments received;

48. That the inflation adjustment proposed by DEP shall be, and is hereby approved;

49. That DEP's request to recover costs incurred related to the Commission's Order in the 2019 Rate Case in the amount of $5.384 million, which are above and beyond the rate case costs provided for in the 2019 First Partial Settlement is hereby approved. Such costs shall be amortized over a three-year period;

50. That DEP is hereby allowed to recover over a three-year period rate case costs in the amount of $6.551 million related to the present proceeding;

51. That DEP's request to include the unamortized balance of rate case expense in rate base shall be, and is hereby denied;

52. That DEP's request to track actual rate case costs from the March 31, 2023 update cutoff date in this proceeding through the date rates become effective for possible recovery in a future rate case proceeding shall be, and is hereby denied;

53. That the following treatment with respect to over-amortizations of regulatory assets shall be, and hereby is approved for purposes of this proceeding:

a. The over-amortization of rate case expense from Docket No. E-2, Sub 1023 of $1,112,000 should be applied to the balance of rate case expense from the Commission's Order in the 2017 Rate Case of $530,000, which will eliminate that balance. The remaining $582,000 of over-amortization should be applied against rate case costs being requested in this proceeding.

b. The over-amortization of severance costs from the Commisioner's Order in the 2019 Rate Case in the amount of $907,000 should not be applied against the rate case costs being requested in this proceeding but instead should be refunded to customers through a one-year rider with interest.

c. The over-amortization of early retired plant in the amount of $13.8 million should be applied against the outstanding rate base balance for the Asheville early retired coal plant authorized in the 2019 Rate Case.

d. The over-amortization of Hurricane Matthew costs from the Commission's Order in the 2017 Rate Case in the amount of $17 million should be treated as follows: first, to recover 2022 incremental Winter Storm Izzy costs, and second, the remaining $2 million credit should be refunded to customers through a one-year rider with interest.

e. Over-amortization of regulatory fees in the amount of $68 thousand should be refunded to customers through a one-year rider with interest.

54. That if DEP receives revenue for any deferred cost for a longer period of time than the amortization period approved by the Commission for that deferred cost, DEP shall continue to record all revenue received for that deferred cost in the specific regulatory asset account established for that deferred cost until DEP's next general rate case for a determination of the appropriate ratemaking treatment of such over-amortizations;

55. That DEP is allowed to collect in rates its North Carolina Retail normalized annual level of storm costs in the amount of approximately $22.2 million;

56. That DEP's request for an accounting order for approval to establish a regulatory asset to defer the incremental costs incurred as a result of Winter Storm Izzy shall be, and hereby is approved;

57. That DEP shall be allowed to recover the 2022 incremental Winter Storm Izzy costs of approximately $15 million applying a portion of the over-amortization of Hurricane Matthew costs in the amount of $17 million from the Commission's Order in the 2017 Rate Case;

58. That the remaining amount of over-amortization of Hurricane Matthew costs of approximately $2.0 million, shall be returned to customers through a levelized rider over a period of one year;

59. That DEP's request for an accounting order for the storm balancing account shall be, and is hereby denied;

60. That DEP's request for an accounting order to defer any incremental revenue requirement impacts, including benefits and costs, associated with the IRA and the IIJA, shall be, and is hereby approved;

61. That DEP's request for an accounting order to defer implementation and administration costs associated with the CAP, Payment Navigator Program, and the Tariffed On-Bill program, and PIMs, shall be, and is hereby denied;

62. That the establishment of a regulatory liability as recommended by the Public Staff to address CIAC collected by DEP related to interconnection agreements is not warranted at this time, however, DEP shall report on the issue of how CIAC is recorded in the context of interconnection agreements in its next general rate case application as required by the Revenue Requirement Stipulation;

63. That the Commission finds DEP's provision of electric service to be adequate;

64. That DEP's proposed revisions to its previously approved North Carolina excess EDIT rider (EDIT-4) to reflect additional amounts due to customers, shall be, and is hereby approved, and that the leveled return rate shall be based on a capital structure consisting of 47% long-term debt and 53% equity, an embedded cost of debt of 4.03% and a rate of return on equity of 9.8%;

65. That DEP shall use the base fuel rates, exclusive of the equal percentage allocation, established above in the current (2023) annual fuel adjustment proceeding;

66. That the approved base fuel and fuel-related cost factors by customer class are as follows: 2.808 cents/kWh for the Residential class, 3.097 cents/kWh for the SGS class, 2.580 cents/kWh for the MGS class, 2.138 cents/kWh for the LGS class, and 3.376 cents/kWh for the Lighting class;

67. The production demand allocation method approved for production demand costs using the 12 CP method at NC retail and the modified A&E method for NC retail classes is the most appropriate method for allocating purchased power capacity costs in DEP's annual fuel proceedings;

68. That DEP's proposed residential decoupling mechanism is consistent with N.C.G.S. § 62-133.16 and Commission Rule R1-17B, and the proposed tariff for the associated rider, shall be, and is hereby approved;

69. That DEP's proposed ESM, as modified by the TCA Stipulation, is consistent with N.C.G.S. § 62-133.16 and Commission Rule R1-17B, and the proposed tariff for the associated rider, shall be, and is hereby approved;

70. That DEP shall file the final annual revenue requirements for Rate Years 1, 2, and 3 consistent with the Commission's findings and rulings herein within 10 days of the issuance of this Order in the same format as Jiggetts Partial Settlement Exhibit 1. DEP shall work with the Public Staff to verify the accuracy of the calculations;

71. DEP shall file schedules (North Carolina Retail Operations – Statement of Rate Base and Rate of Return, Statement of Operating Income, and Statement of Capitalization and Related Costs) with the Commission within 10 days of the issuance of this Order, summarizing the gross revenue and the rate of return that DEP should have the opportunity to achieve based on the Commission's findings and determination in this proceeding;

72. That DEP is authorized to adjust its rates and charges in accordance with the Revenue Requirement Stipulation, the TCA Stipulation, and the Supplemental Revenue Requirement Stipulation and findings in this Order effective for service rendered on and after the following date after the Commission issues an Order accepting the calculations required by Ordering Paragraph No. 70;

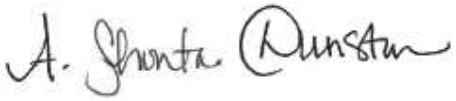
73. That within 30 days of this Order, DEP shall file for Commission approval all rate schedules designed to comply with this Order, accompanied by calculations showing the revenues that will be produced by the rates for each schedule; and

74. That DEP shall submit a proposed customer notice to the Commission for review and approval, and upon approval of the notice by the Commission, shall give appropriate notice of the approved rate increase by mailing the notice to each of its North Carolina retail customers during the billing cycle following the effective date of the new rates.

ISSUED BY ORDER OF THE COMMISSION.

This the 18th day of August, 2023.

NORTH CAROLINA UTILITIES COMMISSION



A. Shonta Dunston, Chief Clerk

Chair Charlotte A. Mitchell dissents in part. Commissioner Kimberly W. Duffley joins in Chair Mitchell's dissent in full. Commissioner Karen M. Kemerait joins in Chair's Mitchell's dissent with respect to the sections on rate of return of equity and the recovery of the deferred COVID-related costs.

Commissioner Daniel G. Clodfelter dissents in part and concurs in part.

DOCKET NO. E-2, SUB 1300

Chair Charlotte A. Mitchell, dissenting in part:

For the reasons set forth below, I dissent from the Order's resolution of the following three issues: rate of return on equity, the recovery of deferred COVID-related costs, and affordability – next steps.

I. Rate of Return on Equity

DEP requested a rate of return on equity (ROE) of 10.4%, and DEP witness Morin testified on cross examination that, due to a tapering in interest rates between the time of filing of his supplemental testimony and the hearing, his recommended rate of return on equity would have been 0.2% lower if recalculated. Tr. vol. 8, 324. The Order concludes that substantial evidence supports the reasonableness of a rate of return on equity ranging from 9.75% to 10.0%, without a downward adjustment due to the MYRP, and ultimately approves 9.8%. I would have approved an ROE of 10.0% for the following reasons.

First, I question whether the Commission regards 10.0% as a Rubicon across which the Commission must not go. I note that in a 2013 general rate case proceeding, DEP and the Public Staff entered into a settlement agreement which, among other things, included agreement on the ROE at 10.2%. Moreover, a historical review of Commission decisions in general rate cases reveals that this Commission has awarded ROEs in excess of 10.0% in many cases in the past. I do not point this out to indicate that an ROE of 10.2% then makes appropriate an ROE of 10.2% now, rather I point this out only to illustrate that the Commission, in the not-too-distant past, has crossed that "symbolic" threshold. *See* Order Granting General Rate Increase, *Application of Progress Energy Carolinas, Inc., for Adjustment of Rates and Charges Applicable to Electric Utility Service in North Carolina*, No. E-2, Sub 1023 (May 30, 2013).

Second, I am concerned that the results of the DCF models are inconsistent with the current capital market environment and bias downward the range of reasonableness presented in the Order. The three models most cited by the expert witnesses in this case – DCF, CAPM, and RPM – involve different approaches to estimating the cost of equity. However, there is a crucial difference between the DCF model and the other two models. While RPM and CAPM involve borrowing costs as a direct input to the model, DCF does not involve borrowing costs as a direct input. Thus, the outcome of the DCF is not directly affected or informed by borrowing costs. Rather, borrowing costs are considered only indirectly in the DCF model. Many of the experts relied on analyst estimates to inform the dividend growth rate, which is a key input to the DCF model, and while some unknown but correlated factor between dividend growth rates and borrowing costs could impact the outcome of the model, there is no input for borrowing costs. Although utility stocks can act somewhat like long-term fixed income securities, causing their prices to fall (and dividend yields to rise) when bond yields rise, that does not necessarily happen in lock-step. Too, the higher betas presently observed indicate that

utility stocks are relatively more correlated to stocks and less so to bonds than they were in the past. The point is that there are structural (i.e., as a result of the model inputs) reasons why the output of the CAPM and RPM will rise due to rising interest rates, when the DCF might not necessarily respond in the same way or to the same extent.

Undisputed in the record of this case is that long-term borrowing costs, both for DEP as well as the U.S. Treasury, have risen significantly and are at multi-year highs. During the pendency of this rate case, DEP's borrowing costs have risen from 3.7% to 4.03%, and since the Commission's decision in the Sub 1219 rate case, 30-year Treasury yields have increased from 2.16% to nearly 3.84% as of May 1, 2023. *See, e.g.,* Tr. vol. 9, 41; tr. vol. 22, 196.

The range of reasonableness identified by the Commission in this case equally weights the DCF, CAPM, and RPM, but of the three, only the DCF model produced results below the range and indicated the cost of equity is lower now than it was in the prior rate case, when the Commission ordered rates to be set using an ROE of 9.6%. Given that the record in this case reflects an increase in borrowing costs and given that the consensus of the DCF models remains below the approved ROE in the last rate case, the results deserve a certain amount of skepticism.

The Commission has at various times in the past placed more or less emphasis on a given model in order to reflect its conclusion as to whether the results of that model accurately reflect the utility's cost of equity. *See, e.g.*, Order Approving Partial Settlement Agreement and Stipulation, Deciding Contested Issues, Granting Partial Rate Increase, Approving Water and Sewer Investment Plan, and Requiring Customer Notice, *Application by Carolina Water Service, Inc. of North Carolina for Authority to Adjust and Increase Rates and Charges for Water and Sewer Utility Service in All Service Areas of North Carolina and Approval of a Three-Year Water and Sewer Investment Plan*, No. W-354, Sub 400, at 44 (Apr. 26, 2023); Order Granting Partial Rate Increase, *Application by Carolina Water Service, Inc. of North Carolina for Authority to Increase Rates for Water and Sewer Utility Service in All Its Service Areas in North Carolina*, No. W-354, Sub 128, at 77-78 (June 10, 1994). Because of the very clear signal sent by the bond market that the cost of capital has risen significantly, an ROE at the top end of the range of reasonableness, implicitly giving the DCF result less weight, is both warranted and necessary at this time.

Third, while the Order gives some acknowledgement to DEP's stressed credit metrics, I am concerned that the decision to approve an ROE of 9.8% will ultimately prolong that stress, leading, potentially, to a downgrade. A downgrade will cost customers. Tr. vol. 22, 186.

DEP witness Newlin explained that credit quality (or creditworthiness) is a term used to describe a company's overall financial health and its willingness and ability to repay all financial obligations in full and on time. Tr. vol. 9, 88. He went on to explain that two major credit rating agencies, Standard & Poor's (S&P) and Moody's Investors Service (Moody's), establish credit ratings for DEP.

Witness Newlin testified that DEP must be in a position to operate and maintain its business without interruption and to refinance maturing debt on time, regardless of financial market conditions. He noted that the financial markets can experience periods of volatility and that DEP must be able to finance its needs throughout such periods. He concluded that strong investment-grade credit ratings provide DEP with greater access to the capital markets on reasonable terms during such periods of volatility. *Id.*

In explaining the qualitative and quantitative factors that rating agencies would consider when assessing DEP's creditworthiness, he testified:

> Quantitative measures are primarily based on operating cash flow and focus on the level at which DEP maintains debt leverage in relation to its generation of cash and its ability to meet its fixed obligations (interest expense in particular) based on internally-generated cash. The percentage of debt to total capital is another example of a quantitative measure. Creditors and credit rating agencies view both qualitative and quantitative factors in the aggregate when assessing the credit quality of a company.

Tr. vol. 9, 90.

He also testified that investors, investment analysts and credit rating agencies, in assessing a utility company's financial strength, consider the allowed rate of return, the cash quality of earnings, the timely recovery of capital investments, the stability of earnings, and the strength of its capital structure. *Id*. at 91. Specifically with respect to ROE, he testified that the allowed return on equity is a key component in the generation of earnings and cash flows and that an adequate return on equity helps ensure equity investors receive fair compensation for their investment while also helping to protect the interests of debt investors. *Id.* at 96. He testified further that a strong capital structure and an adequate return on equity provide balance sheet protection and cash flow generation to support high credit quality. Moreover, he testified that high credit quality creates financial flexibility by providing more readily available access to the capital markets on reasonable terms, and ultimately lower debt financing costs, while a weak capital structure and an inadequate allowed return on equity produces lower earnings and cash flows, lowers credit quality, and may limit financial flexibility. *Id.*

On this record, I am persuaded that ROE is a critical component of creditworthiness. I am also persuaded that high credit quality serves the public interest by putting the utility in a position to compete for capital on the most reasonable terms available and by increasing the potential that the utility will be able to access the capital markets on reasonable terms during all types of market cycles, including periods of high volatility, which, ultimately, lowers borrowing costs passed through to customers.

The Order discusses DEP's stressed credit metrics in the context of capital structure and notes:

> Specifically regarding DEP, Moody's has taken two very recent actions, both of which highlight the immediate credit metric challenges DEP faces. First, in April 2023 Moody's published a "Ratings Action" report (DEP Redirect Newlin Direct Exhibit 1) affirming DEP's A-level rating but at the same time issuing an explicit warning with regard to the principal credit metric utilized by Moody's, the ratio of Funds From Operations (FFO) to debt (FFO/Debt)[1]. In its April 2023 Ratings Action Moody's indicated that it was raising its FFO/Debt downgrade threshold for DEP from 20% to 21% (*Id.* at 4), meaning that while it had in the past forecast a potential downgrade in DEP's credit rating if the FFO/Debt metric stayed below 20% on a sustained basis, it was now forecasting a potential downgrade if the metric stayed below 21% on a sustained basis. This is a particularly worrisome development because, as Company witness Newlin pointed out during his direct testimony, DEP's FFO/Debt ratio has been below 21% for a number of years. Tr. vol. 9, 17-18. In other words, DEP is already operating below the Moody's raised downgrade threshold and has already been doing so on a sustained basis. *Id.* at 18-19.
>
> Between witness Newlin's appearance on direct (May 5) and his appearance on rebuttal (May 16), Moody's issued its May 2023 updated Credit Opinion regarding DEP (DEP Redirect Newlin Rebuttal Exhibit 1), replacing its Credit Opinion issued in March 2022 (introduced into evidence as both Public Staff Cross-Examination Morin Direct and Rebuttal Exhibit No. 15 and DEP Redirect Newlin Direct Exhibit 2). In the updated Credit Opinion, Moody's explicitly referenced as factor that could lead to a downgrade the FFO/Debt ratio "remaining below 21% in 2023." DEP Redirect Newlin Rebuttal Exhibit 1, 2; *see also* Tr. vol. 23, 36-37. Accordingly, Moody's not only alluded to its raised download threshold, but pointedly referenced 2023—this very year.

The Order goes on to note that "the potential for downgrade is not a theoretical issue" and characterizes the Moody's actions as "a series of escalating warnings."

However, I do not agree that an ROE of 9.8%, on this record and at this time, takes those warnings seriously. Even with an equity layer of 53.0%, an ROE of 9.8% does not put the utility in a position to address the challenges it faces.

As was testified to extensively in this proceeding, in November 2022, Moody's placed the entire electric sector on negative outlook as a result of a number of factors including higher fuel costs, higher interest rates, large capital spends, and inflation.

[1] In Moody's parlance FFO/Debt is called "preworking capital cash flow to debt," Tr. vol. 9, 115, or "CFO pre-WC to debt." Both FFO and CFO pre-WC mean the same thing and are a measure of cash flow. *Id.*

Tr. vol. 10, 23. In doing so, Moody's noted that financial metrics for the industry at large are already under pressure with little cushion entering 2023. Subsequent to that action, as mentioned above, Moody's took action with respect to DEP specifically, changing the downgrade threshold from 20% to 21%. *Id.* at 15. The evidence of record demonstrates that DEP is below the downgrade threshold now. Tr. vol. 9, 112.

DEP faces substantial capital needs over the next several years to comply with environmental requirements, to replace and upgrade aging infrastructure, to construct or acquire new generation resources, to upgrade the transmission system, and to satisfy its debt maturities. DEP's capital requirements, including MYRP projects, for the next five years (2022-2026) are projected to be approximately $13.6 billion, which includes $1.3 billion in debt retirements. *Id.* at 98. In the very near term, DEP must retire $300 million of first mortgage bonds, which are due in September 2023. DEP Redirect Newlin Direct Ex. 1, Tr. Ex. vol. 23. DEP witness Newlin testified that DEP's capital requirements, including MYRP projects, are expected to be funded from internal cash generation, the issuance of debt, and equity funding from Duke Energy, as needed. Tr. vol. 9, 98. He explained further that DEP is in a growth cycle, due to the Carbon Plan, and that, while not unusual for utilities in a growth cycle, DEP is a cash flow negative company, which means that its source of funds will not necessarily be limited to debt issuance but must include other sources, such as retained earnings from lowering the dividends paid to the parent or even equity injections from the holding company. *Id.* at 110.

Recognizing some of the challenges ahead for DEP, in a May 2023 credit opinion, Moody's noted that recovery of ongoing coal ash remediation costs and storm costs, along with elevated spending for grid modernization, will maintain pressure on credit metrics. DEP Redirect Newlin Rebuttal Ex. 1, Tr. Ex. vol. 23.

DEP witness Newlin testified that the heightened level of market volatility and uncertainty created by events of recent years have led to an unprecedented number of zero issuance days in the primary debt capital markets. Specifically, he testified that there were 48 zero issuance days in 2022 and already 11 such days to start 2023. Tr. vol. 22, 196. During the hearing, he testified as to a specific recent example, which occurred during the week of the Silicon Valley Bank collapse and sale of Credit Suisse to UBS. He explained that while DEP teed up with two other issuers within the Duke complex to issue that week, the market was very unsettled and they were unable to or decided not to issue into that market. *Id.* at 206. Additionally, evidence in the record, which was not rebutted, shows that borrowing costs increase as credit quality decreases. DEP Redirect Newlin Rebuttal Ex. 2, Tr. Ex. vol. 23. Anticipating the refinancing of low-cost debt the DEP must manage in the coming years – $1.3 billion over the term of the MYRP – potentially impacting DEP's credit quality, such that it might be frozen out of the market or have its borrowing costs significantly increase, is a risk that the Commission should not take. I am concerned that 9.8% takes this risk.

On the record and in light of the very real and complex challenges facing DEP in the coming years – including, to name a few, retirement and/or refinancing of debt in a higher interest rate environment, continued coal ash remediation efforts, construction of

MYRP projects, construction of other transmission and distribution system upgrades necessary to ensure reliability and facilitate the transition, retirement of existing generation, construction of new generation, restoration of system damage caused by extreme weather as a consequence of DEP's being a "storm prone service territory,"[2] fuel price volatility, and labor and materials price volatility – I am not persuaded that an ROE of 9.8%, even with a 53.0% equity layer, particularly given several of the other decisions in this proceeding, will give DEP the cushion it needs to remain consistently above its 21.0% FFO-to-debt downgrade threshold to protect against a downgrade. And, again, I am persuaded that a downgrade will cost customers. As DEP witness Newlin explained in response to cross-examination by the Public Staff, sequential drops in the (Moody's) rating translates to an additional cost to the utility to access capital – each drop can amount to additional incremental borrowing costs of 5-10 basis points but perhaps more given market conditions. Tr. vol 23, 23-24. DEP witness Newlin warns that while allowing DEP to recover less for its cost of equity capital may save customers in the short term, over time as debt matures and must be refinanced, such a measure will impose more cost on customers. *Id.* at 27. Moreover, I note that evidence in the record shows that Georgia Power Company has a credit rating of Baa1, which is two notches below DEP's current credit rating. *Id.* at 24. This lower credit rating results in a higher cost of equity capital of 10.5% for Georgia Power Company and, ultimately, its customers.

DEP witnesses also testified to cost-saving measures, O&M savings, undertaken by DEP since its last rate case. Specifically, DEP witness Abernathy testified:

> We did, you know, implement a series of routine cost-cutting measures to address not only COVID impacts, also mild weather, increased storm costs, things we do in normal course of business when faced with revenue pressures.

Tr. vol. 21, 1332.

While I expect DEP to find every efficiency in the provision of service to its customers and mitigate costs it incurs in providing service to the greatest extent practical, cost-cutting in the face of financial pressure, at a certain point, becomes a concern as it has the potential to impact the reliable operation of the electric system. Given the dynamics of the electric system, including changes in the generating mix, as well as the increasingly extreme summer and winter weather in North Carolina, now is not the time to put DEP in a position to cut to the extent that could impair the reliable operation of the system.

Based on the foregoing, I conclude that the Order's lack of enthusiasm for or lack of consideration of the largely unrebutted testimony of DEP witness Newlin as to credit quality and other evidence of record cited in this dissent is ill-founded. The decision to authorize an ROE of 9.8% has the very real potential to further stress DEP's credit

[2] *See* Moody's Credit Opinion for Duke Energy Progress, LLC, 2 (May 11, 2023); DEP Redirect Newlin Rebuttal Ex. 1, Tr. Ex. vol. 23.

metrics, which will cost customers. Given the real-world challenges that DEP must tackle in the coming years, unlike the majority, I am not willing to take that risk.

Fourth, I note that the Commission recently allowed an ROE of 9.8% for the two largest water and wastewater public utilities in North Carolina. Order Approving Partial Settlement Agreement and Stipulation, Deciding Contested Issues, Granting Partial Rate Increase, Approving Water and Sewer Investment Plan, and Requiring Customer Notice, *Application by Carolina Water Service, Inc. of North Carolina for Authority to Adjust and Increase Rates and Charges for Water and Sewer Utility Service in All Service Areas of North Carolina and Approval of a Three-Year Water and Sewer Investment Plan*, No. W-354, Sub 400 (Apr. 26, 2023); Order Approving Motion on Wastewater Rate Design and Approving Schedules of Rates, Schedules of Connection Fees, and Customer Notices, *Application by Aqua North Carolina, Inc. for Authority to Adjust and Increase Rates for Water and Sewer Utility Service in All Its Service Areas in North Carolina and for Approval of a Water and Sewer Investment Plan*, No. W-218, Sub 573 (July 31, 2023). DEP witness Morin testified that when viewing authorized returns on water utilities versus the authorized returns on vertically integrated electric utilities over a long time period, there is a difference typically on the order of 20 to 30 basis points lower for the water utilities. Tr. vol. 9, 32. My review of the record reveals that no party contested or otherwise rebutted this evidence. While I take no issue with and support the Commission's decisions in the recent CWSNC and Aqua cases, I note that at least in recent history, the trend for ROEs for the water/wastewater utilities and electric utilities has more or less mirrored that testified to by DEP witness Morin – until this Order. I must give this evidence some weight in forming my view that 9.8% is not an accurate reflection of DEP's cost of equity capital.

II. COVID Deferral

I dissent as to the Order's treatment of the deferred COVID-related costs. The Order: (1) approves DEP's recovery of the deferred COVID-related costs pertaining to customer fees waived, incremental bad debt expense, and employee safety; (2) reduces these allowed costs by certain COVID-related expense savings for employee travel expenses, printing and postage costs, DEP's filed ERCs, and the carrying cost benefit of the delayed payment of the employer portion of social security tax; (3) does not allow DEP to recover the carrying costs accrued during the deferral period or a return on the unamortized balance during the amortization period; and (4) requires that these costs be amortized over a six-year period.

The Order notes that approximately 90% of the deferred costs incurred are waived customer fees and incremental bad debt expense and concludes that these two costs resulted directly from governmental action, including mandates from the Commission. For this reason, the Order concludes that the costs associated with waived customer fees and incremental bad debt expense are appropriate for recovery from customers. With respect to employee safety costs, the Order concludes that these costs are appropriate for recovery from customers because to provide essential electric service, many of DEP's employees were not allowed the option to work from home and instead had to show up,

in person, at work, at power plants and other facilities, or to repair damage following storms. I agree with these conclusions.

The Order reduces the costs to be recovered by certain COVID-related expenses. I agree that the amount of deferred COVID-related costs should be offset by savings identified by DEP that were directly attributable to the pandemic, which include: (1) reduced employee expense related to reduction in or elimination of travel, and (2) reduced printing and postage costs as a result of the disconnect moratoriums ordered by the Commission. I do not agree with the Order that costs to be recovered should be offset by the carrying cost benefit related to the delayed payment of the employer portion of social security tax, as the benefit received by DEP was simply a temporary deferral from the government and was fully paid by December 31, 2022. Tr. vol. 21, 1291.

I would have allowed recovery of costs associated with remote work, employee stipends and call center costs because I am persuaded that these costs were incurred as a result of the pandemic and facilitated DEP's seamless, uninterrupted and undiminished provision of service to customers during the pandemic. I am persuaded that the call center costs should be recovered, primarily as a result of DEP witness Quick's testimony as to the efforts DEP went to during the pandemic to serve those customers in need who called in seeking assistance. *Id.* at 1276-77. I suspect and anticipate that these efforts are the foundation for a new approach, going forward, to reaching and serving customers in need that will have real, direct impacts on those customers' bills.

In addition, I would have allowed DEP to recover its carrying costs on the deferred balance during the deferral period as well as on the unamortized balance during the amortization period. Evidence in the record indicates that DEP had accrued carrying costs of $12 million on the total incremental deferred costs of $93 million as of March 17, 2023. *Id.* at 1280.

Finally, I would have allowed DEP to recover these costs over a three-year amortization period, coincident with its MYRP.

At the onset of the pandemic, DEP took immediate action to mitigate the hardship to customers and to ensure the continued provision of the essential electric service to all of its customers in North Carolina. Those actions included waiving all disconnections for customers who did not pay their electric bills and waiving customer late payment fees, return check charges, reconnection fees, and residential customers' electronic payment fees. As I see it, DEP took extraordinary action to provide customer support though efforts initiated on its own, ordered by the Commission, and/or resulting from State of Emergency executive orders. Customers were served, even when unable to pay, and DEP carried those balances for customers for many months, now years, in some cases. This provision of service enabled its customers to work from home, attend school from home, and otherwise remain in the home minimizing risk to others. As the AGO pointed out,

> The health and safety of communities are affected by the efforts of all residents to stay home and socially distance to slow the spread of the

coronavirus. Accordingly, entire communities benefit from efforts to keep electric service turned on in households that are struggling.

Reply Comments of the Attorney General's Office, *Joint Petition of Duke Energy Carolinas, LLC, and Duke Energy Progress, LLC, for Approval of Accounting Order to Defer Incremental Expenses as a Result of COVID-19*, Nos. E-2, Sub 1258, E-7, Sub 1241 (Nov. 30, 2020).

I agree strongly with the AGO that DEP's actions during the pandemic benefitted all customers, not just those who were unable to pay. In addition, DEP's provision of service during the pandemic and disconnect moratorium periods, without the ability to disconnect for non-payment and with the obligation to enter into longer-term payment arrangements, goes to the heart of the regulatory compact.

In my view, the regulatory compact can be framed as follows. In exchange for an exclusive service area sanctioned by the State, the utility accepts an obligation to serve all customers within that service area, subject to regulatory oversight. Additionally, in return for agreeing to commit the necessary capital for the provision of service, the utility must be given the opportunity to earn a fair and reasonable return on that capital. *See generally*, Charles F. Phillips, Jr., The Regulation of Public Utilities, 21, 3d ed. (1993).

I conclude that the record in this proceeding demonstrates that DEP met its obligation under the regulatory compact. It served customers throughout the pandemic-related moratorium period, regardless of whether those customers paid. It had to carry the amounts owed by the customers who could not pay throughout the moratorium, during a period of time when, as the record demonstrates, DEP faced revenue pressures. Tr. vol. 21, 1332. And, DEP was directed by this Commission to enroll automatically customers who had been unable to pay into extended repayment plans. The late fee moratorium, which I view as an incentive for the payment of bills and which was in effect by order of this Commission, was not lifted until September 2022 coincident with the lifting of the State of Emergency declaration related to the pandemic.

Thus, the actions of this Commission obligated DEP: (1) to provide service even to those customers that were not able to pay their bills: (2) to cease to use its approved tools that are incentives for bill payment for a prolonged period of time; and (3) to enter into extended payment plans with customers. The record reflects that DEP complied with the orders of this Commission. No party to this proceeding took issue with DEP's provision of service during this period of time or with the prudency of the costs incurred by DEP to this end. While the Order reflects a balancing of equities to arrive at the final decision, I do not agree with the balance struck. Customers who were unable to pay benefitted during the pandemic and during the extended period of time for repayment of any amounts owed to DEP. All customers benefitted as DEP's actions allowed households in need to continue to have service in their homes during a time when remaining at home was essential to the health and well-being of all. Denying DEP an opportunity to recover all of its costs does not recognize the value that DEP provided to all of its customers. In addition, I note that the denial of the carrying costs is roughly equivalent to 10 basis points, perhaps more. Thus, I am

concerned that this decision compounds the majority's decision to authorize an ROE of 9.8% and that it will erode DEP's financial health, to the detriment of all customers.

The public health situation presented by the pandemic was an unforeseen, unimaginable crisis that impacted the lives of all North Carolinians in many, difficult and, often heart-breaking ways. DEP's efforts to continue the provision of service to all customers during this time and to provide assistance to those who were unable to pay were critical to the health and general well-being of North Carolina. Tr. vol. 21, 1273-74. In my view, aptly captured by the Attorney General's Office, DEP provided service that benefitted all North Carolinians. I do not believe it is appropriate to deny DEP an opportunity to recover all of its costs, including its carrying costs. This Commission ordered DEP to take action, which included carrying costs for customers who could not pay. DEP upheld its obligations under the regulatory compact. This Commission should have done the same.

III. Affordability – Next Steps

As explained in the Order, DEP requested approval of a CAP and two new tariffs, the CAP Rider and the CAR Rider. DEP witness Harris testified that the CAP proposal, initially developed in the LIAC docket, is designed to assist low-income customers who are facing affordability challenges. Under the CAP, eligible customers would automatically receive a $42.00 monthly bill credit for a 12-month period. Customers who are eligible for and receive funds from either the Low Income Energy Assistance Program (LIEAP) or the Crisis Intervention Program (CIP) would qualify for assistance under the CAP. DEP would automatically enroll eligible customers into CAP using a list of customers provided by the North Carolina Department of Health and Human Services (DHHS). The Order also explains that in addition to the $42.00 bill credit on their next 12 monthly bills, DEP will refer CAP customers to other income-qualified weatherization and energy efficiency services that can assist customers with reducing energy usage.

Public Staff witness D. Williamson testified that the concept of the CAP emanated in the LIAC stakeholder meetings, during which a diverse group of stakeholders met over the course of a year to discuss affordability challenges being experienced by low-income customers to propose ways to address those challenges. He testified that one particular proposal (Proposal 24) contained within the LIAC Final Report combined proposals submitted by the NCJC and by Duke and that Proposal 24 received broad support among the LIAC stakeholders. He testified that DEP estimated 60,000 eligible customers would participate and developed its costs associated with the program based on that estimate. Public Staff witness D. Williamson testified regarding the Public Staff's concerns with the cross-subsidization issues created by the CAP, tr. vol. 20, 144, as well as the Public Staff's preference that there be a clear legislative directive for the development and deployment of assistance programs like the CAP. *Id.* at 146. Ultimately, the Public Staff recommend approval of the CAP for a three-year pilot term, running concurrently with the MYRP, on the basis of the uncertainty of CAP-related costs resulting from the unknown number of potential recipients and the potential for the CAP to be more impactful to non-participating customers than anticipated. He also testified as to concern that once an

affordability program is initiated, it would be difficult to end the program regardless of the costs, benefits, or impacts on CAP recipients and non-participating customers. He testified that the three-year pilot period would provide the Commission with an opportunity to evaluate the performance of the CAP. *Id.* at 147.

Sierra Club witness Howat endorsed and advocated for the reporting of certain data at a zip code level primarily to inform program design and targeting of effective energy efficiency and other affordable energy programming. Tr. vol. 18, 201-02. He advocates that the CAP bill credit be tiered based on zip code level data. *Id.* at 219.

As the Order points out, DEP took issue with the recommendation related to the disclosure of zip code level data. Specifically, DEP witness Barnes testified that DEP opposed the sharing of non-public customer information data aggregated at a zip-code level, noting that DEP's Code of Conduct, approved by the Commission in its Order Approving Merger Subject to Regulatory Conditions and Code of Conduct, *Application of Duke Energy Corporation and Piedmont Natural Gas, Inc., to Engage in a Business Combination Transaction and Address Regulatory Conditions and Code of Conduct*, Nos. E-2, Sub 1095, E-7, Sub 1100, and G-9, Sub 682 (Sept. 16, 2016), prohibits the disclosure of aggregated non-public customer data. Tr. vol. 22, 87.

The Order notes that on May 4, 2023, DEP, DEC, Sierra Club, NCJC, et al., and the Public Staff filed the Affordability Stipulation, pursuant to which DEP agreed to withdraw the Low-Income/Affordability PIM it had initially proposed and instead would ensure that a shareholder contribution of $16 million to benefit income-eligible customers would be made as follows: $10 million in support of health and safety repairs that would allow for energy efficiency and weatherization upgrades to homes; and $6 million for the Share the Light Fund, which offers customers bill payment assistance. In addition, DEP agreed to implement the CAP as a three-year pilot, on the Public Staff's recommendation, and to convene a stakeholder engagement process to consider CAP data, metrics, and future CAP program features. The Order also notes that the Affordability Stipulation provides that parties agree to explore "a tiered customer assistance program based on income levels if that feature can be incorporated into the design of the CAP."

The Order approves the Affordability Stipulation but, problematically in my opinion, directs DEP to take action beyond that required by the Affordability Stipulation. Specifically, in a section entitled Affordability – Next Steps, the Order directs DEP to convene a stakeholder group which includes the stipulating parties to the Affordability Stipulation within 90 days of issuance and to invite members of the LIAC to join that stakeholder group. The Order further directs that the group meet quarterly and file a report within six months on the data and information that is to be reported to the Commission annually during each of the three years of the CAP pilot. The Order also directs the stakeholder group to develop a tiered program and directs DEP to file a report relating to the feasibility and proposed structure of a program the later of (i) 18 months after the entry of the order in this proceeding, or (ii) when there is one year of data from the CAP.

As a general matter, I note that the Affordability Stipulation represents the give and take of the parties and that the terms and conditions of the stipulation reflect the compromise each was willing to make, as well as resolution of issues disputed in this proceeding. Among the disputed issues was the term of the CAP, which the Public Staff advocated should be limited, at least initially, to a three-year term in order to provide the Commission with an opportunity to examine the impacts of the program. Whether the CAP should be tiered was also disputed, as the Sierra Club advocated that DEP's proposal for a flat credit be modified to a tiered credit. In addition, the disclosure of zip code level data was a contested issue in this proceeding, with the Sierra Club's advocating that all data be reported at the zip code level and with DEP's opposing that recommendation. Going farther than the settlement of issues between the parties to the Affordability Stipulation upsets the balance the parties struck in the resolution of disputed issues and deprives the Public Staff, and the Commission, of the years of data the Public Staff anticipated would be necessary to make meaningful examination of the CAP before having to design a tiered program.

In addition, well beyond the scope of work envisioned in the Affordability Stipulation, the Order directs that the annual report shall include certain data points at the zip code level and directs that DEP report, on a semi-annual basis, certain data regarding health and safety repairs that are made with shareholder funds, again at the zip code level.

While the Order requires DEP to seek from the Commission any waivers necessary to comply with the Order, it is not clear, based on what the Order requires, whether the Code of Conduct and policies underlying the specific provisions of the Code of Conduct will receive the examination they deserve in any such waiver proceeding. In addition, the Order provides DEP no additional funding for the additional work it directs. The majority directs the collection and reporting of this data, as well as the additional time and effort in a quarterly stakeholder process, without any evidence of record indicating what such effort will cost.

Section III of DEP's Code of Conduct prohibits the disclosure of any "Customer Information" without customer consent, and the Commission has determined in a previous decision that the Code does not even allow for the release of aggregated data except as allowed by the Commission. Order Approving Limited Waiver of Code of Conduct, *Application of Duke Energy Carolinas, LLC, for a Waiver of Code of Conduct Section III A. 2(b) and (f)*, No. E-7, Sub 997 (Feb. 29, 2012). Customer Information is defined, in Section I of the Code, as "Non-public information or data specific to a Customer or a group of Customers, including, but not limited to, electricity consumption, natural gas consumption, load profile, billing history, or credit history that is or has been obtained or compiled by DEC, DEP, or Piedmont in connection with the supplying of Electric Services or Natural Gas Services to that Customer or group of Customers." The fact that a customer has been late, is on a payment plan, or is on a particular rate tariff, including enrollment in CAP and the bills for those CAP customers, seem to fall within the definition of Customer Information.

On this record, which is underdeveloped, I cannot agree with the requirement that DEP disclose to the stakeholder group and report to the Commission the zip code level data required by the Order. There is no evidence in the record as to why the Code of Conduct prohibits the disclosure of this type of information or the policy served by the prohibition. There is no evidence in the record as to why this specific information is necessary for understanding the efficacy and impacts of the CAP pilot. In addition, before directing this type of action, I must be persuaded that customers whose data are being collected and shared, or the communities in which they live, will not be inadvertently harmed by such action. Specifically, I would want to be certain that there is no opportunity, once disclosed to stakeholders or otherwise made public, for such data to be used against a customer in a way that might increase affordability challenges for that customer. I recognize that the data will be anonymous and it may be that collecting and disclosing zip code level data poses no risk in this regard, but the record is not developed on these issues, in particular risks to the customers that the majority is trying to serve. Because I agree that the Code of Conduct adopted by the Commission deserves more respect than that shown by the Order, I would not have imposed additional obligation on DEP.

Finally, I agree with the Public Staff that addressing affordability for the most vulnerable customers is, and must continue to be, a critical focus of the utility and the Commission. However, given the concerns expressed by the Public Staff, as well as by CIGFUR witness Phillips, regarding cross-subsidization, the reduction of customer usage through energy efficiency – actually reducing the amount of electricity that a customer must use and pay for – better serves customers. While I support the give and the take, as well as the outcome, of the Affordability Stipulation, I would not have gone beyond the stipulation, as the majority does, for this reason. In my view, DEP and its stakeholders' resources and efforts are well-spent identifying and developing programs that maximize the deployment of federal funding available for weatherization and energy efficiency, particularly funding that results from recent federal legislation, to the advantage of those customers in need. I see DEP's Residential Income-Qualified Energy Efficiency and Weatherization Program, Order Approving Program, *Application by Duke Energy Progress, Inc. for Approval of Residential Income-Qualified Energy Efficiency and Weatherization Program*, No. E-2, Sub 1299 (Mar. 1, 2023), as the type of program that better addresses energy burden and intensity. I also see the availability of federal dollars available for weatherization as a significant and real opportunity to expand the reach of this program to customers in need and to provide longer term assistance to these customers. My hope is that DEP's resources and attention remain on this program and on the opportunity for its customers created by the availability of the federal funding.

/s/ Charlotte A. Mitchell
Chair Charlotte A. Mitchell

DOCKET NO. E-2, SUB 1300

Commissioner Daniel G. Clodfelter, concurring in part and dissenting in part:

I am in agreement with the Commission's Order in all respects save one, and as to that lone issue I dissent. With respect to all other matters I concur, but I write separately to elaborate two points, one concerning performance incentive measures and the second relating to recovery of rate case expense associated with DEP's prior general rate case, the 2019 Rate Case. I address first the issue as to which I dissent.

I. Revenue Decoupling and Electric Vehicles

It is all very well that DEP's proposal for estimating revenues derived from residential electric vehicle (EV) charging would potentially support and encourage increased adoption of EVs by residential customers.[1] But first, before that worthy objective can be considered, the proposal must fit within the actual language of N.C.G.S. § 62-133.16(c)(2). It does not do so, based on a plain reading of the statute. The statute requires that EV revenues eligible for exclusion from the residential revenue decoupling mechanism are those derived from DEP's EV-specific riders or tariffs, not revenues that are derived from some method of estimation, however reasonable the process of estimation may be. The arguments on this point – and the defects in DEP's methodology for estimation even if estimation were proper in the first place – are well developed in the AGO Post-Hearing Brief at 9-18, and I adopt them here.[2]

II. Performance Incentive Measures

On the matter of performance incentive mechanisms (PIMs), N.C.G.S. § 62-133.16 is not especially demanding, requiring only that "one or more" PIMs be included in a rate application under that section. Even by that modest standard, I find the PIMs offered up pursuant to the PIMs Stipulation underwhelming.[3] Largely if not entirely based on the proposed reliability PIM, however, I am willing to accept that DEP's Application complies with the minimum requirements of the statute.[4] The reliability PIM establishes a target that

[1] AGO witness Nelson challenged whether this claimed linkage actually holds, but for the present I am willing to accept the claim.

[2] I acknowledge that in the PIMs Stipulation DEP agrees to work with the Public Staff and file within 90 days "EV tariffs and/or programs to estimate and update" revenues from EV charging. I do not consider this "and/or" commitment to be sufficient. After DEP has filed and has received approval for specific tariffs for residential EV charging, the decoupling mechanism can be revisited and modified as appropriate.

[3] I will not discuss the PIMs presented in DEP's original rate application since they are no longer before the Commission, except to say that I found the analysis and critique of those proposals by Public Staff witnesses Thomas and D. Williamson, by AGO witness Nelson, by CIGFUR witness Gorman, and by NCJC, et al. witness Posner to be highly persuasive.

[4] I am content to accept, for this first round of ratemaking under the new paradigm, the revised Time Differentiated and Dynamic Rate Enrollment PIM and the Renewables Integration and Encouragement PIM as they are set forth in the PIMs Stipulation, though I do not place much weight on them. I agree with several of the non-stipulating intervenors that those PIMs are not especially well-designed and that they address matters that likely do not require the "push or pull" of a PIM incentive to move the issue forward. Directives and initiatives

responds to the policy goals set forth in N.C.G.S. § 62-133.16(d)(2)(j) and likely also (d)(2)(i); it is well-defined and objectively measurable; and it is primarily, though not solely, under DEP's control. These are all necessary elements for a PIM pursuant to N.C.G.S. § 62-133.16(c)(3).

Though the requirement that it do so is not expressly spelled out in the enabling statute, the reliability PIM is also well-integrated with the other elements of DEP's MYRP application. It will provide some evidence, albeit indirect, of the success of DEP's proposed MYRP investments in transmission and distribution infrastructure over the period of the MYRP. Since these investments lie at the core of the MYRP, it is especially valuable that at least one of the proposed PIMs is linked to that core. Given the new ratemaking environment created by the multi-year ratemaking structure, with the many attendant and new forms of risk and reward for both DEP and ratepayers, I would have preferred to be grappling with PIMs that more directly spoke to the challenges that new ratemaking environment presents. For example, PIMs that would reward DEP for realizing reductions in operating costs and expenses, in order to balance the upward pressure on rates from year-to-year, or PIMs that would incentivize DEP to deliver the capital projects identified and included in the MYRP investment plan on time or under budget, in order to protect against the risk that revenues would have been earned on projects never completed, or delayed, or cancelled due to cost, could have more closely aligned the risks and rewards of the PIMs themselves with the potential risks and rewards of the MYRP.[5]

I do not fault DEP that this did not happen. With no prior history in designing and structuring PIMs and with little specific direction from the statute or from the Commission's rule about how to do so, DEP understandably defaulted to measures that were readily at hand and could be set up and proposed without great effort. Nor do I fault the Commission for not providing, in Rule R1-17B, more explicit guidance for DEP with respect to such things as the preferred or desired policy goals for PIMs and the methods for structuring PIMs to best achieve those goals. The Commission was given the task of implementing the new ratemaking paradigm established by the PBR Statute on a short timetable that simply did not permit an extended process of analysis, review, and stakeholder involvement on such matters. One thing that has been apparent from conversations with commissioners in other jurisdictions, from academic literature on the topic, from presentations on the topic of performance-based ratemaking at conferences, and from the work of the NERP task forces in North Carolina is that successful implementation of a robust system of performance-based incentives requires considerably more time and more stakeholder involvement than was available in the present circumstance. Put

---

stemming from the Carbon Plan, the recently approved revised residential NEM tariff, and the revised non-residential NEM tariff approved in this case are likely to provide more than sufficient incentives for interconnection of new renewable resources, for expanded adoption of net metering, and for migration to time-differentiated rate structures. As several intervenors also note, the financial rewards proposed for these PIMs are modest, far less individually and collectively than the statutory cap, and are therefore unlikely to drive any significantly different behavior by the utility than what would otherwise occur without the PIMs.

[5] The reporting requirements set forth in Rule R1-17B(h)(2) and (3) do permit tracking of performance relative to capital projects included in the MYRP, including such matters as project substitutions, delays, and costs relative to projections, but they lack the incentive element that would have been provided by a PIM.

another way, the development of a sound policy and regulatory basis for PIMs – most especially the process for prioritizing and selecting goals for PIMS that are supportive of and integrate well into the larger framework of regulatory policy initiatives – is just not something that could be done in a hurry. In the present instance DEP, the various intervenors and interested parties, and the Commission have done the best that could be done in the time that has been available.

First time attempts to tackle any new challenge – or to take up an old challenge in a new way – may prove rocky and will most likely produce surprises and disappointments. This first MYRP rate case effort has not proved otherwise. What is most important now is that we build upon this experience and spend the time we collectively have between now and when DEP's next MYRP rate case is expected to be filed working to build out a more robust structure for selecting, developing, evaluating, and implementing PIMs. In particular, I believe it would be valuable for DEP and interested stakeholders to engage in a deeper discussion concerning the priority among the various optional policy goals set forth in N.C.G.S. § 62-133.16(d)(2) in order to ensure that the PIMs incorporated into an MYRP reinforce and build upon the policies embodied in the Carbon Plan and in related regulatory initiatives. To this end, I believe the Commission should revisit the recommendations made by the Public Staff and by a number of other intervenors in the original rulemaking docket that the Commission initiate a more extended and in-depth proceeding to put more "flesh on the bones" of the statute and of existing Rule R1-17B.[6] As we noted in our Order adopting Rule R1-17B, "the Commission may choose to initiate dockets to set policy goals for PBRs if it determined in the future that such dockets would be useful."[7] This is our opportunity to build out a more meaningful platform to enable DEP and its ratepayers to benefit from the potential contained in the performance-based ratemaking elements in the PBR Statute. We need to take that opportunity while we have time to do so and before the next MYRP is upon us.

III. Recovery of Additional Rate Case Expense Associated with 2019 Rate Case

The Commission has allowed recovery through the rates established in this case of certain additional rate case expenses associated with and arising out of DEP's prior

[6] E.g., Initial Comments and Proposed Rule of the Public Staff, Rulemaking Proceeding to Implement Performance-Based Regulation of Electric Utilities, No. E-100, Sub 178 (Nov. 9, 2021); AGO Reply Comments, Rulemaking Proceeding to Implement Performance-Based Regulation of Electric Utilities, No. E-100, Sub 178 (Dec. 17, 2021); Comments and Partial Proposed Rules Submitted on Behalf of North Carolina Justice Center et al., Rulemaking Proceeding to Implement Performance-Based Regulation of Electric Utilities, No. E-100, Sub 178 (Nov. 21, 2021); Reply Comments of CIGFUR I, II and III, Rulemaking Proceeding to Implement Performance-Based Regulation of Electric Utilities, No. E-100, Sub 178 (Dec. 17, 2021). The position taken by these parties is also supported by the PBR Regulatory Guidance document issued by the NERP working group, which noted the process of developing, monitoring, and evaluating PIMs is best considered an "iterative" process. See PBR Regulatory Guidance - Implementation Suggestions for the NCUC from the North Carolina Regulatory Process at 19 (Dec. 22, 2020).

[7] Order Adopting Rule, Rulemaking Proceeding to Implement Performance-Based Regulation of Electric Utilities, No. E-100, Sub 178, at 14 (Feb. 10, 2023).

general rate case, (2019 Rate Case).[8] It has done so over the strong objection of the Public Staff, and it has acknowledged the justice of the Public Staff's position. But for one overriding factor, I would be inclined to deny recovery of the additional 2019 Rate Case expense for the reasons well stated by the Public Staff.

At the time of the Second Agreement and Partial Stipulation of Settlement between DEP and the Public Staff on July 31, 2020, DEP already knew that due to the Covid-19 pandemic the hearing of its 2019 Rate Case would be conducted under considerably different circumstances than were customary – that the hearing would be conducted remotely, that portions of the hearing would be consolidated with the hearing of common issues in the then-pending general rate case involving DEC, and that there would likely be delay in hearing those portions of the case that were specific only to DEP. In addition, DEP knew at that time that the Commission's Order in the 2017 Rate Case was on appeal and that there was a risk that order would be reversed in whole or in part and remanded for further proceedings. In its negotiations with the Public Staff, DEP could have taken steps to protect itself from these "known unknowns" affecting rate case expenses, but it did not do so.

The Supreme Court's action to remand to the Commission for further proceedings the order in the 2017 Rate Case came after the close of evidence in the 2019 Rate Case and after the parties had submitted their post-hearing briefs and proposed orders. One possible result of that remand could have been extended re-litigation of issues from the 2017 Rate Case and, even quite possibly, re-opening of the record in the 2019 Rate Case to permit the parties to offer additional evidence or argument concerning the effect of the Supreme Court's ruling on coal ash cost recovery issues in the 2019 Rate Case. In the end, DEP, the Public Staff, the AGO, and others were able to resolve the issues arising from the remand of the 2017 Rate Case in a settlement agreement that was comprehensive in nature and eliminated the risk of prolonged and expense continuing litigation. I consider the result obtained by this resolution to be far less costly for ratepayers in both the short term and in the long run than that alternative. For that reason, and that reason alone, I concur in the Commission's disposition of the issue of supplemental rate case expense associated with the 2019 Rate Case. As does the Commission in its Order, I find the circumstances to be unusual and wish to emphasize that I do not consider this disposition to be precedential for future cases.

/s/ Daniel G. Clodfelter
Commissioner Daniel G. Clodfelter

[8] Strictly, a good portion of these additional expenses can also be said to relate to DEP's next previous general rate case, the 2017 Rate Case, since they were incurred as a result of the Supreme Court's partial reversal and remand of the Commission's Order in the 2017 Rate Case.

STATE OF NEW YORK
PUBLIC SERVICE COMMISSION

At a session of the Public Service Commission held in the City of Albany on May 19, 2021

COMMISSIONERS PRESENT:

John B. Howard, Interim Chair
Diane X. Burman, concurring
James S. Alesi
Tracey A. Edwards

CASE 20-G-0101 - Proceeding on Motion of the Commission as to the Rates, Charges, Rules and Regulations of Corning Natural Gas Corporation for Gas Service.

Case 16-G-0204 - Petition of Corning Natural Gas Corporation to Defer Leak Survey and Repair Costs Over and Above the Level Last Established in Rates.

ORDER ESTABLISHING RATES AND RATE PLAN

(Issued and Effective May 19, 2021)

BY THE COMMISSION:

I. INTRODUCTION

In this Order we establish rates and a rate plan for Corning Natural Gas Corporation ("Corning" or "the Company"). In lieu of the one-year revenue increase of $6,256,000 requested by the Company, we determine that a base rate reduction of $766,000 is required. The revenue requirement supporting the $766,000 decrease is detailed in Appendix 2. In addition to the base rate decrease, a $1.3 million tax surcredit is expiring and the Delivery Rate Adjustment ("DRA") surcharge is forecast to be reduced by $30,000. Including the impact of the expiration of the surcredit and change to the DRA, the total net revenue

impact on ratepayers will be an annual increase of $505,000. The overall revenue increase is 1.77% over the twelve-month period ending January 31, 2022 (“Rate Year”). The average annual bill impact on residential customers during the Rate Year will be an increase of approximately 2.43%. We are also improving the Company’s low-income program. Due to these improvements qualifying low income customers will see an annual bill decrease of approximately 6.14%.

In this Order we also continue a number of positive and negative incentive mechanisms and direct a number of measures to ensure that the Company continues its leak-prone pipe replacement program at its current level, increases its efforts to reduce its leak backlog, minimizes excavation damage to its facilities, maintains its current targets for fast response times in emergencies, fully complies with pipeline safety regulations, increases its work to repair minor leaks in a flood-prone area, improves its coordination with and training of other emergency responders, and establishes a pilot program for residential methane detectors. We also continue and improve the Company’s customer service metrics and programs to minimize complaints, achieve good results on customer satisfaction surveys, and minimize missed appointments, uncollectibles and terminations. We also direct an improvement to the Company’s outreach and education plan, approve a proposal by Staff (accepted by the Company) to eliminate fees for credit and debit card payments, and approve a proposal by Staff (also accepted by the Company) to file a plan for electronic Deferred Payment Agreements.

II. PROCEDURAL BACKGROUND

On February 27, 2020, Corning filed with the New York Public Service Commission (the “Commission”) revised tariff

leaves with an effective date of April 1, 2020 (the "Rate Filing"). Using as a base period the 12 months ended September 30, 2019 (the "Historic Test Year"), the revised tariff leaves would result in an increase in revenues from the Company's gas operations of $6,255,926 in the Rate Year. The Company proposed a three-year rate plan encompassing the initial Rate Year and the two succeeding rate years (the 12-month periods ending January 31, 2023, and 2024), with rate increases of $845,142 and $680,913, respectively. The Company asserted that three years of stand-alone rate increases would impact customers' total bills by 23.4%, 2.56% and 2.01%, respectively. Corning proposed that these increases be levelized over three years, which it asserts would result in an increase of $3,523,167 in each Rate Year, with a total bill impact of 10.93% in each Rate Year.

In the Rate Filing, Corning indicated its openness to developing a staged increase proposal for the 12 month periods ending January 31, 2025, and January 31, 2026. Under the staged increase approach, the Company would recover the carrying costs on incremental plant additions over the previous year. As an alternative to the staged increase, Corning suggested a construction surcharge mechanism ("CSM") that would permit the Company to establish a surcharge factor to be applied to all delivery customers, except those with contractually determined prices, that would permit the Company to cover the carrying costs on projected infrastructure investments.

The Rate Filing included prepared testimony and exhibits constituting Corning's direct case. In Attachment B to the transmittal letter for the Rate Filing, Corning summarized the major drivers behind the proposed rate increases. Of the $6,255,926 Rate Year increase, the costs of mandated initiatives comprise $4,535,731. Of that total, $3,122,469 was in response to legislation enacted by the State of New York, including in

particular the Climate Leadership and Community Protection Act (the "CLCPA"). Corning's filing asserted that such accelerated depreciation is necessary because the CLCPA will shorten the effective life of the Company's existing and future investment in infrastructure. The $3,122,469 increase in revenue requirement from the proposed accelerated depreciation is the largest single issue in this case, amounting to nearly half of the proposed one-year rate increase.

This proceeding was commenced upon the Commission's receipt of the Rate Filing and two Administrative Law Judges (ALJs) were appointed to preside over this case. Procedural and technical conferences were held remotely on April 14, 2020. On April 24, 2020, the ALJs issued a Ruling on Procedure and Schedule, establishing dates for the filing of Company updates, direct testimony of Department of Public Service trial Staff ("Staff") and intervenor parties, rebuttal testimony, and the commencement of evidentiary hearings.

On April 16, 2020, the Company filed Supplemental Direct Testimony, and an exhibit, providing an update on financial market conditions and the effect of those conditions on risk perceived by equity investors. On May 12, 2020, Corning filed updates and corrections to the Rate Filing, consisting of additional direct testimony and revisions to certain exhibits.

On June 26, 2020, Staff and Multiple Intervenors ("MI") filed direct testimony and exhibits, and an individual intervenor-party, Bob Wyman, filed direct testimony. On July 14, 2020, the New York Geothermal Energy Organization ("NY-GEO") filed comments opposing Staff's rejection of Corning's proposal to shorten depreciation service lives. On July 24, 2020, the Natural Resources Defense Council ("NRDC") and the Sierra Club filed joint comments voicing similar opposition to Staff's position. On July 24, 2020, Corning filed

rebuttal testimony and exhibits and Mr. Wyman filed rebuttal testimony. Corning filed supplemental rebuttal testimony on July 30, 2020.

By letter dated August 4, 2020, Corning provided notice of impending settlement negotiations to the Secretary, the ALJs, and the parties in this case. By separate correspondence dated August 7, 2020, Corning set August 21, 2020, as the date for the commencement of settlement negotiations.

On August 10, 2020, the ALJs held a prehearing procedural conference. On August 12, 2020, the Examiners issued a Ruling on Schedule and Procedure, which, among other things, cancelled the evidentiary hearings previously scheduled to commence on August 17, 2020, and required biweekly reports on the status of the settlement negotiations.

The Commission next scheduled information sessions and public statement hearings, which were subsequently held remotely on September 22, 2020. Corning presented its settlement offer at the August 21, 2020 settlement conference. It was anticipated that a Staff counter-offer would be presented at a subsequent settlement conference. Corning provided the ALJs with biweekly reports from September until early March 2021. To accommodate the potential for a settlement, Corning, by letter dated November 20, 2020, agreed to an extension of the statutory suspension period from January 29, 2021, to June 1, 2021 conditioned upon a “make-whole” provision to keep customers and the Company in the same position as they would have been absent the extension. On January 22, 2021, the Commission granted the extension through May 31, 2021.

The ALJs required Corning to provide notice, by March 17, 2021, whether it would request a further extension of the suspension period to continue pursuing settlement. Corning

decided not to request a further extension of the suspension period and notified the ALJs of its decision on March 18, 2021. The ALJs held a prehearing conference on March 19, 2021, and presided over an evidentiary hearing on March 23, 2021. The resulting record consists of 1,259 pages of stenographic minutes and 55 exhibits. At the conclusion of the evidentiary hearing, the ALJs established a briefing schedule, with initial briefs due on April 16, 2021, and reply briefs due on April 23, 2021.

Initial briefs were filed by Corning, Staff, MI, Public Utility Law Project ("PULP"), Utility Intervention Unit ("UIU") and Mr. Wyman. Reply briefs were filed by Corning, Staff, and Mr. Wyman.

On April 29, 2021, Corning filed a letter purporting to address certain aspects of Staff's Reply brief. In response, DPS Staff, PULP, and UIU filed letters asking that Corning's letter be wholly disregarded because the ALJs had not authorized sur-replies and any consideration of the substantive arguments advanced by Corning in its filing would prejudice the other parties. We agree that Corning's letter failed to comply with the Commission's procedural regulations regarding sur-replies and thus will not consider it in this Order.

On May 5, 2021, Corning filed another letter, asking the Commission to take administrative notice of the Governor's recent announcement regarding the accelerated reopening of the New York State economy. We will disregard the request for administrative notice in the May 5 letter as an additional unauthorized sur-reply. In that letter, Corning also provided additional information regarding the status of the collective bargaining agreement between the Company and its employees, and the Company's position on wage increases.

On May 6, 2021, Corning filed a letter stating that the union membership voted on May 5, 2021, to ratify the terms

of the collective bargaining agreement. We have routinely recognized the completion of collective bargaining agreements prior to our decision in a rate case, and as discussed below we will do so here.

III. PUBLIC NOTICE

A notice pursuant to the State Administrative Procedure Act was published in State Register on October 14, 2020.[1] Four comments were filed on the page maintained for this case in the Document and Matter Management System. Three of those comments were filed by residential customers of Corning, while one comment was filed by a developer that undertakes business in Corning's service area.

All four comments expressed opposition to the proposed rate increase. One commenter described the Company's proposed rate increase as clever but bad for customers because it is too large. Commenters also asserted the Commission should not allow accelerated depreciation because the costs of climate change should not be borne entirely by ratepayers. They argued the rate impacts are too great, especially for customers on fixed incomes. Commenters argued it is an especially bad time for an increase in rates because of the adverse economic impacts of the COVID-19 pandemic. They argued that even in good times residents and businesses have trouble paying increased gas rates and pointed out that half the population of Corning's service territory is below the poverty line. Commenters also noted the fact that Corning laid-off or furloughed 700 workers due to the pandemic and that those families are still struggling. Commenters argued that the Company's requested return on equity of 10.2 percent is too high, especially since customers cannot

[1] SAPA No. 41-20-00011-P.

afford a significant rate increase at this time. Commenters pointed out that, while the Company cannot at present terminate service for non-payment, customer arrearages are up because of the pandemic and the full extent of the pandemic's impacts will only be realized when the Company can again begin terminating service for nonpayment. Commenters also claim that Corning can take other measures to cut its costs without raising rates so much. Finally, the developer-commenter stated that natural gas is quickly becoming an energy source of the past and that any additional investments in gas infrastructure will lead to stranded assets.

On September 4, 2020, the Secretary issued a notice of public statement hearings to be held, virtually, on September 22, 2020. Two public statement hearings were held on September 22, 2020, at 1 p.m. and 6 p.m. Four speakers made statements. The Town of Bath opposed the rate increase, describing the Company's proposals for return on equity and depreciation as aggressive and insensitive. The Town expressed concerns about meter accuracy and non-redundant plant serving the Town. The three remaining speakers supported the Company's proposal to depreciate all of the Company's assets within 30 years, both to avoid stranded investments and to promote the transition to the use of renewable energy. One speaker categorically objected to any new gas infrastructure investments by the Company.

IV. RATEMAKING ISSUES

A. COVID-Related Austerity Adjustments

Corning filed its rate case on February 27, 2020, prior to any understanding of the extent, if any, that the COVID-19 epidemic would result in financial impacts to Company's customers. Corning initially sought a Rate Year revenue requirement increase of more than 23%, or over $6.25 million.

In its May 12, 2020 update, Corning still sought a revenue requirement increase of over $6.22 million.

Corning claims that its proposed Rate Year revenue requirement reflects the Company's costs of implementing the Commission's policies and goals related to the CLCPA and its efforts to reduce greenhouse gasses, particularly with regards to the accelerated depreciation of its plant. Staff challenges the increase sought by Corning, arguing that such significant revenue requirement increases are almost unheard of, even during periods of economic prosperity.[2] Staff further argues that the Company's filings were ill-conceived in light of the tremendous revenue and rate impacts during the COVID-19 pandemic. Staff asserts that the impacts of the COVID-19 pandemic are unprecedented both in our lifetimes and in the history of the Public Service Commission.

In testimony Staff recommended a Rate Year revenue requirement increase of $270,773.[3] In its brief, however, Staff recommended four additional adjustments, totaling $47,218, and recommended a Rate Year revenue requirement of $223,555.[4] In recognition that Corning's rate plan was filed prior to any understanding of the economic ramifications of the COVID-19 pandemic, Staff also noted that the Commission may make additional discretionary reductions to the increase in the revenue requirement, if the Commission decides the economic climate faced by Corning's customers warrants further reductions. Staff identified four policy-based austerity adjustments that could be made: 1) modifying the amortization periods for regulatory assets and liabilities; 2) removing the

[2] Staff Initial Brief at 3.

[3] Staff Initial Brief at 1-2.

[4] Staff Initial Brief at 1-2.

allowance for management wage increases in the Rate Year; 3) removing the allowance for certain proposed new employees; and 4) removing the accelerated amortization of leak prone pipe ("LPP"). Staff noted that, although these adjustments were not specifically addressed during the evidentiary hearing, the Commission may nevertheless address them in this Order given that they are based on underlying Commission policies.

Corning charges that Staff's suggested methods for further austerity adjustments lack any record basis. Corning urges the Commission not to make any such adjustments because they would be antithetical to the Commission's ratemaking process.[5] This would be illegal, Corning also argues, because they are unsupported by any clearly established nexus between the customer impacts of the COVID-19 pandemic and the issues raised in this rate case.[6]

We discuss these austerity adjustments in greater detail below.

1) Amortization of Regulatory Assets and Liabilities

As of the end of the Historic Test Year, Corning is expected to have $2.864 million of regulatory assets, i.e., moneys owed to the Company, and $0.916 million of regulatory

[5] Company Reply Brief at 2.

[6] Company Reply Brief at 4 and note 13.

liabilities, i.e., moneys owed to ratepayers.[7] To further mitigate the revenue requirement increase, Staff notes that the Commission could accelerate the return of regulatory liabilities to customers and/or defer the Company's collection through rates of regulatory assets. In choosing an approach, Staff recommends weighing the benefits of mitigating the increase in revenue requirement against the costs, to customers, of delaying the Company's collection of regulatory assets.[8] Staff notes that amortizing all new deferrals over ten years would reduce the revenue requirement by approximately $269,972.[9] Alternatively, Staff notes, the Commission could choose to not amortize any regulatory assets in the Rate Year but pass regulatory liabilities back to customers over five or three years. These two options would reduce revenue requirement by approximately $631,884 or $728,348, respectively.

2) Removing the Allowance for Management Wage Increases in the Rate Year

In testimony and its initial brief, Staff recommended allowing union and management wage increases at the general rate

---

[7] Staff Initial Brief at 6. For each new deferred asset or liability, including deferred Pension and OPEB costs, the Company proposes to amortize the forecast balances as of January 31, 2021 over a three-year period. Tr. 86, Ln. 1-2, Tr. 87, Ln. 5-6; Staff Initial Brief at 22. Staff disagrees and recommends that, for all new deferrals, except rate case expenses, the actual deferral balances as of the end of the Historic Test Year be amortized over five years, to mitigate the potential rate increase. Tr. 766, Ln. 10-13. For rate case expense, Staff argues a three-year amortization period is appropriate because the Company has historically entered into three-year rate plan agreements. Staff Initial Brief at 22-23. Staff's initial brief incorrectly stated that these balances were as of the beginning of the Rate Year, however we have been advised that the correct time period of these amounts is as of the end of the Historic Test Period.

[8] Staff Initial Brief at 7.

[9] Staff Initial Brief at 7.

of inflation, or 1.34%.[10] However, based on current economic conditions due to COVID-19, Staff suggested that the Commission could consider reducing management wage increases to 0% in the Rate Year and thereby reduce the revenue requirement by $5,139.

Corning contests Staff's proposed 1.34% limit on wage increases based on the general rate of inflation. Corning argues that a 3% increase in wages is necessary to retain its employees. Corning also challenges Staff's assertion that the Commission is authorized to freeze management wage increases based on general concerns about the adverse economic impacts of the COVID-19 pandemic.

3) Removing the Allowance for Certain Proposed New Employees

Staff suggests the Commission could deny cost recovery for four new employees and a contractor that Corning has proposed.[11] This approach, Staff argues, would reflect the fact that many businesses have imposed hiring freezes, and/or terminated or furloughed employees due to financial constraints associated with the COVID-19 pandemic. Imposing temporary limits on Corning's ability to hire new staff, Staff reasons, may be appropriate given these circumstances. Disallowing all four employees and the contractor would reduce the revenue requirement by approximately $344,513. Alternatively, Staff suggests, the Commission could limit the adjustment to only reflect new employees not yet hired by Corning.

Corning opposes this adjustment, arguing that its testimony demonstrates that these new employees will pursue significant tax and operating cost savings that are expected to

[10] Tr. 689, Ln. 3-9; Staff Initial Brief at 17-18.

[11] The Company has asked for cost recovery relating to retaining an information technology (IT) contractor or hiring four new employees: one IT employee, two gas specialists and one laborer. Staff Initial Brief at 8.

offset their salaries and the Company is prepared to reduce future rates to reflect savings that might be achieved.[12]

4) Removing the Accelerated Amortization of Leak-Prone Pipe

Corning's proposed depreciation expense included the amortization of the remaining plant balance associated with LPP over a seven-year period. In testimony, Staff agreed with amortizing the remaining LPP plant balance over the time period of expected removal, to limit intergenerational inequity and reduce rate base for assets no longer used and useful. However, Staff suggests that, to reduce rate impacts on customers, amortization of the remaining LPP plant balance could be pushed outside of the Rate Year and addressed in a future rate proceeding. This would decrease revenue requirement by approximately $439,206.

Corning argues this proposed adjustment has no record basis and, if adopted, will cause intergenerational inequity and lead to significantly increased rates in the future. Corning asserts that, for these reasons, this proposed adjustment must be rejected by the Commission.[13]

DISCUSSION

Over the past fifteen months, because of the COVID-19 pandemic, all State residents have been forced to make hard sacrifices and to bear up under extraordinary and unforeseen circumstances. The Commission cannot ignore the pandemic-related economic hardships caused by the COVID-19 pandemic. When setting rates, we must make adjustments that account, in some degree, for the economic fallout from the pandemic. Failing to do so would, in effect, impose additional hardships

[12] Company Reply Brief at 10-11.

[13] Company Reply Brief at 11.

on ratepayers at a time of unusual and unexpected need. The austerity adjustments offered by Staff are warranted due to the current extraordinary circumstances. While Corning argues recent events have suggested that things are getting better, that is not a rational basis for ignoring what actually happened in the recent past. On the other hand, it is reasonable to require the Company to bear part of the economic burden of recent events.

Accordingly, we adopt Staff's suggested austerity adjustments relating to removing the allowance for management wage increases in the Rate Year; removing the allowance for certain proposed new employees; and, removing the accelerated amortization of LPP. To further mitigate the revenue requirement increase, we will also accelerate the return of regulatory liabilities to customers and/or defer the Company's collection through rates of regulatory assets. In deciding which approach to take, we have weighed the benefits of mitigating the revenue requirement increase against the costs, to customers, of delaying the Company's collection of regulatory assets. We find that an appropriate balance between these competing concerns can be struck by amortizing all deferred regulatory assets, including both pension and Other Post-Employment Benefits ("OPEB") amounts, over a ten year period, and amortizing all deferred regulatory liabilities, other than the OPEB deferral, over a three year period.[14] This will reduce the increase in the Company's revenue requirement by approximately $466,905. These measures, along with the other austerity measures described above, will mitigate the increase in the Company's revenue requirement, and thereby protect the

[14] See Appendix X for a full list of regulatory deferrals and amortization periods.

interests of ratepayers in the context of the still-ongoing COVID-19 pandemic.

Most of the adjustments identified in the prior paragraph fall squarely within the discretion of the Commission in that they are based on underlying Commission policies and thus need not be grounded in any evidentiary record colloquy. It is sufficient that these matters have been raised and countered in the overall case record in the parties' briefs. Although Corning's request for management wage increases and to hire employees for newly created positions are not associated with any underlying Commission policies, we find that Corning has not met its burden with respect to these matters. Specifically, we find that the need to employ austerity measures far outweighs the Company's need to increase management salaries and add these new positions. We also note that the rates at issue in this case will have a one-year duration and, should the economy recover in the interim, such austerity measures would likely not need to be employed in future rate cases.

B. Estimated Sales and Revenues

1. Sales Forecast

Staff made a number of adjustments to the Company's sales forecasts. The Company accepted all of Staff's adjustments and there are no remaining areas of disagreement on this topic.[15] The calculations in Appendix 2 reflect these agreements.

2. Local Production Revenues

The Company accepts Staff's adjustments to delivery revenues, local production revenues, and other transportation

[15] Staff Initial Brief at 10; Company Initial Brief at 10; Company Reply Brief at 15.

revenues.[16] The calculations in Appendix 2 reflect this agreement.

3. Other Revenue Issues

Staff and the Company also agree to continue the mechanism established in the 2017 Rate Order in Case 16-G-0369[17] estabishing annual revenue targets and sharing the difference between the actuals and the targets between customers (85%) and shareholders (15%). Staff and the Company agreed to revenue imputation targets of $1,650,029 for contract revenues and $263,201 for local production revenues, with no changes to the sharing mechanism.[18] While we accept this agreed-upon mechanism, certain contract revenues are dependant on firm delivery rates, and therefore, the contract revenue imputation target needs to be updated to reflect the base delivery rates adopted in this Order. As such, the imputed contract revenue target is set at $1,472,455.

Staff and the Company also agree to Staff's adjustments to the Revenue Decoupling Mechanism ("RDM") to use a revenue per class RDM target rather than a revenue per customer RDM target,[19] Merchant Function Charge target revenue of $40,813 for credit and collections and $82,884 for gas supply

19 Staff Initial Brief at 14; Company Reply Brief at 14.

procurements[20], and an uncollectible rate of 0.464% rather than 0.565%.[21] We accept these agreements.

C. Operation and Maintenance Expenses

1. Direct Labor

Staff and the Company agree on Staff's adjustments to set overtime expenses at a three-year average and to correct the vacation accrual.[22] Three of Staff's other direct labor adjustments are disputed: (1) disllowance of the costs of one proposed new IT employee; (2) disallowance of the costs of the Company's incentive compensation plan; and (3) a wage increase of 1.34% based on the general inflation rate rather than the Company's proposed 3% increase. As discussed below, we agree with the first two of Staff's adjustments. In addition, as discussed above in the section on Austerity Adjustments, we are making additional adjustments regarding new employees and management wage and salary increases. The discussion immediately below relates to the specific adjustments proposed in Staff's testimony.

a. Additional IT Employee.

Staff proposed to disallow the costs of two proposed new IT employees. The Company agreed to the removal of the costs of one of the two.[23] Staff argued that the Company's justification was inadequate because the work of the disputed employee is already being handled by other Company employees, and because the tax savings alleged by the Company to be provided by the work of the new employees were not reflected in

[20] Staff Initial Brief at 14; Company Reply Brief at 16-17.

[21] Id.

[22] Staff Initial Brief at 16; Company Initial Brief at 13; Company Reply Brief at 17.

[23] Staff Initial Brief at 18-19; Company Initial Brief at 13; Company Reply Brief at 17-19.

the Company's case. The Company argues that the tax savings will primarily be reflected in future years (and therefore future rate cases), but agrees to notify the Commission of any savings achieved during the Rate Year. We agree with Staff's adjustment. Given the Company's claim that the savings achieved by the employee will more than cover the salary costs[24] and the Company's failure to offset any of the salary costs by expected savings in its case, we disallow the costs of the disputed employee position.

b. Incentive Compensation Plan

Staff proposed to disallow recovery of the costs of the Company's management incentive compensation plan. As Staff testified, the Commission requires a company to make one of two showings for the costs of such a plan to be allowed: (1) that the Company's total level of employee compensation inclusive of incentive pay is reasonable relative to peer companies and that the incentive pay does not contain performance targets that adversely affect customer interests or are inconsistent with Commission policies; or (2) that the incentive pay plan provides quantifiable or demonstrable benefits to customers, in a financial sense, or in terms of reliability, environmental impact or customer service.[25] Staff argues that the Company failed to make either of these showings with respect to its incentive compensation plan. Staff notes that the Company did not provide a compensation study, and that the majority of incentives focus on goals that benefit shareholders, especially in light of the provision of the plan that no incentive is paid if the earnings target is not achieved.[26] The Company argues

[24] Company Reply Brief at 17.

[25] Tr. 923-926.

[26] Hearing Exh. 36 (DSG-1, p. 1); Tr. 927-928.

that all of its business and the work of all of its employees are dedicated to achieving safety, reliability and customer service and that disallowing the costs of the incentive program would send the wrong signal to the Company's employees.[27] The Company also argues that the plan's financial performance goals benefit customers by maintaining the financial strength and solvency of the Company.[28]

We are not persuaded by the Company's arguments. They are broad, general and would justify virtually any incentive compensation plan. We find that the Company has not made the specific showings required by Commission policy, and we adopt Staff's adjustment.

c. Wage Increase.

Staff proposed in testimony to limit the allowed wage increases in the Rate Year to the general inflation rate. The Company proposes a 3% increase. The Company's union contract expired on April 5, 2021,[29] thus requiring a forecasted amount for the Rate Year. Staff's position was that the Company's forecast of 3% was not appropriate in light of the uncertainties of the COVID pandemic, and that the inflation rate should be used to forecast Rate Year wage increases.[30] Staff agreed that the Company could update the record during the course of this proceeding in the event of material changes in union negotiations,[31] but there were no such updates as of the date briefs were due.[32] The Company in its Initial Brief reported a tentative agreement with the union "consistent with the level

---

27 Company Reply Brief at 19.

28 Company Initial Brief at 13-14.

29 Tr. 83.

30 Tr. 687-688.

31 Tr. 688.

32 Staff Initial Brief at 17.

projected by the Company for the rate year".[33] In its Reply Brief the Company stated that it expected a contract to be finalized "within a few days."[34] In its May 5 and May 6, 2021 letters the Company informed the Commission that a collective bargaining agreement has been reached and ratified by union membership vote. In the May 5 letter, the Company stated that, although the agreement provides for wage increases of 3.5%, 3.5% and 3.0% for years 1-3 of the agreement, the Company would adhere to its 3.0% Rate Year request in this case. The Company also argues that its forecast is reasonable and consistent with past history and that it may lose employees if its wages are non-competitive.[35]

We will allow a 3% wage increase applicable to the Rate Year as requested by the Company. It is standard Commission practice to recognize completed collective bargaining agreements during the pendency of the case and, as noted above, Staff agreed that the Company could update the record during the course of the proceeding.[36]

2. Insurance

Staff and the Company agree on the use of the latest-known Gross Domestic Product ("GDP") Deflator as the general inflation rate applied to property insurance, injury and damages, other insurance, life insurance and plan administrative costs.[37] The parties disagree on the Rate Year forecast of health care costs. The Company proposes a 10% increase, and Staff applies the general inflation rate. The Company testified

---

33 Company Initial Brief at 16.

34 Company Reply Brief at 19.

35 Tr. 83, 114-115; Company Initial Brief at 15-16.

36 However, we make an additional adjustment to management wages and salaries in the section above on Austerity Adjustments.

37 Tr. 700, 724-725; Company Reply Brief at 21.

that health care costs increase at a higher rate than average cost increases.[38] Staff testified that the general pool of costs subject to the general inflation rate includes some costs that are higher and some costs that are lower than the the general inflation rate, and that the inclusion of health care cots in the general pool of costs is consistent with long-standing Commission practice.[39] Staff cites the June 26, 2014 Order Establishing Rates in Case 13-W-0235[40] as the most recent statement by the Commission of its policy, followed since 1986, that:

> ". . . in the generic inflation pool, by its nature, some costs are fully expected to increase faster than general inflation rates while others are not. If medical expense falls into the former category … that does not alter the fact that the generic inflation rate is an average of inflationary and deflationary changes in the prices of all the various goods and services in the pool. Thus, a deviation between the increase in a single pooled cost item such as medical expense, relative to the average increase, does not justify removing that item from the pool in an attempt to predict it separately."

The Company has not convinced us that we should change this policy, and we adopt Staff's adjustment.

3. Regulatory Expenses and Amortizations

Staff and the Company agree on the amounts of regulatory and rate case expenses, on the assumption that the rate case expense amount will be amortized over three years based on the actual amount as of the time of the Commission decision.[41] However, as previously discussed, we are delaying

---

38 Tr. 65-67; Company Initial Brief at 18-19.

39 Tr. 803, 931-933; Staff Initial Brief at 15-16.

40 Case 13-W-0235, United Water New York Inc. – Rates, Order Establishing Rates (issued June 26, 2014).

41 Staff Initial Brief at 21-22; Company Initial Brief at 20-22; Company Reply Brief at 23-24.

the Company's collection of its regulatory assets as a means of mitigating the revenue requirement increase. Accordingly, rate case expenses will be amortized over ten years, consistent with other deferrals assets.[42]

Regarding regulatory expense deferrals, the Company objects to Staff's calculation of the balances as of the end of the Historic Test Year as opposed to forecasting them for the Rate Year. The Company argues that forecasting is "normal Commission practice"[43] but fails to cite any Commission precedent. Staff's position is that the Historic Test Year balances have been audited but that forecasted balances cannot be audited.[44] We accept Staff's position for the reason stated by Staff.

Staff and the Company also disagree on the time period for amortization of deferrals other than rate case expenses. The Company's position is that a period longer than three years risks overlapping with the next rate plan, that prior rate plans have used a three-year period and that the period should be consistent with the period of amortization of rate case expenses.[45] Staff proposes a five-year period given the potential for large rate increases in this case and the uncertainties facing ratepayers during the COVID epidemic.[46] We reject both the Company's and Staff's amortization periods. As discussed, we are modifying the Company's amortization of its regulatory assets and liabilities as a means of mitigating the

---

42 A listing of Corning's deferred debits and credits for the rate year ending January 31, 2022 is contained in Appendix 3.

43 Company Reply Brief at 24.

44 Tr. 765-766; Staff Initial Brief at 22.

45 Tr. 117-118; Company Initial Brief at 22; Company Reply Brief at 24.

46 Staff Initial Brief at 23.

revenue requirement increase. Accordingly, all regulatory assets will be collected from customers over ten years and all regulatory liabilities, with the exception of the OPEB deferral, will be passed back to customers over three years.

Staff and the Company also disagree on recovery of $349,547 of survey and repair costs related to cold weather that were incurred in 2015. This issue was first raised in a deferral petition that the Company filed on April 13, 2016[47] and remains pending. The Company proposes a three-year amortization of the amount in question. Staff's position is that the Company's request fails to meet the second prong of the Commission's three-prong test for eligibility for deferral treatment and that the Company's deferral petition should be rejected. The parties agree that the request meets the first prong (the expenses are incremental to the amount allowed in rates) and third prong (the Company cannot earn above its authorized rate of return). The dispute is over the second prong: that the incremental amount must be material and extraordinary in nature. The parties agree that the amount is material, and the dispute is therefore over whether the expenses were extraordinary.

The Staff Accounting Panel testified that the expenses were not extraordinary in nature. Staff's analysis is based on the overall heating degree days during the winter of 2015, noting that the winter was only 1.7% colder than the previous winter.[48] Staff also noted that no other gas utility undertook a similar survey of its entire system in 2015.[49] The Company's

47 Case 16-G-0204, Corning – Petition to Defer Leak Survey and Repair Costs Over and Above the Level Established in Rates.

48 Tr. 752; Hearing Exh. 37 (SAP-2); Staff Initial Brief at 25-27.

49 Tr. 752-753.

position is that the January to February period of that winter was extremely harsh and that frost was deeper than had been experienced in a long time.[50]

We accept Staff's position and deny the Company's deferral petition. Every winter has periods of time that are significantly colder than average. The appropriate period of time for determining whether cold weather is extraordinary is the entire winter, not the period of a particular cold temperature event. As a whole, the winter of 2015 was not materially colder than the previous winter, and it is a common occurrence for heating degree days in January and February to be significantly colder than average in any winter.[51] We also find it noteworthy that other gas utilities did not undertake a similar systemwide survey and repair program during the winter in question.

4. Pensions and Other Post-Employment Benefits

The Company agreed to Staff's adjustments to pensions and OPEBs except for the appropriate period of amortization of new deferrals. As with regulatory expenses, Staff proposes a five-year period and the Company proposes a three-year period. For the reasons discussed above for regulatory expenses,[52] we reject both the Company's and Staff's recommended amortization periods. The pension and OPEB deferrals will be amortized over ten years.

5. Other Expense Items

Staff and the Company agree on many of the remaining expense items, including the costs of pension and OPEB

---

50 Tr. 118-119; Company Initial Brief at 23-24.

51 See data for 2013, 2014 and 2015 in Hearing Exh. 37 (SAP-2, page 321).

52 Staff Initial Brief at 22-23; Company Initial Brief at 25; Company Reply Brief at 27.

management, uncollectibles,[53] the low income program, building services, transportation, outside services, inventory and Other O&M.[54] We accept these agreements.

We also note the parties' agreement to eliminate credit and debit card payment fees charged to customers, with an allowance in rates for the relevant costs. The Commission welcomes this agreement and notes that it will save customers approximately $8,000 per year.[55]

6. Productivity

Staff proposes a 1% productivity improvement imputation in the Rate Year forecast of direct labor expense, employee fringe benefits expense and payroll taxes, asserting that this adjustment reflects a long-standing Commission policy to capture unidentified and/or unquantifiable productivity gains, efficiencies and cost savings that could be realized in a Rate Year.[56] The Company opposes such an adjustment, stating that it has already increased productivity by reducing costs, and that the application of the general inflation rate to health care expenses is effectively a productivity adjustment.[57]

We have explained above why the use of the general inflation rate is appropriate for health care expenses as part of a large pool of expenses that are subject to cost increases.

---

53 Staff and the Company agree that the Company may file a petition to defer the difference between actual and rate year forecast uncollectibles. Company Initial Brief at 27. Staff clarifies that such a petition must meet the Commission's standard three-prong test for eligibility. Staff Reply Brief at 7. We concur with Staff's clarification.

54 Company Reply Brief at 28-33 reflects these agreements.

55 Company Initial Brief at 29-30; Staff Initial Brief at 103-104; Company Reply Brief at 29.

56 Tr. 824, 827-828; Staff Initial Brief at 21-22.

57 Tr. 63-67; Company Initial Brief at 35-37.

We are not persuaded that the Company's forecasted Rate Year savings capture the level of productivity improvements that the Company can and should achieve. We are also not persuaded that we should abandon our normal practice of imputing a productivity adjustment, and we therefore adopt Staff's proposed productivity adjustment.

7. Taxes

For the most part, the parties are in agreement on tax issues, including property taxes, payroll taxes, revenue taxes, and state and federal income taxes.[58] Staff and the Company also agree to remove from this case and to address in a future rate case the appropriate deferred federal income tax refund balance associated with the federal income tax savings due to customers for the Tax Cuts and Jobs Act of 2017 corporate federal income tax rate reduction.[59] We accept these agreements. An in depth analysis is required to reconcile and determine the tax savings amount that should have accrued to customers as compared to the amount that has been provided to customers by the tax savings sur-credit implemented October 1, 2018. The amount that is determined to be an over or under passback of savings, will be accounted for in the deferred federal income tax refund account. The only area of disagreement related to taxes is Staff's proposed amortizaton of accumulated deferred income taxes over an average depreciable life of 42 years for long-lived assets as opposed to the Company's proposed 30-year amortization for such assets in accordance with its proposal to depreciate all long-lived assets over a 30 year period.[60] Because we are rejecting the Company's 30-year depreciation proposal, we accept Staff's

[58] Company Reply Brief at 42-47; Tr. 123-124.

[59] Staff Initial Brief at 33; Company Reply Brief at 43.

[60] Company Reply Brief at 46-47.

proposal for amortization of accumulated deferred income taxes.

8. Depreciation Expense

By far the largest issue in this case, amounting to nearly half of the requested rate increase,[61] is the Company's proposal to depreciate its long-lived assets by 2050, a 30-year period, as opposed to the depreciation lives that would result from the Company's depreciation study. The Company argues that, because the CLCPA mandates the reduction of statewide greenhouse gas emissions by 85% of 1990 levels by 2050, the statute "effectively shortens the effective life of the Company's existing and future investments in infrastructure."[62] The Company further argues that the CLCPA will reduce customer demand and increase the cost of capital. The Company asserts that the proposed shortened lives "will allow the Company to continue its systematic replacement program with more internally generated funds."[63] The Company also asserts that delay in adjusting its depreciation rates in this case "effectively kicks the can down the road" and would only lead to higher rates in the future.[64]

Intervenor Bob Wyman supports the Company's proposed useful lives for the same reasons stated by the Company.[65] Mr. Wyman agrees that the Company's proposal involves some degree of speculation, but argues that all ratemaking necessarily involes forecasting and some degree of speculation. In this case, Wyman argues, the Company's proposal is reasonable and well-grounded.[66]

62 Tr. 52-53.

63 Id; Company Initial Brief at 38-39,

64 Tr. 123.

65 Bob Wyman Initial Brief at 3-6.

66 Bob Wyman Reply Brief at 5-11.

Staff responds that any change in depreciable lives at this time is premature, because it is unknown how the CLCPA will be implemented.[67] Staff also raises concerns about the bill impact of the change, particularly in light of the COVID epidemic.[68] UIU also opposes the shortening of useful lives proposed by the Company. UIU argues that the CLCPA does not explicity state that all gas assets will be retired by 2050, nor has it been determined what role, if any, pipeline infrastructure will play in reaching the CLCPA's goals.[69] UIU also notes that when the Rochester Gas & Electric ("RG&E") steam system in Rochester was retired as no longer profitable, shareholders took on a significant portion of the costs of retirement and assets were transferred to a newly-formed municipal corporation to create a district loop.[70]

We reject the Company's proposal for shortened asset lives and adopt Staff's adjustment.[71] Logically, the shortening of depreciable lives to a 2050 end-point amounts to a forecast that the Company will cease utility operations by 2050 and that none of its assets at that time will have any value. Because the Company has not met its burden of proof that such a result is probable, we find the Company's position to be speculative. It simply does not follow that a target of 85% statewide greenhouse gas reductions by 2050 means that the Company will close up shop by 2050 and that none of its assets will remain in

---

67 Tr. 419-420; Staff Initial Brief at 27-29.

71 A schedule showing the Rate Year Depreciation Expense is attached as Appendix 4.

service. It is impossible to make a precise forecast at this time of what the Company's business will look like in 2050, but it is clear that the assumption that the Company will be out of business at that time is at the extreme end of many possibilities. These possibilities include business as usual if the State's climate goals can be met through other means, the total or partial use by the Company of renewable natural gas supplies, and the total or partial conversion of the Company's system to renewable hydrogen gas. All of these alternatives are consistent with a financially healthy gas utility using its existing assets long after 2050. UIU is also correct that in an arguably similar situation when RG&E retired its steam system in Rochester, some of the utility assets still had a useful function, and RG&E's shareholders bore much of the cost of early retirement.

Further, several of the Company's rationales – that the CLCPA will lead in the future to lower revenues and a higher cost of capital and that the adjustment will provide more internally generated funds for the Company's capital program – have little to do with the depreciation expense allowance in this case. If revenues decline and the cost of capital increases in the future, those matters will no doubt be raised by the Company in future rate cases, and the Commission will address them at that time. The fact that the shortened lives would give the Company more internally generated funds for its line repleacement program is not a justification for the depreciation proposal. Such an argument could be made for any ratemaking adjustment that gives the Company more cash at the expense of its customers. The argument does not establish that the proposal is appropriate.

It also appears that the Company itself may not believe in its forecast. If the Company truly believes that its

assets will be valueless in 2050, the financial statements that the Company's parent holding company provides on a quarterly and annual basis to the investment community and to the Securities and Exchange Commission should fully reflect these dire circumstances. However, as admitted by the Company's Chief Financial Officer, although the Company's operations are fully reflected in the parent company's financials, the shortened depreciable lives proposed in this case are not reflected in its recent SEC 10-Q and 10-K financial statement filings.[72] It appears to the Commission that the Company is claiming materially worsened financial circumstances to justify a large rate increase, while at the same time it presents financial statements to the investment community on a business-as-usual basis that is at odds with the greatly reduced asset lives claimed in this case.[73]

For these reasons we reject the Company's proposal to depreciate all of its assets by 2050. We are not just "kicking the can down the road." We find that the Company has not demonstrated that its proposed useful lives are anything more than speculation. The dire circumstances raised by the Company are far from the only potential outcomes from the CLCPA. If in the future we were to take the drastic step of directing a regulated gas utility to cease operations, the mechanism to do so would not be what the Company proposes in this case – a large transfer of cash from ratepayers to shareholders. We note also that the Company proposes no plan for its customers to transition away from gas by 2050 and proposes no limitations on

[72] Tr. 166-167.

[73] We note that shortening the asset lives and increasing depreciation expense in the relevant 10-K and 10-Q financial statements would have negatively impacted the reported net income of the Company's parent.

its use of the proposed incremental ratepayer funding. The implementation of the CLCPA by the Commission will be difficult, complicated and potentially expensive, but however it is implemented the plan will not look like what the Company has proposed here.

9. Inflation

The parties agree on the use of the GDP deflator at the time of the Commission decision as the general inflation rate.[74] We accept this agreement.

D. Rate Base

1. Plant in Service and Capital Spending

Staff and the Company disagree on three plant in service and capital spending issues: (1) an increase by Staff in the capital budget to maintain the replacement of bare steel mains at 10 miles per year, rather than the 8.6 mile figure proposed by the Company; (2) Staff's deletion of two projects that were funded in the Company's preceding rate case but not accomplished; and (3) Staff's proposal to continue the downward-only reconciliation mechanism for net plant investment targets in the Rate Year.

We accept Staff's adjustment to the bare steel main replacement program. The Company proposes to decrease the replacement program from 10 miles to 8.6 miles per year "as a COVID mitigation measure."[75] While we appreciate the concern of the Company in this respect, the public safety concerns related to bare steel pipe outweigh the relatively minor decrease in

[74] Company Initial Brief at 17; Staff Initial Brief at 21; Company Reply Brief at 21, 31.

[75] Company Reply Brief at 39.

capital spending that the Company proposes.[76] We therefore direct the Company to maintain its current program of 10 years of pipe replacement per year, and we make allowance for that capital spending in the revenue requirement calculation in this case.

We also accept Staff's proposed disallowance of capital spending for two projects, totalling $230,000, because the Company's last rate case already included funding for these projects.[77] The Company responds that although it did not perform these projects, it expended the allowed capital budget funds on other projects, and that the Commission's capital budget allowance allows for flexible allocations of funding among projects as long as the total allowed budget is spent.[78] Although we agree with the Company that funding these projects a second time would not amount to double recovery of the allowed capital spending in the last rate case, the Company clearly has placed low priority on these projects. We are not convinced that the Company would complete them if we included their costs a second time in this rate case. In other words, the Company has not met its burden to establish that it would actually complete these projects if given a second bite at the apple, and we are concerned that the Company would again use the allowed funds for other projects of its choosing that it did not reflect in this case. A schedule listing our allowances for Corning's Capital Expense Budget is contained in Appendix 5.

We also accept Staff's proposed continuance from the Company's last rate case of the downward-only reconciliation

---

[76] The parties agree on the size of the Company's replacement program for unprotected service lines. Staff Brief at 34.

[77] Tr. 411-414; Staff Initial Brief at 35-36.

[78] Company Reply Brief at 40.

mechanism of net plant targets for the Rate Year.[79] This mechanism protects ratepayers against paying for capital expenditures in an amount greater than the Company incurs. The Company argues that although this mechanism has been used in the Company's last three rate cases, it is unnecessary in a single-year rate case because ratepayers are fully protected by the penalties applicable if the Company misses its leak-prone pipe replacement targets.[80] We agree with Staff and will continue the downward-only reconciliation mechanism. The pipe replacement program penalties cover only a portion of the Company's net plant investments, and we see no reason to remove the protection that the ratepayers have had for the last three rate cases against underspending by the Company. Appendix 6 shows the net plant true-up targets, as well as an example for how the true-up calculation is performed.

2. Reporting Requirements

Staff recommends that the Commission require capital expense and variance reporting. These reports should include: (1) a final variance summary of capital expenditures for all capital projects and programs including all on-going and active construction projects and programs; (2) a narrative explaining any cost or timeline differences from estimated costs in the project's white paper; (3) a narrative on project design, permitting and/or construction status, including a detailed construction schedule for each project, for any ongoing projects; and (4) a description of any new projects or programs with, at minimum, information that is provided in a white paper.[81] Staff asserts that it is important for Staff and the

[79] Tr. 422-423; Staff Initial Brief at 37.

[80] Company Reply Brief at 41.

[81] Tr. 423-424; Staff Initial Brief at 38.

Commission to monitor the Company's capital work, and that the reports should be filed with the Commission Secretary within 45 days after the end of each calendar year.[82]

The Company objects to the proposed reporting on the ground that no allowance is made for the costs of staff to prepare the reports. The Company also objects to a filing date 45 days after each calendar year because the applicable data will not be available until approximately 30 days after the end of the year, leaving only 15 days to compile and file the reports. The Company suggests a minimum of 90 days to file the reports.[83]

We adopt Staff's position on the need for the reports. We are not convinced that the additional reporting costs would be so material that they require an adjustment to the revenue requirement in this case. However, the Company makes a reasonable argument about the due date of the reports. To minimize the incremental costs and difficulty of reporting we accept the Company's proposal that the reports shall be due 90 days after the end of the calendar year.

E. Cost of Money

1. Capital Structure

Staff and the Company dispute certain elements that make up the Company's overall after-tax rate of return. After accounting for these differences, Staff recommends that the Commission provide Corning with a return of 6.07% compared to Corning's request of 7.28%. The difference is attributed to disputes over the cost of equity, the common equity ratio, and the cost of long-term debt. In summary, Staff urges the

---

82 Id.

83 Company Reply Brief at 44-45.

Commission to reduce Corning's requested cost of equity from 10.20% to 8.45%, common equity ratio from 50.77% to 48.00%, and cost of long-term debt from 4.45% to 3.91%.[84]

Underlying the dispute are the parties' positions on whether using a stand-alone capital structure is appropriate in this matter. Corning proposes the use of such a structure for setting its rates, while Staff, despite providing an analysis of and corrections to the Company's stand-alone capital structure, proposes the use of a hypothetical capital structure to set rates. Staff's recommendation is based on the assertion that it is not clear if the Company and its parent are employing rational financing policies because of the use of preferred equity in the parent company's capital structure. In this respect, Staff notes that it is difficult to determine the extent to which the parent company is effectively leveraged relative to Corning. Staff posits that it would not be appropriate to authorize rates predicated on either Corning's stand-alone capital structure or the consolidated capital structure of the parent because of this difficulty.[85]

Corning counters that a stand-alone structure is appropriate because the Commission has already determined that its ring-fencing measures are appropriate in its 2013 order approving of a Joint Proposal that established the use of a

[84] Staff Initial Brief 39-40. Staff notes that in terms of revenue requirement, a 1% change in the common equity ratio is worth approximately $51,693 and a 10 basis-points change in return on equity (ROE) is worth approximately $44,612.

[85] Staff Initial Brief 41-43.

holding company between Corning and its parent.[86] Corning also notes that Staff's approach ignores the fact that Corning's relatively small size negatively impacts its ability to access capital markets on reasonable terms.

Staff counters that, although the Commission has sometimes allowed the use of a stand-alone capital structure in setting rates where sufficient ring-fencing exists, Corning's Affiliate Standards do not rise to that level. Staff notes that, while Corning's measures were determined to be adequate for establishing the Holding Company, the Commission has not determined that they are sufficient for rate-setting and observes that there are deficiencies from what Staff determined would be suitable in its testimony in Case 16-G-0257.[87] By way of example, Staff observes that Corning has neither implemented a "golden share" provision to prevent the bankruptcy of the parent company or affiliates from affecting the Company, nor issued a non-consolidation letter to demonstrate the implementation of ring-fencing and the creation of the separate legal and credit entity for the utility subsidiary. Staff states that, in the absence of sufficiently strong ring-fencing provisions, the Commission typically compares the stand-alone capital structure of the utility to the consolidated capital structure of the utility's parent in order to ascertain whether they reflect rational financing policies. Staff concludes that because of its concern the Commission should instead use its

---

86 Corning Reply Brief 57-58 (citing Case 12-G-0141, Petition of Corning Natural Gas Corporation for Authority to Form a Holding Company and for Approval of Certain Related Transactions, Order Adopting Terms of a Joint Proposal and Approving Formation of a Holding Company, with Modifications and Conditions (issued May 17, 2013)).

87 Staff Initial Brief 44. Case 16-G-0257, National Fuel Gas – Rates.

proposed hypothetical capital structure.[88]

We agree with Staff. In particular, Corning's reliance on recent Commission-authorized weighted equity cost rates in New York is misplaced. Those rates were set in the context of multi-year plans. Given that Corning is making no commitment to delay any new rate filing, there is no additional risk to its investors. As for the other issues raised by Corning to support its request that we set rates using the Company's proposed equity ratio of 50.77%, we have reviewed the record and do not find it convincing. In particular, the Company's concerns about its cash flow do not convince this Commission that adjustments in favor of higher utility rates are warranted, particularly where the higher equity ratio would be borne by the utility's customer base through higher rates. While the record is devoid of evidence that Corning's requested 50.77% equity ratio is actually achievable, we also do not see it as a viable figure on which to set the Company's rates. As Staff notes, at best, Corning could be expected to maintain a stand-alone equity ratio of only 48.05% during the Rate Year.[89] To set rates based on an equity ratio higher than the actual rate borne by the Company would unreasonably shift additional costs on customers. Thus, we find that it is appropriate in this instance to employ a hypothetical capital structure and set the Company's rates using a common equity ratio of 48.00% as recommended by Staff.

2. Cost Rates

As for cost rates, Staff and the Company agree on the rates we should use for customer deposits and short-term debt.[90]

---

88 Staff Initial Brief 44-45.

89 Staff Initial Brief 47.

90 Corning Initial Brief 68.

The Commission annually sets the customer deposits rate which is currently at 0.05% and is appropriate here. For the cost of short-term debt, Corning forecast a rate of 3.78% and it was not disputed by Staff. We adopt this rate.

3. Long-Term Debt

Corning's requested long-term debt cost of 4.45% is based on the actual or estimated cost of each debt issuance reflecting the effective interest to Corning.[91] There is no real dispute as to the embedded costs used to calculate the Company's long-term debt cost. Instead, Staff takes issue with Corning's projections regarding anticipated new debt issuances that Staff disputes and makes an ultimate recommendation for the Commission to employ a long-term debt cost of 3.91%. Staff attributes the difference to a largely resolved correction related to three outstanding loans, as well as to disputes regarding the amounts and timing of the Company's future borrowing and the cost rate estimates for those anticipated new issuances.[92]

The two parties contest the significance of representations from an M&T Bank communication to Corning indicating that the applicable interest rate for new debt securities would be fixed at 4.75%. The Company claims that this figure is reliable and offers in brief another letter from M&T Bank received post-hearing that ostensibly indicates that, at present, Corning would be charged a rate of 4.57%, which the Company says favorably compares to its requested 4.45%.[93] Staff observes that the M&T Bank letter related to the 4.75% interest rate does not communicate any reliable estimate of the interest rate the bank would require on a loan to Corning during the Rate

91 Corning Initial Brief 68.

92 Staff Initial Brief 48.

93 Corning Initial Brief 68.

Year.[94]

Staff proposes that the Commission look instead to other evidence in the case that demonstrates how M&T Bank determines interest rates when it lends to Corning and apply that formula. Staff notes that M&T Bank calculates the interest rate of 10-year loans at 1.80 percentage points above the yield on the 10-year Treasury and it fixes the interest rate on three-year debt at 3.00 percentage points above the three-year Treasury plus the ask side of the three-year London Interbank Offered Rate ("LIBOR") swap spread. At the time of Staff's testimony, the 10-year Treasury was trading at 0.66% and there was no change forecasted, indicating that Corning's 10-year debt issuances during the Rate Year would be issued at a cost of 2.46%. Also, the three-year Treasury was trading at 0.20% with the three-year LIBOR swap spread equal to 0.06%. With the addition of a spread of 3.00%, the resulting estimate for a cost of 3.26% for Corning's three-year debt issuances during the Rate Year.[95]

We agree with Staff that its formula serves as a reasonable proxy for a litigated result. We adopt that approach noting that we are updating the forecasts for the formula's components to reflect the actual Treasury and LIBOR rates as of the issuance of this decision. Given that we are adopting Staff's formula approach as reasonable, we do not need to rely on Staff's alternative grounds which were based on its observation that Corning has failed to comply with the Commission's Order Authorizing the Issuance of Securities in Case 17-G-0346. However, we do agree with Staff that the Company's failures to promptly disclose the terms of the long-

94 Staff Initial Brief 49.

95 Staff Initial Brief 49-50.

term debts that it issued and to demonstrate the reasonableness of those terms is unacceptable. We expect that the Company will comply going forward and so not require a prudence review.

4. Return on Equity

The largest point of contention surrounds the dispute on the authorized ROE. Corning's requested 10.20% is contrasted with Staff's recommended 8.45%, a difference of approximately $8 million in revenue requirement.[96] Disputed issues involve the composition of appropriate proxy groups, appropriate growth rates for the discounted cash flow ("DCF") analyses, key inputs employed in the capital asset pricing model ("CAPM") analyses, the relative weighting of the CAPM and DCF results, and appropriateness of imputing a size premium. Before we discuss the specific disputes, we note that the Commission's concern is in arriving at a just and reasonable result that balances the needs of the Company to access investment capital with those of the customer that must pay the rates we set.

a. Proxy Groups

A proxy group analysis is used as a guide to reduce the potential for bias and inaccuracy in equity analyst estimates. Selected members of a proxy group should be reasonably comparable to the utility seeking new rates as determined by a set of selection criteria. The elements of such criteria can significantly influence the constituents of a proxy group affecting the final ROE recommendations. Thus, it is important to analyze what criteria has been applied to determine whether those constituent members represent similarly situated utilities.

The Company proposed the use of two proxy groups: a group consisting of a combination of gas and electric utilities;

[96] See Staff Initial Brief 39-40.

and a group consisting of gas only utilities all the members of which were included in the combined group. Staff analyzed only a single group consisting of 33 electric utilities and five natural gas utilities. The two parties agreed on certain criteria for proxy utilities such as each utility maintaining investment-grade credit ratings, not being a party to mergers or acquisitions, and having paid regular dividends. While both parties also evaluated prospective companies to determine how much is earned from regulated operations, Staff measured the amount relative to the companies' revenues while Corning measured their earnings relative to net operating income. Lastly, Corning also included a criterion by which a member could not own generation exceeding 60% of its megawatt-hour ("MWh") sales.[97]

Staff challenged both these differences, noting that the MWh criterion was unreasonably restrictive, and that net operating income created a proxy group that was ultimately much riskier in profile than Corning. On this second point, Staff asserted that inclusion of a riskier, non-utility subsidiary would make it more likely that a subsidiary with poor operating income would be included in the Company's proxy group.[98] Corning defended its exclusion of companies owning significant generation resources as not reflecting a similar risk profile to the Company.[99] Similarly, although Staff contested Corning's use of a gas-only proxy group as being too small, the Company countered that Staff's proxy group consisting of 85% electric utilities does not appropriately reflect the risks associated

97 Staff Initial Brief 51-53.

98 Staff Initial Brief 54.

99 Corning Reply Brief 48-49.

with Corning's gas-only distribution operations.[100] Having reviewed the points raised by both parties, we opt to rely on Staff's proxy group as reasonable.

b. Discounted Cash Flow

As Staff notes, the primary challenge in applying the DCF is determining the rate of growth in future dividends that investors expect. Although Staff contested As Staff contends, the Company's DCF models contain inputs that are problematic and some of which the Commission has rejected in past rate matters.

Staff reasonably demonstrates that Corning's use of earnings growth forecasts rather than dividend growth forecasts for the short-term growth rates is not supported by the record and is of questionable validity at best.[101] The Commission has never endorsed a DCF formula that substitutes earnings growth for dividend growth and we do not see anything in the Company's submittals that would make us inclined to endorse it now. We agree with Staff that the assumption is problematic in that it does not serve to measures the present value of future dividends as intended by the DCF.

Additionally, we agree that Corning's long-term growth rate GDP growth rate derived from forecasted inflation rates and historic real economic growth rates is excessive. Staff demonstrates that the use of historic growth rates creates issues where, as here, there is no demonstration that circumstances for the historic period are adequately similar to current economic conditions and likely to provide an accurate forecast for future growth. In particular, we find compelling Staff's illustration that the Company's historically derived long-term growth rate of 5.52% exceeds the forward-looking GDP

[100] Corning Initial Brief 62.

[101] See Staff Initial Brief 57-58.

estimate of 4.00%, published by Blue Chip Economic Indicators, by 152 basis points, while Staff's long-term growth rate of 4.70% exceeds this forward-looking GDP growth forecast by 70 basis points.[102] From this observation, it is clear that the Company's projection is very likely an outlier and of questionable reliability. Lastly, the Commission has already rejected the arguments raised by Corning regarding the timing of future dividend payments and the effect of the time value of money in Case 08-E-0539.[103] On the record before us, we see no reason to revisit that determination as nothing new has been raised in this case. The Commission's observation there that any additional allowance in the Company's ROE based on adjustments for the timing of dividends would be duplicative for those who actually reinvest dividends and unnecessarily generous to those who do not still applies. Thus, consistent with the Commission's 2008 Con Edison Rate Order, we decline to apply an upward adjustment to Staff's DCF results on which our ROE decision here is based.

c. Capital Asset Pricing Model

Both Corning and Staff calculated CAPM results for their respective proxy groups using a traditional and a zero-beta methodology. The parties differ, however, on the inputs used. Specifically, Staff takes issue with three facets of the Company's analysis arguing that Corning used an excessive market-return estimate of 14.27%, used a flawed source for its beta input, and used inappropriate risk-free rates.[104]

Regarding the Company's 14.27% market rate of return

[102] Staff Initial Brief 59-60.

[103] See Case 08-E-0539, Consolidated Edison Company of New York, Inc. – Electric Rates, Order Setting Electric Rates 125-126 (issued April 24, 2009) (2008 Con Edison Rate Order).

[104] Staff Initial Brief 63-66.

estimate, relying on language from a Federal Energy Regulatory Commission order, Corning omits the use of a long-term component in its methodology relying wholly on a constant growth analysis of the S&P 500 index derived from short-term earnings. Staff challenges the Company's methodology stating that it is unreasonable to assume that near-term earnings growth forecasts formulated for the next three to six years will last into perpetuity. Additionally, Staff dismisses Corning's use of a beta from Bloomberg noting that the Commission has consistently used Value Line betas based on research that demonstrates the superiority of those betas. Nothing was presented in this case to make us reconsider that use in favor of other beta sources, or even as additional beta sources. We also agree with Staff that a five-year measurement period for beta balances the interests of having a long enough timeframe to produce reliable estimates but using recent enough data to reflect current market conditions. Lastly, we agree with Staff that the best forecast of future interest rates is a no-change forecast. There is no credible evidence that forecasts of changes in interest rates are reliable not just in terms of the amount of a predicted change, but even in the direction of any such change. Accordingly, we affirm the Commission's practice of not relying on any published analysts' interest rate forecasts to determine the risk-free rate, but rather to assume a no-change forecast.

Corning challenges Staff's CAPM result as being too low attributing such result to Staff's exclusive use of Value-Line betas,[105] but a review of the record demonstrates that the Staff methodology used follows Commission precedent as reflected in the rate case decisions that have been issued since the

[105] Corning Initial Brief 62.

Generic Finance Recommended Decision.[106] We agree with Staff and will employ its CAPM as updated.

As the Commission did in Case 16-G-0257 when it considered the litigated record to establish rates for National Fuel Gas, we rely on certain longstanding elements of the Commission's finance methodology: the application of both DCF and CAPM analyses to a representative proxy group of utility companies; the use of a two-stage DCF computation with inputs derived from Value Line; the basing of CAPM results on an average of the outcome from standard and zero-beta models with a risk-free rate based on Treasury bonds, market risk premium provided by Merrill Lynch's Quantitative Profiles, and betas taken from Value Line.

d. DCF/CAPM Weighting

The Commission has expressed its preference for a two-thirds weight of the DCF and a one-third weight to the CAPM results on numerous occasions. Relying on more observable and less subjective inputs, the DCF is superior to the CAPM and our preferred weighting for determining an ultimate ROE recognizes that superiority of the DCF. As Staff discusses in its brief, Corning's issues with the differences between the Company's own CAPM and DCF results are products of questionable inputs that we have rejected in this Order. Were the Company to run their respective calculations using our adopted inputs, it is more than likely that the two results would be more closely aligned. In any event, we see nothing new raised that has not been considered and rejected in past Commission orders on the question of weighting the two methodologies and affirm its use herein.

---

[106] Case 91-M-0509, Proceeding on Motion of the Commission to Consider Financial and Regulatory Policies for New York State Utilities, Recommended Decision (issued July 19, 1994).

e. Size Premium

As a final issue, Corning urges the Commission to employ a 50-basis point upward adjustment to our final ROE to account for Corning's small size relative to some other New York investor-owned gas utilities.[107] The Company claims that such an adjustment is warranted because its smaller size makes it less able to weather events that adversely impact its revenues and expenses creating additional risk that should be compensated. In the universe of regulated utilities, difficulties faced by other smaller-sized companies are not present for precisely the reasons cited by Staff, e.g., they are heavily regulated and follow similar accounting procedures to each other, they are required to seek regulatory approval for security issuances, and they are provided just and reasonable rates that can be changed upon a demonstration of inadequacy. Thus, we see no reason based on size-alone to provide a premium to the Company's allowed ROE.

Here, we have already declined to apply numerous inputs used by Corning underlying its requested 10.20% ROE. In doing so, we have affirmed past Commission precedent and decided to apply Staff's application of the Commission's generic finance methodology. In so doing, we are allowing the Company to set rates based on an 8.80% ROE which has been updated from the time of Staff's testimony to reflect the most current financial information available. This result is the product of a rational methodology that creates predictability and certainty and balances all interests involved. As such, our allowed ROE and the other cost of money issues resolved in this section contribute significantly to the rate plan included in this Order and our finding that the rates we are setting are, as a whole,

[107] Corning Initial Brief 65-66.

just and reasonable.

F. Overall Revenue Requirement

All the changes discussed above result in a base rate decrease of $0.766 million. As previously stated, a $1.3 million tax surcredit is expiring and the DRA surcharge is forecast to be reduced by $30,000. These changes result in a total net revenue impact of $505,000, which is an overall revenue increase of 1.77% over the Rate Year. The average annual bill impact on residential customers will be an increase of approximately 2.43% and the average annual bill impact on low income customers will be a decrease of approximately 6.14%. However, as new rates will not go into effect until June 1, 2021, these impacts will need to be compressed into the remaining eight months of the Rate Year. To effectuate this compression, the Company must institute a surcharge, allocated to all service classes based on revenues excluding contract customers, that will collect $311,501 from June 1, 2021, through the end of the Rate Year. The amount is comprised of: 1) the tax sur-credit passed back between February 1, 2021, and May 31, 2021; 2) the residential base revenue decrease that the Company should have implemented beginning February 1, 2021, through May 31, 2021; and 3) the non-residential base revenue decrease that the Company should have implemented beginning February 1, 2021, through May 31, 2021. This surcharge shall expire on January 31, 2022. The Company shall reconcile the amounts collected through the compression surcharge to the amounts that should have been collected if rates had gone into effect on February 1, 2021. The residential base revenue collected through the compression surcharge shall not be included in this reconciliation as it will be reflected in the RDM reconciliation. The reconciliation amount shall be booked

to a regulatory asset or liability account, dependent upon the result of the calculation, for the Commission's future determination.

G. Gas Safety

Staff and the Company are mostly in agreement with the revenue adjustment programs applicable to its gas safety initiatives. These initiatives establish safety performance targets in the areas of Leak Management, Infrastructure Enhancement, Emergency Response, Damage Prevention, and Non-compliance with the Commission's Gas Safety Regulations.[108]

Consistent with other gas utilities, Corning's performance is subject to a maximum negative revenue adjustment of 150 basis points for unsatisfactory performance.[109] The parties agree both to the total amount of revenue exposure and as to how the allocation of those points should be made. Corning also has some metrics by which it can earn positive revenue adjustments. There are some minor differences between the parties as to how to measure performance in certain targets and as to the amount and eligibility for positive adjustments.

As of the end of 2019, Corning's system included approximately 70 miles of leak prone pipe remaining to be replaced. The parties have agreed on requiring the Company to replace ten miles per year, which puts Corning on track to conclude its replacement program in approximately seven years. The parties also agree to a target of replacing a minimum of 250 leak prone services per year, concurrently with the main replacement program, and that all gas meters and service regulators be placed outside a customer's building or structure

[108] See Appendix 7 for a full description of all metrics and programs.

[109] Staff Initial Brief 81-82.

on all new and replacement service installations. The parties also agree that any leaks that Corning need repair in a flood control area may be included as part of the leak prone pipe replacement program. This allowance is for the period addressed in this rate proceeding and may not be extended, explaining that to remove and avoid conflicts with the flood control levees that currently contain leak prone pipe with active leaks, if the length of the pipe required to be replaced or relocated is longer than the actual length of the pipe in the ditch, Corning will be allowed to count the entire length of the pipe installed towards its annual 10 mile replacement target.[110] There is additional agreement on the treatment of incremental costs over the $33.96 cost per foot for systematic replacement of distribution main in calendar year 2021 utilized by the Staff Infrastructure and Operations Panel to calculate the average unit cost and on the maintaining of records of the number of miles and feet of main replaced, specifically in the flood control area.[111] Finally, the parties also agree that Corning be subject to a maximum negative revenue adjustment of 15 basis points[112] for not meeting its targets.[113]

There is one area of dispute as to whether Corning should be provided with a positive revenue adjustment for exceeding its annual leak prone pipe replacement targets.[114] The Company raised this possibility for the first time in rebuttal preventing Staff from addressing it in testimony. In brief, however, Staff does not recommend we adopt any positive

---

110 Staff Initial Brief 82-83.

111 Staff Initial Brief 83.

112 All basis points applicable to negative revenue adjustments in this section are assessed on a pre-tax basis.

113 Staff Initial Brief 83.

114 Corning Initial Brief 70-71.

adjustment mechanism for leak prone pipe replacement. Staff relies mostly on its agreement with Corning that allows it to count additional pipe replacement in flood control areas towards its annual replacement goal. Staff notes that this allowance already provides an incentive to the Company and allow it to easily achieve its annual target.[115] We agree and decline to adopt a positive rate adjustment in this particular instance.

For leaks on the Company's system, Corning and Staff agree to total leak backlog targets of 45 at the end of 2021 and 40 at the end of 2022. The Company and Staff also agree for Corning to meet a repairable leak backlog of four leaks or fewer until changed by the Commission. As for an assessed revenue adjustment, Corning agrees to Staff's recommendation of five basis points for the total leak backlog target and ten basis points for the repairable leak backlog target.[116] Again, the two parties disagree on the application of positive revenue adjustments, although in this case they agree that some program of positive adjustments should be included in the rate order.

Staff proposes a tiered approach such that two basis points would be awarded for total year-end leaks between 34 and 26, four basis points for total year-end leaks between 25 and 16, and six basis points for fewer than 16. Corning contests the fairness of increasing the risk attached to potential negative revenue adjustments while reducing the additional earnings attached to superior performance.[117] Corning proposes that the respective tiers be valued at four, six and eight basis points, respectively.[118] Staff notes that its recommended

[115] Staff Initial Brief 83-84.

[116] Staff Initial Brief 84.

[117] Staff Initial Brief 84-85.

[118] Corning Initial Brief 70.

positive revenue adjustment amounts are commensurate to other New York gas utilities.[119] Corning's fairness argument is tied to the fact that Staff's recommendation has reduced the revenues available to it under its previous rate plan. However, the Company does not dispute Staff's representation regarding similarly situated gas utilities. Accordingly, we adopt Staff's recommendation.

For Damage Prevention, Staff and Corning agree that its existing categorized program be converted into one metric applicable to total damages assessed on a tiered basis.[120] However, the parties disagree on the maximum exposure to which the Company should be subject. Under Staff's recommended program, for the maximum exposure tier, the target is set at a rate in excess of 2.50 damage incidents per 1000 one call tickets with an associated negative revenue adjustment of 20 basis points. For the second tier, the applicable target is between 2.26 and 2.50 incidents per 1000 one call tickets with an associated negative revenue adjustment of ten basis points. For the third tier, the applicable target is between 2.01 and 2.25 incidents per 1000 one call tickets with an associated negative revenue adjustment of five basis points. After a neutral tier whereby no revenue adjustment is made for performance within 1.51 and 2.00 incidents per 1000 one call tickets, the Company would begin to realize a positive revenue adjustment of five basis points for performance within 1.26 and 1.50 incidents, and ten basis points for a rate below 1.26 incidents.[121]

Corning argues that 20 basis points is too high and

[119] Staff Initial Brief 85.

[120] Corning Initial Brief 73.

[121] Staff Initial Brief 85-86.

proposes a maximum exposure of fifteen basis points. The Company relies on its small size asserting that any change in the number of total damages results in a large impact on its overall damage performance.[122] Staff does not specifically respond to Corning's assertion, but instead observes that when measured against the 2019 statewide average, Corning's performance for overall damages was at a rate of 2.10 per 1000 one-call tickets, worse than the average statewide performance level of 1.84 per 1000 one-call tickets of other gas utilities. Citing to the Company's historic performance, Staff asserts that its recommendation is designed to bring Corning closer to the statewide average.[123] We share Staff's concern regarding the Company's standing vis-à-vis its peer utilities. Accordingly, we adopt Staff's recommended exposure levels, as well as its positive incentive levels to which Corning did not object.

For Corning's emergency response program, Staff and the Company agree to maintain the current targets which require Corning to respond within 30 minutes to 75% of all gas leak, odor, and emergency calls; respond within 45 minutes to 90% of all gas leak, odor, and emergency calls, and respond within 60 minutes to 95% of all gas leak, odor, and emergency calls.[124] Staff has recommended an increase in the maximum exposure applicable to these tiers to twelve, eight, and five from the Company's last rate plan which applied six, four and two, respectively. Staff posits that such an increase will provide an incentive for Corning not to backslide from its current performance which was compliant.[125] Corning counters that there

[122] Corning Initial Brief 73.

[123] Staff Initial Brief 86.

[124] Staff Initial Brief 86-87.

[125] Staff Initial Brief 87.

is no reason to believe that the Company's performance will decrease.[126] Although we agree with Staff's recommended increase in exposure, we think the more compelling reason to do so than Staff's backsliding prevention concern is because such an increase better reflects the Commission's elevated concern with the importance of responding to an emergency situation, particularly in the context of retaining a 150 basis point total maximum exposure, but reallocating that exposure among the complete profile of Corning's gas safety programs.

Finally, for the outcomes of field audits performed by the Department's Gas Pipeline Safety Staff to determine compliance with the Commission's pipeline safety rules and regulations contained in 16 NYCRR Parts 255, 261 and 753, Corning and Staff are in agreement across the program. As an initial matter, for violations that occurred in previous years, Corning owes to customers $153,000 of which the parties to propose to invest $75,000 in the implementation of a Residential Methane Detector Program.[127] We agree.

As to the specifics of violations of the Commission's rules and regulations, the parties agree on a negative revenue adjustment maximum exposure of 75 basis points per year, which is consistent with the pipeline safety performance measure metrics for other New York gas utilities.[128] The 75 basis points would be assessed as follows: for record audits, the first five high risk violations would not subject the Company to any adjustment; from the sixth to the 20th high-risk violations, the Company would incur one-half basis point per violation; and for each high-risk violation greater than 20, the Company would

---

[126] Corning Initial Brief 73.

[127] Staff Initial Brief 88, 94-95; Corning Initial Brief 75-76.

[128] Corning Initial Brief 73.

incur one basis point per violation. For the first 15 other risk violations, the Company would not be subject to an adjustment; and for each other risk violation greater than 15, the Company would incur a negative revenue adjustment of one-fourth of a basis point per violation. For field audits and investigations, the Company would incur a negative revenue adjustment of one-half a basis point for each of the first 20 high-risk violations; for each high-risk violation in excess of 20, the Company would incur a negative revenue adjustment of one basis point per violation; and for all other risk violations, the Company would incur a negative revenue adjustment of one-fourth basis point. In addition, for each audit year, a cap on the total record audit violation count of ten basis points will apply to each of the code sections identified in Hearing Exhibit 44 which lists several discrete code sections, with any additional noncompliance of those sections subject to further review and action. As explained by Staff, in any case where the Company has more than ten violations of a single code section, the Company is to develop a corrective action plan to ensure that violations do not continue and should the Company fail to comply with its corrective action plan, the number of violations of a given code section that are in excess of ten would be included with the remainder of the violations being considered for the compliance measure, thereby increasing the basis points at risk in a potential negative revenue adjustment. While the corrective action plan is intended to avoid the need for formal, intensive penalty actions against the Company for each noncompliance, it does not replace the Commission’s ability to pursue a penalty action should the need for such action become apparent so as to compel compliance.[129]

[129] Staff Initial Brief 88-90.

H. Customer Service and Low Income

Since 2017, the Commission has been working with Office of Consumer Services to bring consistency across the State's utilities to their Customer Service Performance Indicator (CSPI) programs, including consolidating the names of the different metrics as well as the timing of annual reporting. We continue that trend and adopt Staff's general recommendations, to which the Company agrees, as to the names and applicability of the various metrics, the requirement that Corning's annual performance review be done on a calendar year basis, and to apply negative revenue adjustments for each metric that are measured in terms of pre-tax basis points rather than specific dollar amounts.[130]

The Company and Staff agree to maintain the current target level of three or fewer customer complaints to avoid a negative revenue adjustment.[131] Additionally, the Company and Staff agree to a Customer Satisfaction Survey minimum score of 87.7% to avoid a negative revenue adjustment. Should its score fall between 86.7% and less than or equal to 87.7%, Corning would be subject to a five-basis point adjustment, ten basis points for a score between 85.7% and less than 86.7%, and fifteen basis points for a score less than 85.7%.[132]

For Appointments Kept, Corning agrees to Staff's recommendation at this time to develop written policies and procedures for scheduling, logging, tracking and verification of service appointments and missed appointment information. Corning also will inform customers that they will receive a $25 credit for a missed appointment either at the time the

130 Corning Initial Brief 78.

131 Staff Initial Brief 98.

132 Staff Initial Brief 98-99.

appointment is made or when confirming the scheduled appointment.[133] Corning should file its proposed policies and procedures with the Secretary within 30 days after issuance of this Order.

While the parties have agreed that Corning will add an Arrearage component to its existing Residential Service Terminations and Uncollectibles metric, Staff and the Company disagree on the targets that would be applied and the associated positive and negative revenue adjustments that would be applied against performance.[134] We, however, will pause this mechanism because, on May 11, 2021, Governor Cuomo signed into law an extension to the moratorium on utility terminations for residential and small businesses for a period of 180 days after the COVID-19 state of emergency is lifted or 180 days after December 31, 2021, whichever is earlier. The moratorium may be in effect much of the Company's rate year, which will impact company operations. Corning's actual termination, arrearage and uncollectible performances will be impacted by the legislation and its performance will not be comparable to either Staff or the Company's proposed performance targets. Staff, the Company and parties can explore reinstating this mechanism in the Company's next rate filing.[135]

The parties are also in agreement that the Company will file a feasibility proposal for an Electronic Deferred Payment Agreements (e-DPA) program.[136] We take no further action on this item, noting that only a proposal is required here. Thus, issues raised by Coring as to its Customer Information

[133] Corning Initial Brief 79.

[134] Corning Initial Brief 79.

[135] See Appendix 8 for the CSPI metrics.

[136] Corning Initial Brief 82.

System not being connected to the Company web page for a secure portal for signatures and any alternatives may be raised in the filed proposal. The parties also agree as to securing support for its Customer Information System. Corning's proposal should be included in the Company's next rate filing, unless such filing is not made within 60 days after issuance of this Order, in which case the proposal should be filed within the same 60 days as a stand-alone compliance item.

Lastly, Corning agrees with Staff's recommendations to increase the existing low-income discount from $8.00 to $16.00 per month and its overall Low-Income Program budget to $250,000.[137]

I. Rate Design Issues

1. Embedded Cost of Service Study

The Company provided an embedded cost of service studay ("ECOS Study") allocating the Company's revenues and expenses to each service class. The ECOS study calculated a rate of return by class for guidance in revenue allocation and rate design, and allocated costs between customer-related (exclusive of demand) and demand-related costs. The ECOS Study classified gas distribution main costs as customer-related on the basis of a minimum system study, a 2-inch main system that would be required without consideration of any demand.[138]

Staff criticized the minimum system study on the basis that the five years of data on 2-inch mains were limited and not reflective of the Company's entire system cost. Staff recommends that the Company use in future cases the average installation cost for 2-inch mains based on the Company's entire

[137] Corning Initial Brief 83.

[138] Tr. 279-289.

plant in service, not just the last five years of costs. Staff further proposes that if the relevant data are unavailable, the Company usea state-wide average customer componenet of the minimum system study to allocate distribution main costs.[139] The Company responded in rebuttal testimony that only a few years of data are necessary for this calculation and that a state-wide average would be meaningless.[140]

Because we are not using the ECOS study to design rates in this case, we do not need to resolve this issue here. We urge the Company to work with Staff prior to filing its next rate case to reach a mutual agreement on the data to use for the minimum system study. If agreement is not reached, we expect to see testimony on this matter in the next case, and we will address the issue at that time.

Multiple Intervenors objects to the Company's use of an "adjusted customer allocation factor" to allocate the costs of mains larger than two inches as this underallocates costs to small customers by attempting to combine the number of customers with the aggregation of larger loads. Multiple Intervenors witness Baudino testified that the Company's adjusted customer allocation factor was highly unusual.[141] The Company took issue with Mr. Baudino's illustrative alternative calculation but did not directly address Mr. Baudino's objections to the adjusted customer allocation factor.[142]

We see merit in Multiple Intervenors' objections to the adjusted customer allocation factor, but because we are not using the ECOS study for rate design in this case, this issue

[139] Tr. 1018-1020.

[140] Tr. 311-313.

[141] Tr. 882-885.

[142] Tr. 314.

can be addressed if necessary in the Company's next rate case.

2. Revenue Allocation

Because of the unresolved disputes about the details of the ECOS study and because the revenue requirement increase we are authorizing in this case is relatively small, we will allocate the revenue requirement increase to each class of service on a uniform basis as proposed by the Company[143] with one exception: we will allocate a slightly larger increase to SC 8 Hamondsport Transportation to move it closer to SC 6 Commercial Transportation, which has similar characteristics. This adjustment was recommended by Staff[144] and not contested by the Company.[145] UIU also concurs with a uniform increase as adjusted by Staff.[146] Multiple Intervenors objects to a uniform rate increase and proposes adjustments to rate design based on the ECOS study,[147] but given the multiple criticisms of the ECOS study and the small revenue increase allowed in this case, we will adopt Staff's position.

3. Rate Design

The Company proposed increases in minimum charges of appproximately 25%.[148] Staff proposed proportional increases across the board to minimum customer charges and all other volumetric charges based on the revenue requirement authorized in this case.[149] The Company accepted Staff's proposal in its Reply Brief.[150] We accept the agreement of the parties. The

[143] Company Reply Brief at 75.

[149] Hearing Exh. 46 (SRP-4); Staff Initial Brief at 79.
[150] Company Reply Brief at 76.

final revenue allocation is contained in Appendix 9.

4. Lost and Unaccounted for Gas

For the last two rate proceedings, the Company has operated under an incentive mechanism for Lost and Unaccounted for ("LAUF") gas, which is calculated by subtracting metered deliveries from metered supplies. The mechanism is based on a LAUF Factor of Adjustment, which contains a deadband above which the Company incurs a penalty, and below which the Company achieves an incentive. Within the deadband the Company recovers its actual commodity costs. The current Factor of Adjustment is 1.0037, and the deadband is from 1.0 to 1.0160. The Company recommended no change in these amounts. Staff proposed to reset the Factor of Adjustment to 1.0027 based on the most recent five year period as the Commission did in the last two rate cases, and to reset the deadband at 1.0 to 1.0192.[151] The Company accepted these adjustments in its Reply Brief,[152] and we accept the agreement of the parties.

V. CONCLUSION

We find that the rates and rate plan adopted herein provide just and reasonable rates, terms and conditions, and, consistent with the discussion herein, are in the public interest.

The Commission orders:

1. Corning Natural Gas Corporation is directed to file cancellation supplements, effective on not less than one day's notice, on or before May 26, 2021, cancelling the tariff amendments and supplements listed in Appendix 1 to this Order.

---

[151] Tr. 1031-1032.

[152] Company Reply Brief at 76.

2. Corning Natural Gas Corporation is directed to file, on not less than five days' notice, such further tariff revisions as are necessary to effectuate the provisions adopted by this Order, including a total net revenue increase of $505,000 to take effect June 1, 2021, as detailed in Appendix 2 to this Order. Corning Natural Gas Corporation shall serve copies of its filing on all active parties in these cases. Any comments on the compliance filing must be received at the Commission's offices within 14 days of service. The amendments specified in the compliance filing shall not become effective on a permanent basis until approved by the Commission.

3. The requirement of Section 66(12)(b) of the Public Service Law that newspaper publication be completed prior to the effective date of the proposed amendments directed in Clause 2 above is waived and Corning Natural Gas Corporation is directed to file with the Commission, not later than six weeks following the amendments' effective date, proof that a notice to the public of the changes made by the amendments has been published once a week for four successive weeks in newspapers having general circulation in the areas affected by the amendments.

4. Corning Natural Gas Corporation is directed to file within 90 days after the end of each calendar year, beginning with 2021, capital expense and variance reports as described in the body of this Order.

5. The Petition of Corning Natural Gas Corporation to Defer Leak Survey and Repair Costs Over and Above the Level Last Established in Rates in Case 16-G-0204 is denied.

6. Corning Natural Gas Corporation shall, within 30 days of the date of issuance of this Order, file proposed policies and procedures with respect to missed appointments and a customer credit of $25 for missed appointments.

7. Corning Natural Gas Corporation shall, either in its next rate case filing or within 60 days of the issuance of this Order, whichever first occurs, file a proposal for an electronic deferred payment agreements program.

8. These proceedings are continued.

By the Commission,

(SIGNED) MICHELLE L. PHILLIPS
Secretary

Summary of Adjustments
For the Rate Year Ending January 31, 2022

Adj No.	Description of Adjustment	Commission Adjustments	Total Amount
Adj. 1	**Operations and Maintenance**		
A.	**Direct Labor**		
(1)	To eliminate management wage increases	(5,139)	
(2)	To update overtime pay for union contract	3,258	
(3)	To update vacation pay for union contract	2,557	
(4)	To reflect union wage increases of 3%	18,923	
(5)	To remove allowance for four new hires	(169,780)	(150,181)
B.	**Insurance**		
(1)	To reduce health insurance related to removal of four hires	(77,680)	
(2)	To reduce dental insurance related to removal of four hires	(5,251)	(82,931)
C.	**Regulatory**		
(1)	To reflect amortization of Prior Period OPEB deferral over 3 years	(38,608)	
(2)	To reflect amortization of 2016, 2017, 2018 NRAs deferral over 3 years	(11,749)	
(3)	To reflect amortization of new 2019 NRA deferral over 3 years	(804)	
(4)	To reflect amortization of 2016 NRA deferral over 3 years	(3,137)	
(5)	To reflect amortization of 2017 NRA deferral over 3 years	(2,447)	
(6)	To reflect amortization of 2018 NRA deferral over 3 years	(11,945)	
(7)	To reflect amortization of Gas Supply Specialist deferral over 3 years	2,221	
(8)	To reflect amortization of Net Plant deferral over 3 years	13,674	
(9)	To reflect amortization of 2016 Rate Case deferral over 10 years	(82,333)	
(10)	To reflect amortization of Fixed Interest deferral over 10 years	(59,781)	
(11)	To reflect amortization of Customer Incentive deferral over 10 years	(6,400)	
(12)	years	(14,686)	
(13)	To reflect amortization of Customer Affiliate Allocation Shortfall deferral over 10 years	(8,778)	
(14)	To reflect amortization of Customer Make Whole Increase deferral over 10 years	(9,198)	
(15)	To reflect amortization of Rate Case 2020 deferral over 10 years	(148,377)	
(16)	To include leak backlog, total damages and mismarks NRA deferrals for 2016, 2017 and 2018	(17,623)	
(17)	To include updated NRA balance	(14,520)	
(18)	To include removal of Company's 2019 NRA deferral estimate	10,000	
(19)	To include 2019 mismark NRA deferral	(1,207)	(405,698)
D.	**Pension-Amortization**		
(1)	To reflect amortization of pension deferral over 10 years		(111,318)
E.	**OPEB-Amortization**		
(1)	To reflect amortization of OPEB deferral over 10 years		36,313
F.	**Debit Card & Credit Card Fees**		
(1)	To update estimated vendor costs		8,242
G.	**Outside Services**		
(1)	To remove allowance for the IT consultant		(72,000)
H.	**Other O&M**		
(1)	To update for the latest construction overhead rate		80,369
	Total O&M Expense Adjustments		(697,204)
Adj. 2	**Depreciation Expense**		
(1)	To reflect correction to depreciation expense	(119,845)	
(2)	To remove the allowance for accelerated depreciation of leak prone pipe	(414,213)	(534,058)
Adj. 3	**Taxes Other Income Taxes**		
A.	**Payroll Tax**		
(1)	To track labor adjustments		(15,303)
	Total Taxes other than Income Tax Adjustments		(15,303)

Adj. 4	**New York State Income Tax**		
A.	**Deferred Taxes**		
(1)	To track deferral adjustments		26,370
Adj. 5	**FED Income Tax**		
A.	**Deferred Taxes**		
(1)	To track deferral adjustments		31,511
Adj. 6	**Rate Base**		
A.	**Net Utility Plant**		
(1)	To correct for errors in Company's plant model		104,242
B.	**Plant Reserves**		
(1)	To reflect correction to accumulated depreciation	46,091	
(2)	To remove the allowance for accelerated depreciation of leak prone pipe	207,106	253,197
C.	**Cash Working Capital**		
(1)	To track adjustment to working capital		(27,063)
D.	**Deferred Debits**		
(1)	To reflect amortization of 2016 Rate Case deferral over 10 years	41,027	
(2)	To reflect amortization of Fixed Interest deferral over 10 years	29,890	
(3)	To reflect amortization of Customer Incentive deferral over 10 years	3,200	
(4)	years	7,343	
(5)	To reflect amortization of Customer Affiliate Allocation Shortfall deferral over 10 years	4,389	
(6)	To reflect amortization of Customer Make Whole Increase deferral over 10 years	4,600	
(7)	To reflect amortization of Rate Case 2020 deferral over 10 years	74,188	164,637
E.	**Deferred Credits**		
(1)	To reflect amortization of Prior Period OPEB deferral over 3 years	19,304	
(2)	To reflect amortization of 2016, 2017, 2018 NRAs deferral over 3 years	5,875	
(3)	To reflect amortization of new 2019 NRA deferral over 3 years	403	
(4)	To reflect amortization of 2016 NRA deferral over 3 years	1,568	
(5)	To reflect amortization of 2017 NRA deferral over 3 years	1,224	
(6)	To reflect amortization of 2018 NRA deferral over 3 years	5,972	
(7)	To reflect amortization of Gas Supply Specialist deferral over 3 years	(1,110)	
(8)	To reflect amortization of Net Plant deferral over 3 years	(6,837)	
(9)	To include leak backlog, total damages and mismarks NRA deferrals for 2016, 2017 and 2018	(79,304)	
(10)	To include updated NRA balance	(65,341)	
(11)	To include removal of Company's 2019 NRA deferral estimate	45,000	
(12)	To include 2019 mismark NRA deferral	(5,431)	(78,677)
F.	**Deferred Taxes Amount**		
(1)	To reflect the ADSIT impact related to the depreciation adjustments	17,357	
(2)	To reflect the ADFIT impact related to the depreciation adjustments	56,076	
(3)	To reflect amortization of Prior Period OPEB deferral over 3 years	(5,309)	
(4)	To reflect amortization of 2016, 2017, 2018 NRAs deferral over 3 years	(1,615)	
(5)	To reflect amortization of new 2019 NRA deferral over 3 years	(110)	
(6)	To reflect amortization of 2016 NRA deferral over 3 years	(431)	
(7)	To reflect amortization of 2017 NRA deferral over 3 years	(336)	
(8)	To reflect amortization of 2018 NRA deferral over 3 years	(1,642)	
(9)	To reflect amortization of Gas Supply Specialist deferral over 3 years	305	
(10)	To reflect amortization of Net Plant deferral over 3 years	1,880	
(11)	To reflect amortization of 2016 Rate Case deferral over 10 years	(11,282)	
(12)	To reflect amortization of Fixed Interest deferral over 10 years	(8,220)	
(13)	To reflect amortization of Customer Incentive deferral over 10 years	(880)	
(14)	years	(2,019)	
(15)	To reflect amortization of Customer Affiliate Allocation Shortfall deferral over 10 years	(1,207)	
(16)	To reflect amortization of Customer Make Whole Increase deferral over 10 years	(1,265)	
(17)	To reflect amortization of Rate Case 2020 deferral over 10 years	(20,401)	
(18)	To include leak backlog, total damages and mismarks NRA deferrals for 2016, 2017 and 2018	21,808	
(19)	To include updated NRA balance	17,969	
(20)	To include removal of Company's 2019 NRA deferral estimate	(12,375)	
(21)	To include 2019 mismark NRA deferral	1,493	49,796

Appendix 3
Schedule 1
Page 1 of 1

Corning Natural Gas Corporation
Deferred Debits and Credits
For the Rate Year Ending January 31, 2022

Deferred Debits

	Balance as of 9/30/19	Number of Years of Amortization	Amortization Expense
Fixed Interest	$ 597,803	10	$ (59,780)
Customer Incentive	64,000	10	(6,400)
Safety & Reliability Shortfall	146,859	10	(14,686)
Customer Affiliate Allocation Shortfall	87,785	10	(8,779)
Customer Make Whole Increase	91,987	10	(9,199)
Rate Case 2020	635,900	10	(63,590)
Rate Case 2016	126,667	10	(12,667)
Total Deferred Debits	**$ 1,751,002**		**$ (175,099)**
Pension Deferral	**$ 1,113,185**		**$ (111,319)**
Total Amortization Expense			***$ (286,418)***

Deferred Credits

	Balance as of 9/30/19	Number of Years of Amortization	Amortization Expense
Prior Period OPEB Interest Due Customers	$ (289,558)	3	$ 96,519
Amortization of Gas Specialist Wage Differential	(5,329)	3	1,776
Deferred Net Plant Due	(32,850)	3	10,950
Deferred Credits-2016 Regulatory Liability	(23,522)	3	7,841
Deferred Credits-2017 Regulatory Liability	(18,355)	3	6,118
Deferred Credits-2018. Regulatory Liability	(89,587)	3	29,862
Deferred Credits-2019 Regulatory Liability	(6,034)	3	2,011
Additional 2016 - 2018 NRAs	(88,115)	3	29,372
Total Deferred Credits	**$ (553,350)**		**$ 184,450**
OPEB Deferral	**$ (363,130)**	10	**$ 36,313**
Total Amortization Expense			***$ 220,763***

Corning Natural Gas Corporation (Corning) Case 20-G-101 Gas Safety Metrics Appendix

Gas Safety Metric	Staff recommendation	CNG Counteroffer
Leak Management	- Reducing the number from five to four leaks at year end. - An NRA of ten basis points for failure to meet the repairable leak target, and five basis points for failure to meet the total leak backlog targets. - If the Company maintains less than 35 total leaks, but not less than 26 total leaks at calendar years-end, it would earn a PRA of two BPs. If the Company maintains less than 25 total leaks, but not less than 16 total leaks at calendar year's end, it would earn a PRA of four BPs. If the Company maintains 15 or less total leaks at calendar year's-end, it would earn a PRA of six BPs. If the Company maintains 15 or less total leaks at calendar year's-end, it would earn a PRA of eight BPs - The Commission should not provide a PRA for Type 3 leaks in its determination of the rate case.	- Corning proposes and Staff agrees to a more stringent target for total leak backlog, by reducing them from 50 to 45 leaks at year-end 2021.
Leak Prone Pipe Replacement	- Corning replace or eliminate a minimum of 10 miles of leak prone pipe (LPP) annually. - Corning replace a minimum of 250 leak prone services per year, concurrently with the main replacement program.	- Corning agrees with Staff's recommended target of ten miles of LPP per year but proposes that LPP include Lines 11 and 15.

Gas Safety Metric	Staff recommendation	CNG Counteroffer
	- All gas meters and service regulators be located outside on all new and replacement service installations. - Corning agrees that it will maintain records of the number of miles and feet of mains replaced, more specifically of the pipe replaced in the flood control area, and any incremental cost over the $33.96 cost per foot for systematic replacement of distribution main in calendar year 2021 utilized by the Staff Infrastructure and Operations Panel to calculate the average unit cost, but no more than 1.5 times cost per unit, be deferred. - The maximum NRA exposure increases to 15 BPs. Corning agrees with Staff's recommendation	- Corning agrees with Staff's recommendation that Corning replace 250 leak prone services per year in conjunction with main replacement. - Corning agrees with Staff's recommendation. Fourth, Staff recommends and Corning supports Staff's recommendation to allow Corning to address the leaks found in the flood control area through the leak prone pipe replacement program.
Damage Prevention	- The total damage target be set at a rate of 2.50 damage incidents per 1000 one call tickets; failure to achieve this target would result in an NRA of 20 BPs; for a rate between 2.26 and 2.50, the Company would incur an NRA of ten basis points; for a rate between 2.01 and 2.25, the Company would incur an NRA of five basis points; for a rate between 1.51 and 2.00, the Company would not incur or earn any revenue adjustments; for a rate between 1.26 and 1.50, the	- Corning proposes and Staff agrees that damages due to mismarks and damages due to Company or Corning Contractor targets be eliminated, and instead Corning should be allowed to maintain an overall damage target. - Corning counter-offered to Staff's

Gas Safety Metric	Staff recommendation	CNG Counteroffer
	Company would earn a PRA of five basis points; for a rate below 1.26 the Company would earn a PRA of ten basis points.	proposed maximum NRA exposure of twenty BPs by proposing a maximum NRA exposure of fifteen BPs, asserting that given the size of the company, a small change in the number of total damages would have a large impact on its overall damage performance.
Violations	- Recommends that of the $153,000 resulting from the negative revenue adjustments, $75,000 be used to fund the implementation of a Residential Methane Detector Program. - Modifying the current NRA BPs allocation by reducing the NRA BPs maximum exposure by 25 BPs, from 100 to 75 BPs per year for this measure. - Violation measure targets and associated NRAs be modified as follows: for record audits, the first five high risk violations would not subject the Company to NRAs; from the sixth to the 20th high-risk violations, the Company would incur one-half BP per violation; and for each high-risk violation greater than 20, the Company would incur one BP per violation. For the first 15 other risk violations, the Company would not	- Corning agrees and accepts Staff's recommendations regarding the violation measure targets and associated NRAs as stated in its testimony.

Gas Safety Metric	Staff recommendation	CNG Counteroffer
	be subject to a NRA; and for each other risk violation greater than 15, the Company would incur a NRA of one-fourth BP per violation. For field audits and investigations, the Company would incur a NRA of one-half BP for each of the first 20 high-risk violations; for each high-risk violation in excess of 20, the Company would incur a NRA of one BP per violation; and for all other risk violations, the Company would incur a NRA of one-fourth BP per violation. - For each audit year, capping the total record audit violation count at ten basis points for each of the code sections identified in Exhibit 44. - If the Company fails to comply with its implementation plan, the number of violations of a given code section that are in excess of ten would be included with the remainder of the violations being considered for the compliance measure. - The performance measure provide a financial disincentive for non-compliance with the pipeline safety regulations, but it addresses only the first ten record audit violations of a specific requirement. If the financial disincentive is insufficient to induce compliance, then additional measures are necessary to change the	

Gas Safety Metric	Staff recommendation	CNG Counteroffer
	performance. It is critical for the Commission to be able to address all violations of its pipeline safety regulations given the potential for serious harm.	
New York State Department of Environmental Conservation requirements and gas leaks found in Flood control area	- Corning be directed by the Commission to seek approval from DEC to perform the necessary work to repair or eliminate these leaks in the flood control area, and file quarterly updates with the Chief of Pipeline Safety and Reliability Section on the status of its work to eliminate or repair the leaks, along with copies of all DEC communications with the Company until all the leaks are eliminated.	- Corning agrees and states that leaks will be addressed through the leak prone pipe replacement program and they will continue to work with the DEC to complete the repairs. - Corning proposes to provide Staff a list of project(s) completed the prior year and those slated to be completed that year, the report will be submitted by January 10th of each year. Staff accepts.
The 1.1 miles of Pipe Located at Sullivan Park Science Center	- Corning perform the necessary operating and maintenance (O&M) work, such as: leak surveys, mark-outs, CP readings, corrosion control/monitoring, identification and inspection of below grade valves, etc. - Within 60 days from the date of Staff filing its direct testimony, the Company files with the Chief of Safety	- Corning states that Staff's recommendation to expect Corning to be able to assure the integrity of the 1.1 miles of pipe within matters of weeks is unrealistic, and that the Company proposes

Gas Safety Metric	Staff recommendation	CNG Counteroffer
	and Reliability Section a report outlining the O&M performed and the records obtained with an explanation of how the integrity of this pipe is guaranteed.	to file the requested report outlining the O&M performed and the records obtained by December 31, 2020.
Residential Methane Detector Program	- Commission direct Corning to develop and file a proposal, within 90 days from the issuance of its rate order, for a Residential Methane Detector pilot program. This proposal will include details on Corning's deployment strategies, the number of customers involved, the number of methane detector units, and the associated cost per unit.	
Training with First Responders and New York Pipeline Emergency Responders Initiative, or NYPERI	- Corning improves its existing training with fire departments and first responders by conducting emergency drills, hands-on activities, and workshops with a review of the processes and procedures that would be used during an emergency. To accommodate this training, we recommend that $78,000 be included in Corning's capital budget for the purpose of establishing a training center so that Corning can conduct fire drills, or for the acquisition of a trailer type vehicle equipped with the necessary equipment to conduct drills and simulate real-life or life like environmental conditions that	- Corning agrees with the necessity of this training and believes that it has an advantage in that its Training Technician is a Chief with a local volunteer department and is a Training Technician with the New York State Fire Training Academy.

Gas Safety Metric	Staff recommendation	CNG Counteroffer
	change similar to situations experienced in the field. - An incentive, a PRA of one BP for each drill conducted up to six BP per year, with the assumption that Department Gas Safety Staff will be invited to attend each drill and that documentation is provided following each drill including a video recording of each drill and a list of all persons taking part. - Implementing emergency drills which will help educate and train those individuals on how to respond prior to an incident. - Corning participates in the collaborative effort with the stakeholders (Natural Gas Local Distribution Companies, Fire Departments, State Fire Marshal, Department of Public Service, etc.) of the NYPERI.	
Monthly Leak Report	- Staff did not address this request in its direct testimony, however, it would not be opposed to the Company's request.	- Corning proposed in its direct and rebuttal testimony that it be allowed to discontinue submitting reports on a monthly basis regarding leak repair status, leak survey status, quantity of leaks discovered, quantity

Gas Safety Metric	Staff recommendation	CNG Counteroffer
		of leaks repaired, and quantity of main, pursuant to Commission order issued in case 05-G-1539.

Customer Service Performan Indicator (CSPI)

STATE OF MICHIGAN

BEFORE THE MICHIGAN PUBLIC SERVICE COMMISSION

In the matter of the application of **CONSUMERS ENERGY COMPANY** for authority to increase its rates for the distribution of natural gas and for other relief.	)))))	Case No. U-21806

REBUTTAL TESTIMONY

OF

JESSICA R. BYROM

ON BEHALF OF

CONSUMERS ENERGY COMPANY

May 2025

Q. Please state your name and business address.

A. My name is Jessica R. Byrom, and my business address is One Energy Plaza, Jackson, MI 49201.

Q. Are you the same Jessica R. Byrom who previously submitted testimony in this case on behalf of Consumers Energy Company ("Consumers Energy" or the "Company")?

A. Yes.

Q. What is the purpose of your rebuttal testimony?

A. The purpose of my rebuttal testimony is to rebut the direct testimony of Michigan Public Service Commission ("MPSC" or the "Commission") Staff ("Staff") witness Brittany Klocke on the topics of the Company's Low and Medium Income ("LMI") Customer Support Enhancement project and its Customer IT and IT Enhancements; Attorney General witness Sebastian Coppola's testimony regarding operating and maintenance ("O&M") for Customer Digital Customer Operations ("DCO") and Analytics and Outreach work, Michigan Environmental Council ("MEC") and Sierra Club ("SC") (collectively "MEC") witness Alice Napolean's testimony that discusses the Company's energy waste reduction ("EWR") programs, and Citizen's Utility Board of Michigan ("CUB") witness Joshua W. Denzler's testimony regarding the Company's Customer Order Service Tracker ("COST") project and associated O&M.

Q. Are you sponsoring any exhibits?

A. Yes. I am sponsoring the following exhibits:

Exhibit A-129 (JRB-4) LMI Mindset Map.

Q. Were these exhibits prepared by you or under your supervision?

A. Yes.

Staff Witness Klocke Regarding LMI

Q. Starting on page 13, line 20 of her testimony, Staff witness Klocke has recommended disallowance of $1.9 million in capital for the Company's Customer-based LMI Customer Support Enhancement project. How does the Company respond?

A. The Company disagrees with Ms. Klocke's assertion that the expenses related to this LMI project are unjustified. 36% of all Consumers Energy customers assume they are not eligible for utility payment assistance, 33% lack awareness of available assistance, and 18% do not know where to start the application process. The project will allow the Company provide assistance to customers in a thoughtful, prescribed manner. Additionally, as an active participant in the MPSC's Low-Income Energy Policy Board, Energy Affordability and Accessibility Collaborative ("EAAC") and EWR Low-Income Workgroup, the Company has planned and executed this project to align with the priorities for assisting LMI customers, responding directly to the EAAC's key area of focus including "strategies for streamlining the energy assistance process; and recommendations on tying energy waste reduction to energy assistance.[1]"

Q. Why is the LMI project's alignment with the MPSC's EAAC and EWR Low-Income Workgroup important?

A. Alignment with the EAAC and EWR Low-Income Workgroup is important because it ensures that this project reflects the needs of the most vulnerable customers and is grounded in best practices developed through statewide collaboration. Parties within these groups represent a broad cross-section of stakeholders, including residents, non-profits, utilities, and state agencies, all holistically working toward assessing energy affordability and

[1] https://www.michigan.gov/mpsc/commission/workgroups/energy-affordability-and-accessibility-collaborative

accessibility, particularly through linking EWR services and energy assistance programs. Their work has produced clear, data-informed recommendations and guiding principles that define what effective, just, and sustainable energy assistance should look like in Michigan. The Company's LMI project responds directly to these recommendations to deliver a solution that reduces duplication of customer efforts while seeking assistance, aligns with State programs, and is grounded in the needs and best practices identified by these collaborative groups.

Q. Beginning at page 14, line 14, of her direct testimony, Staff witness Klocke states "through numerous rounds of audit questions, to ascertain exactly what the LMI Customer Support Enhancement will do or will offer customers and still does not have a clear answer." Has the LMI project implementation produced a more dependable project scope for what it offers customers?

A. Although the LMI Customer Support Enhancement project was in development and early implementation at the time of the Company's initial filing, it has now been operational for four months. In that short time, the project has clearly demonstrated its value in improving access to assistance for all Consumers Energy customers.

The project has already seen a measurable increase in customer engagement and uptake—indicators that the tool is well-designed to meet the needs of the population it is intended to serve. Since its launch on December 12, 2024, over 55,000 customers have interacted with the tool, and 12,000 customers have enrolled in an offering, with 22% of interested customers enrolling in programs (compared to .05% of customers who enroll after being reached via email), ensuring that the efforts put into developing and promoting the tool are yielding tangible benefits. Given its strong foundation, evidence-based design,

immediate positive outcomes, and clear trajectory for ongoing improvement, this LMI project is a reasonable and prudent investment. Funding it now ensures that the Company can continue delivering meaningful support to customers who need it most.

Q. Can the Company provide results that demonstrate effectiveness and progress toward the stated goals of the LMI project?

A. Yes. Since its launch, the LMI project has delivered several measurable outcomes that demonstrate its early effectiveness and validate the Company's approach. Within the first four months of deployment:

- Over 55,000 customers have engaged with the tool since launch, and nearly 30,000 (55%) of those users have self-identified as LMI, indicating high visibility within and interest from the intended user base.
- Of the 55,000 customers who have interacted with the tool roughly 40% completed the full eligibility assessment, successfully identifying one or more programs for which they may qualify.
- Of the 12,000 users completing the flow, nearly 20% have enrolled in more than one offering, demonstrating the effectiveness of the simplified digital enrollment flow in making it easier for customers to access the programs they need.
    - By streamlining the process, customers can quickly and efficiently determine their eligibility and enroll in multiple beneficial programs, leading to better support and improved outcomes for those in need.
- On April 20, 2025, Green Giving was added to the simplified digital enrollment experience. In just the first hour, six customers enrolled—matching the total enrollments agencies achieved in the previous six weeks.
    - Since then, the Company has enrolled 515 low-income customers digitally, while agencies have enrolled 10.

      This contrast highlights the urgent need to streamline enrollment and eliminate administrative barriers. Modernizing the Company's approach is essential to better serve its customers and maximize program impact.

- 87% of users that completed the survey reported that it was extremely easy[2], or easy to complete the experience.

- 56% of users that completed the survey reported that they felt the offerings provided to them were extremely personalized or very personalized to them.

- By implementing the tool, the Company has reduced the need to send approximately 300,000 emails to promote individual products to reach enrollment goals, streamlining the Company's outreach efforts and maximizing efficiency.

- The tool has captured over 3,000 leads for EWR programs[3]. The tool's ability to capture leads organically indicates a user-friendly and effective design, making it easier for customers to navigate and enroll in programs.

These results affirm that the tool is immediately delivering on its intended purpose: reducing enrollment barriers, increasing program visibility, and helping LMI customers more easily access the support they need. Continued monitoring and feedback collection will allow the Company to further refine the tool and expand its impact in the months ahead.

Q. On page 19, lines 5 through 10, Staff witness Klocke states "A main reason Staff does not support this project is because Staff does not believe this project will do anything to fix or prevent the root causes of customers either in or on the brink of crisis. The LMI project will not reduce customers' energy burden, even if they are able to utilize a payment plan, select their due date, or anything else – these solutions are mere band aids to the larger root problem of energy unaffordability." Does the Company agree with this assessment?

[2] Based on a rating scale the rating scale includes:
Extremely Easy
Very Easy
Moderately Easy
Slightly Easy
Not Easy at all

[3] The tool captures leads to send to CLEAR, to then contact customers to schedule Home Energy Analysis appointments.

A. No. While Staff witness Klocke says that the LMI project does not address the root causes of energy unaffordability and merely offers band-aid solutions, it is important to recognize the immediate and tangible benefits this project provides to LMI customers. The LMI project is designed to provide crucial immediate relief and support to those who are currently facing significant energy affordability challenges.

By simplifying enrollment processes, proactively communicating with customers, and integrating and improving existing assistance programs, the project ensures that customers can access the support they need without unnecessary hurdles. This immediate support can help prevent service disconnections, reduce energy burdens, and improve household stability, which are essential outcomes given the current economic realities. This project serves as a necessary step in building a more comprehensive support system for LMI customers. The Company's broader strategy encompasses several key initiatives aimed at addressing both immediate needs and long-term challenges.

Q. On page 15, and page 16, lines 1 through 16, Staff witness Klocke references the LMI project's Simplified Enrollment goal, stating "Staff frankly does not understand why this information regarding enrollment is not already available to customers and is unclear why the Company needs so much money to allow customers to enroll in applicable programs." How does the Company respond?

A. While enrollment information is available on the website and accessible to all customers (and non-customers), it is not presented in a way that is easily navigable or actionable for a specific subset of customers: those in need of assistance. Staff have stated that the tool should be available to all customers, and it is indeed accessible to all customers who are authenticated on the Company's website. Data shows that 8% of customers who have self-

identified within this LMI enrollment flow are market rate customers, falling outside of the LMI eligibility parameters. This demonstrates that these customers are still able to access the flow and enroll in offerings for which they are eligible. The flow does not limit access; it streamlines enrollment, making it easier for customers to understand what programs they are eligible for based on their customer profile.

Staff witness Klocke points out that links to assistance programs exist on the Company's website on page 19, lines 13–14, but that information shared via a static website versus interactive web tool significantly limits its effectiveness and often adds to the burden of figuring out what to do with that information.

For example, recommendations from State collaborative workgroups supported by primary customer research, including surveys and usability testing, show that the current assistance enrollment experience is burdensome, fragmented, and often overwhelming. Research findings include:

- "It takes about 30 minutes, filling out nine forms to begin to sign up for State benefits, assuming steady internet access, device compatibility, and printing/scanning ability"[4];
- "25% of LMI customers indicated say they are not interested in learning about EE (Energy Efficiency) programs because they do not have time to participate[5]"; and
- 51% of LMI customers agree with the statement "I never seem to have enough time to get things done[6]."

Making information available on the website does nothing to address the root cause of some of these difficulties.

[4] From a Consumers Energy customer interview
[5] From third party research conducted by Bellomy
[6] From third party research conducted by Bellomy

The project's simplified enrollment goal is not to duplicate content—it is to deliver a centralized, web and mobile-friendly tool that provides step-by-step guidance based on a customer's individual circumstances. It matches customers only with programs for which they are eligible, explains what is required for enrollment, and allows them to share their information once, rather than repeatedly. The Company has supported and acted on simplifying assistance enrollment in direct response to the complexity of government bill assistance approval flows. With various levels of assistance, programming options, and requirements/eligibility, customers can find themselves lost in the details. Within the LMI project, the focus is on individual opportunity and not a one-size-fits-all information download. This level of customization, guided by real customer insights, goes far beyond a standard web feature or program list. The tool ensures that customers are not just informed—but effectively guided—through the enrollment process with clarity and ease.

The LMI project goes beyond making information available to customers. The funding request reflects the work required to design, build, test, and deploy a digital tool with a personalized, human-centered interface that addresses complex processes and long-standing barriers for LMI customers. Therefore, while the Company agrees that the information should be accessible on the website, the development and deployment of this tool is a distinct, necessary investment that fills a critical gap in the Company's current service model that goes beyond simply making the information available. It is a reasonable and prudent initiative that directly supports equity and ease of access for the customers who need it most.

Q. On page 16, beginning at line 21 through page 17, line 4, Staff witness Klocke stresses that assistance information should be accessible to all customers, and in doing so states (page 17, lines 2 through 6) that "Staff is not convinced that the Company's definition of customers in crisis adequately captures all those customers who could end up in crisis..." How does the Company respond?

A. As noted by Ms. Klocke on page 16, lines 17 through 19, "In an uncertain economic climate, virtually anyone could be in crisis with the loss of a job, unexpected bill, medical emergency, etc." Under the LMI project, the Company has identified low-income customers as "being in crisis" –and moderate-income customers as "one crisis away" from being in crisis. Examples of "one crisis away" include situations such as a missed paycheck or job loss. The scope of the LMI Customer Support Enhancement Project includes exploring ways to support customers who do not currently qualify for low-income assistance but still face significant financial challenges including emergency or unexpected challenges as noted by Staff witness Klocke. In alignment with Ms. Klocke's comments, the intent of this project is to expand support for customers beyond the traditional low-income definition to also include moderate income customers at risk of financial hardship and all customers that may be seeking opportunities to lower their energy bills.

Q. On page 16, lines 6-12, Staff witness Klocke states another core function of the LMI project--Proactive Communications and Program Awareness is unneeded because the Company already conducts outreach. Does the Company agree?

A. No. On page 16, lines 11 through 12, Staff witness Klocke states that the $400,000 cost of this targeted LMI outreach is unnecessary given that "Residential customers, regardless of income, are given outreach via direct mail and email for information about EWR, demand

response, and Renewable Energy Programs." Additionally, Ms. Klocke states on page 17, line 4 "believes all customer classes – not just those identified as low-to-moderate income – should have access to the information the LMI project provides"

The Company disagrees with the notion that targeted outreach is unnecessary. All customers will continue to receive information about available programs and have access to the LMI tool, as discussed above. However, the LMI project's Proactive Communications and Program Awareness initiatives are designed to complement broad marketing efforts by applying focused awareness tactics specifically tailored to the unique needs of LMI customers who face unique and well-documented barriers to engagement.

This is a "yes, and" approach—not an either/or. It ensures the Company continues to engage the full customer base while also delivering more effective, personalized communication to those who are most in need. The foundation of the communications targeted to the LMI customer population is based on identified risk and an assessment thereof based on (1) account and behavior data and (2) information gathered through the self-attestation a customer provides when accessing the larger LMI project flow--that may indicate or serve as evidence that a customer may be struggling now or will be in the near future. This data paired with LMI Mindset Map included as Exhibit A-129 (JRB-4) insights inform proactive communication strategies. There is a planned methodology behind the targeted communications. Consequently, the Company is enabled to anticipate needs, align with customer motivations and preferences, and drive stronger engagement with better outcomes.

Q. On page 17, starting at line 12, Staff witness Klocke discusses another stated goal of the LMI project, New and Improved LMI Offerings, by which the "Staff is perplexed why a new program such as this one would need such expensive 'improvements' already." How does the Company respond?

A. The Company believes it will take a significant, upfront investment to create an infrastructure, both programming and technological, to support the goals of new and responsive LMI offerings, as well as the LMI project as a whole. Part of the infrastructure required is assessing how current programs fit together, what gaps exist between current and potential services, and how to tie everything together for the most efficiency for the overall customer experience.

Q. On page 18, starting at line 9, Staff witness Klocke discusses the final stated goal of the LMI project—Continuous Improvement—where she states, "Again, it appears the cost requests and the overall LMI project itself is too premature to be deemed reasonable and prudent." Why is the proposed LMI project a reasonable and prudent investment for the Company and its customers?

A. This project's goal of Continuous Improvement speaks to the fact that it is not a one-time deployment; it is an evolving solution, especially in this startup phase. The Company is actively monitoring usage patterns and collecting feedback to enhance the tool's performance and expand its capabilities. The lessons being captured today will further strengthen the tool's effectiveness and enable it to reach a broader segment of the customer population over time.

The proposed LMI project is a reasonable and prudent investment because it is directly informed by robust, customer-centered research and is designed to address

well-documented barriers that prevent LMI customers from accessing the assistance they need. The Company initiated primary and secondary research with over 2,000 low-income customers to better understand LMI customers and to identify barriers to awareness about assistance options and participation in utility programs. This research included surveys, interviews, customer panels, and usability tests, and uncovered two primary barriers: a general lack of awareness about available programs and a perception that the enrollment process is overly complex.

In response to these findings, the LMI project is tailored to reduce these specific barriers by improving communication, simplifying enrollment processes, and streamlining customer experience. By doing so, the project aims to improve access to critical assistance programs and ensure more equitable outcomes for vulnerable customer groups. The design of the project is evidence-based, targeted, and aligned with the Company's obligation to serve all customers effectively, particularly those most in need. For these reasons, the investment is both reasonable and prudent, as it addresses a demonstrated customer need with appropriately scoped and strategic solutions.

Q. Please explain why the overall, upfront investment in the LMI project is justified, and how that investment ultimately provides long-term benefits, including utility bill reductions, for customers?

A. The upfront investment in the LMI Customer Support Enhancement Project is both necessary and justified because it lays the foundation for long-term, sustainable benefits that directly improve customer outcomes and reduce energy burdens over time. This investment supports the development, deployment, and refinement of a digital tool that

helps customers more easily identify and enroll in assistance programs for which they are eligible—many of which provide direct utility bill savings.

Historically, LMI customers face multiple barriers to accessing support: limited awareness, confusion about eligibility, and difficulty navigating enrollment processes. By removing these barriers through a streamlined, automated solution, the program increases uptake in bill assistance and energy efficiency offerings—leading to tangible, recurring reductions in monthly utility bills for eligible customers.

For example, customers who successfully enroll in assistance programs may receive monthly credits, arrearage forgiveness, or energy efficiency upgrades that lower usage, which translates to lower bills. By making it easier to access these benefits, the program not only delivers immediate relief but also supports long-term household stability and improved payment behavior, which benefits the broader customer base by reducing uncollectible expenses. Thus, while the initial costs are concentrated at the front end, the return on investment is realized over time. This is an informed, customer-centric investment that aligns with the Company's and goals of affordability, equity, and service quality.

Q. What would be the impact of disallowing the LMI Customer Support Enhancement Project?

A. Disallowing this project would have significant and immediate negative consequences, particularly for the Company's most vulnerable customers. The LMI digital tool was developed to address persistent challenges—such as lack of awareness, confusion about eligibility, and difficulty navigating the application process. These challenges disproportionately affect low-income households, who are often already struggling with

affordability and energy insecurity. A disallowance of this project means effectively deferring meaningful relief and continuing to rely on fragmented systems that are not meeting the needs of these customers. Moreover, this project benefits all ratepayers by promoting broader enrollment in assistance and energy efficiency programs, which in turn can reduce bills, improve payment behavior, and ultimately lower the level of uncollectibles carried by the utility. In sum, this is a proven, customer-informed solution ready for deployment. Disallowing the project unnecessarily extends hardship for low-income customers and undermines the Company's commitment to equitable access and affordability.

Staff Witness Klocke Regarding Click To Chat, Web Chat AI, And Self-Service Mobile App

Q. Staff witness Klocke also recommends historical, bridge, and test year disallowances for several Customer-related IT Enhancement projects. Please discuss.

A. Staff witness Klocke's proposed disallowances include $45,683 in capital for the historic year ended December 31, 2023, as well as $2,958 in capital expenditures for the bridge year period ended December 31, 2024 for Click to Chat (Staff witness Klocke Direct Testimony, page 5, lines 20 through 23, through page 6, lines 1 and 2); proposed disallowances for Web Chat AI include $180,565 in capital expenditures, and $14,929 in O&M for the test year ending October 31, 2026 (Staff witness Klock Direct Testimony, page 8, lines 16 through 18); and finally, proposed disallowances for Enhancements to the Company's Mobile App include a decrease of $61,562 in historical capital, $274,116 in capital costs for the year ended December 31, 2024, $598,472 in capital costs for the year ending December 31, 2025, and $550,025 in capital costs and $6,510 in O&M costs for the

projected test year ending October 31, 2026 (Staff witness Klocke Direct Testimony, page 10, lines 11 through 14).

Q. Does the Company, in general, agree with Staff witness Klocke's reasoning?

A. No. All three digital tools that Staff witness Klocke puts forth for disallowance are: (1) based on industry research that supported customer desire for chat-based applications; (2) currently in existence and in use by customers; and (3) consequently require updating and maintenance. For those projects previously supported in rate cases Staff have not pointed to any circumstances that have emerged since the Commission issued these orders that should cause them to revisit.

The Company has previously cited JD Powers findings regarding chat tools, including one that found that live chat has become the leading digital contact method for online customers with 42% of customers preferring live chat compared to just 23% for email. The development and maintenance of these tools are not driven by utility preference but are a direct response to the expressed needs and expectations of the customers the Company serves. Furthermore, peer institutions have both similar tools and similar restrictions to customer assistance hours (see Help Center | DTE Energy[7] and Contact Us | AEP Energy[8]), setting Consumers Energy on equal footing with its peers, implementing best practices by providing customers with channels of choice.

In providing different channels of communication, it becomes a necessary obligation for the Company to update and maintain the tools customers prefer to use. From the emerging Web Chat AI tool to the Click to Chat tool available to business customers and the established and popular Mobile App, investments into these enhancements ensure

[7] https://www.dteenergy.com/us/en/quicklinks/help-center.html
[8] https://www.aepenergy.com/contact-us/#:~:text=Chat,am%20%E2%80%93%207%3A00%20pm.

these tools work as requested or expected. To that end the associated investment should be considered reasonable and prudent.

Q. Does the Company agree with Staff witness Klocke's reasoning for recommending the disallowances for Click to Chat.

A. No. Starting on page 5, line 20, Staff witness Klocke states Staff's points against the Click to Chat project—including finding "the project does not offer any new technology or features that are innovative, nor does it represent any cost savings" (page 6, lines 7 to 8).

She further restates on page 7 lines 6 through 12 that "Staff also has concerns that just 314 uses of Click to Chat have been reported by the Company's agents. (Staff Exhibit S-11.1.) For a project that has now been available for over three years, usage is very low. In that same audit response, the Company stated that it currently has 'no tracking regarding how many of their [customers'] problems/issues were fully resolved using this feature.' (Staff Exhibit S-11.1.) Staff finds it troubling that the Company is not tracking the results of this project in an effort to measure its success."

The goal of Click to Chat was not to only reduce call center costs, but to offer customers another channel through which to reach the Company and potentially self-serve.

Additionally, Staff continues to support only the implementation of IT applications that are considered valuable because of associated cost savings. This fails to consider that both customer preference and accessibility have value of their own. On page 7, lines 13 to 14, Staff witness Klocke states that "any major problems will still require CSR intervention" but fails to recognize: (1) Click to Chat was never envisioned or intended to solve urgent customer inquiries, and (2) that both time and costs savings might be realized

in the disposition of common or simple issues that customers may solve via chat without any involvement from the Customer Service personnel.

The administrative law judge ("ALJ"), and ultimately the Commission, recommended recovery of historical costs for Click to Chat in Case No. U-21585 (See MPSC Case NO. U-21585, March 21, 2025 Order, page 185 "The ALJ agreed with Consumers that, although the Click to Chat function does not save money, it contributes to the provision of utility service").

Q. Does the Company agree Staff witness Klocke that usage of the Click to Chat tool is low?

A. No. On page 7, line 6, Staff witness Klocke cites the number of completed Click to Chat interactions as 314 and then states that "For a project that has now been available for over three years, usage is very low." However, the Click to Chat project implementation had been delayed until late October 2023. Consequently, the project has been available for approximately 18 months, not three years, effectively doubling the usage statistics. When added to the fact that Click to Chat was initially available as a non-market soft launch to business customers, Staff witness Klocke has understated the number of customer interactions with the tool and underestimated the potential of a relatively new channel.

Q. Does the Company agree with Staff witness Klocke's reasoning for recommending the disallowances for Web Chat AI Enhancements. Please discuss.

A. No. Staff witness Klocke states on page 9, line 5that Staff finds Web Chat AI "redundant and not worth the cost." And "In essence, the Web Chat will simply be aggregating information that is already available to customers on the Company's website." (page 9, lines 11-12). The Company maintains that chat functionality is a customer channel of

choice, and as such should be supported, maintained, and updated as necessary. Additionally, Web Chat AI is in the early stages of enhancement and consequently cost savings are unquantified at this time. The Company remains committed to the tool as an alternative channel of interaction with the Company. Not every customer has an issue or question that rises to the level of calling a service center and the Web Chat AI tool will provide relevant information in an instant and the customer may interact according to their situation.

Q. Please discuss Staff witness Klocke's reasoning for recommending the disallowances for Mobile App Enhancements.

A. Starting at page 11, line 6, Ms. Klocke states that Staff is against the Company's Mobile Application funding—and in this case that includes the funding for enhancements—recommending a decrease of $61,562 in historical capital costs for the year ended December 31, 2023, $274,116 in capital costs for the year ended December 31, 2024, $598,472 in capital costs for the year ending December 31, 2025, and $550,025 in capital costs and $6,510 in O&M costs for the projected test year ending October 31, 2026 (page 11 , lines 11 through 14).

She states on page 11, lines 21 through 23, and page 12, lines 1 through 4 that "Staff's position regarding the Mobile App has remained the same in every case it has been presented in, starting with Case Nos. U-20697, U-20963, U-21224, U 21389, electric cases, and Case Nos. U-21148, U-21308, and U-21490, gas cases. In each of those cases, Staff's position is that the Mobile App represents functionality that is duplicative of the Company's website and is therefore unnecessary and its over $10 million total costs should

not be passed on to ratepayers." Further, page 12, lines 7 and 8, "the Company has never conclusively proven a need for such an application or customers' interest in it."

Q. Does the Company agree with this assessment?

A. No. The Company has consistently supported the development and launch of its Mobile Application for several reasons, including those outlined below. It is for these reasons that the Mobile App enhancement dollars should be allowed.

1. The Commission took no position on the Mobile App in Case No. U-21224, which was settled. However, the Commission expressly approved the Mobile App project on its merits in Case No. U-21389 finding "The Commission agrees with the company's arguments that, while there may be some redundancy in the functions of the app and the website, there is value in offering varying communication channels to meet customer needs. As pointed out by Consumers in its exceptions, it could be argued that there is redundancy between the functions of call centers and the company's website as both are avenues to receive customer payment. As technologies and customer preferences evolve, the Commission finds that duly supported, reasonable, and prudent expenditures to meet those preferences are appropriate for recovery."(MPSC Case No U-21389, March 1, 2024 Order, page 83.);

2. Since the app's launch, there have been almost 1.5 million downloads and the Company has seen the popularity of the app continually increase, with a current share of digital traffic at over 28%, and now exceeding Desktop Web use (App use of 5.3 million sessions vs Desktop use of 4.6 million sessions for 2025 YTD);

3. The Mobile App is not a carbon copy of website functionality, nor was it conceived in this way. As the Company has stated several times, the Mobile App has separate functionality and has the added benefit of not needing a web interface to interact with the Company. The Mobile App was developed to provide a streamlined experience for customers, allowing them to complete common interactions quickly and efficiently on their phones, with features like simple login and direct access.

4. The Mobile App continues to serve as a reliable platform during potential website downtimes, ensuring that customers can still complete routine transactions like bill payments.

5. As shown by adoption and use statistics above, customers prefer to perform more complex interactions in the mobile app and additional functionality should be expanded in response.

These points highlight the recognized functionality and growing popularity of the Mobile App amongst Consumers Energy's customers for an array of their interaction needs. The related enhancement dollars should be allowed to support and enrich the Mobile App experience.

Website Redesign

Q. Staff witness Klocke often mentions disallowances in conjunction with a desire to see the Company's website update realized saying regarding Web Chat AI on page 9, Lines 12-15 "Staff has and does support the Company's planned website redesign and feels it would be a much better use of Company resources – and ratepayer money – to update the website to make any general, frequently asked questions easily found."). and includes this language in relation to the LMI project, the Mobile App, and Enhancements to Company chat functionality. Please respond to the suggestion that the website is the central technology vehicle for the Company.

A. The Company agrees with Staff witness Klocke that a current and robust website is beneficial to an organization that provides a large volume and wide variety of information and resources to their customer base. The Company has requested and received support for its website redesign (Case No. U-21308, Case No. U-21224, and Case No. U-21490) and has been delayed in fully realizing its stated plans (please see Company witness Stacy H. Baker's rebuttal testimony for information on overall website redesign progress). However, in relation to the Mobile App and chat functions, the Company has stated and reiterates here that these tools are not intended to have all the functionality of the website, nor are they intended to replace the website or other customer channels. The customer IT projects

referenced by Staff witness Klocke provide support for specific yet complex interactions that are not necessary in all channels of communication.

The Company remains committed to updating its website to provide accurate and up-to-date information for all of its customers. As the Company works through the IT solutions in progress to achieve this goal, it also remains committed to growing channels utilized by customers.

Attorney General O&M Disallowance for DCO and Analytics and Outreach

Q. Does the Company agree with Attorney General witness Coppola's recommendation, starting at page 174, line 12, to page 175, line 15, to disallow $2,325,000 from Analytics and Outreach related O&M.

A. No. The Company disagrees with Attorney General witness Coppola's recommendation to disallow $2,325,000 in Analytics and Outreach related O&M. While Attorney General witness Coppola notes (page 174, lines 19 to 20) that the Company responded to a discovery request including historical and forecasted staffing, work activities, and associated outcomes he then dismisses the information provided to be of insufficient clarity.

Starting at line 3 on page 175, Attorney General witness Coppola shares the Company's personnel numbers, but continues to state that when it came to accurate responses regarding customer interactions, "From the response, it is not clear what customer interactions entail, why there are so few, and why they decline from 2022 and stay the same between 2024 and the projected test year when the number of employees and contractors in this function increases." The Company provided overviews of the Analytics

and Outreach department's responsibilities and activities as seen in Exhibit AG-60, page 1, as well as work units, headcounts, and budgets.

The Analytics and Outreach group serves a vital function for incorporating customer feedback and data into the Company's operations, which directly contributes to improving customer experience. This allows the company to use its resources more efficiently, target communications to precise customer segments, and select programs that are most likely to provide customer value.

Program priorities include:

- All MPSC reporting – providing reporting metrics and data as required or requested by internal stakeholders
- Estimated Time of Restoration ("ETR" – utilizing Machine Learning in real time, to provide an ETR when a customer loses power, on blue sky days through catastrophic storms)
- Customer Experience Index – supporting the Company's top level goal of consolidation of all live and automated phone calls, app and web traffic, and customer experience surveys across all channels
- Data Automation – centralizing all data outputs from the dozens of source systems and properly storing and maintaining in a centralized resource
- Data Quality – ensuring accurate Customer information for address, email, phone numbers, etc. - improving communication accuracy
- Data Visualization – the execution of all metrics tracked by both Customer Operations and Customer Experience
- Problem Solving – deep dive analysis into the most granular data to support the improvement of customer impacting metrics

Q. Does the Company agree with Attorney General witness Coppola's recommendation to disallow $536,000 or half of the original $1,072,000 request from O&M related to DCO.

A. No. Starting on page 176, lines 5 through 17, Mr. Coppola argues there is a lack of information about who and what comprise the DCO organization.

Mr. Coppola states "it is not clear why most of the system functions already developed would require repeat work using the same number of employees and contractors every year. The general description of accomplishments does not make a compelling case that significant value is being generated. There is insufficient support to justify the number of resources assigned to this function. The evidence is inadequate, and the expense level remains unsupported." See Direct testimony of Mr. Coppola at page 176, line 19, through page 177, lines 1 through 5.

The DCO manages a channel that gets more than 45 million customer interactions annually and provides customers with a valuable self-service tool when managing their energy consumption. The teams' services are particularly valuable when viewing 2024 statistics for the Company's website and mobile application, including 15.7 million views related to checking billing status, 13.8 million related to payments via web or app, and 4.5 million views to view outage status. The DCO team keeps the website and mobile app running, accessible for and responsive to Consumers Energy customers as a well-used channel of choice. The DCO team is critical to the success of the company's objective to digitize more transactions to better serve customers on the website, which is a more cost-effective means of serving customers than other channels.

Additionally, as evidenced in Exhibit AG-60, page 2, overall costs for DCO O&M have been relatively decreasing as the group finds efficiencies and constancy in the technologies it supports.

Attorney General on Affordability

Q. On pages 16 and 17, lines 4 through 9 and 2 through 10, respectively, of his direct testimony, witness Coppola states that capital spending will pose a significant burden on residential customers and business bills. What options does the Company have available to assist customers?

A. Company witness Neal P. Dreisig's rebuttal testimony discusses the economic effect of capital spending on both residential and business bills, including the Company's efforts to balance the cost of reliability and safety with rates. In his testimony, witness Dreisig references both the Company's energy-efficiency programs and its LMI assistance Consumers Affordable Resource of Energy ("CARE") Program as examples of the Company's commitment to providing customers with energy assistance.

Q. Please provide details about how the Company's energy efficiency and CARE program provide assistance to ratepayers.

A. The Company's CARE program is designed to assist income-qualified customers in managing their energy use and bills more effectively. CARE provides customers with bill assistance via a 24-month program that includes a fixed monthly bill—offering a consistent, reduced monthly payment plan that makes budgeting for energy expenses more manageable. As customers make regular, on-time payments, existing past due balance will be forgiven. Customers may also be provided with no-cost, in-home energy efficiency upgrades to help reduce energy costs

Q. Does Consumers Energy offer other assistance programs for qualifying customers?

A. Yes. Consumers Energy offers assistance via several additional programs, including State and Local programs. Details may be found at Payment Plans & Assistance | Consumers Energy.[9] Additionally, investment in the LMI project will allow the Company to better assist customers enroll in programs.

CUB Witness Bunch's Affordability and Uncollectable Discussion

Q. Starting on page 4 of his testimony, CUB witness Bunch also voices concern about the Company's proposed rate increase, citing its effect on affordability for low-income and senior customers. Starting on page 7, lines 3 through 4, CUB witness Bunch provides the source for calculations that follow. What is that source?

A. Mr. Bunch is referencing data from the Company's quarterly reports filed in the docket for Case No. U-18120 the Rule 51 report), a snapshot of which is in Figure 1 below.

Figure 1

Rule 51 Trending	Jan-22	Feb-22	Mar-22	Apr-22	May-22	Jun-22	Jul-22	Aug-22	Sep-22	Oct-22	Nov-22

Q. Does the Company dispute CUB witness Bunch's findings using this data?

A. Yes.

[9] https://www.consumersenergy.com/residential/account-and-billing/billing-and-payment/payment-assistance

Q. Please explain.

A. For example, on page 7, lines 4 through 5, CUB witness Bunch uses this data to support his assertion that delinquent accounts are growing significantly.

Q. Is this an accurate statement?

A. CUB witness Bunch is correct when he states, "The number of accounts that are 90+ days in arrears has been growing" (when referring to years 2022-2024). However, the significance of this growth is open to interpretation due to the potential exaggeration from the chart's scaling. For example, if the same dataset referenced on page 7, lines 3 and 4, can be expanded to show the period of 2020-2024, customer accounts in arrears did increase (Figure 2), but also saw several decreases. Additionally, over the same 2020-2024 timeframe, correlated dollar amounts arrearage decreased (Figure 3).

Q. Why does this matter?

A. By selecting a specific timeframe on which to focus, CUB witness Bunch provides only the context of the data and no social, political, or economic context for which there might logically be a drop or a surge in arrears. He also fails to offer policy implications, either macro or micro (e.g. the way arrears were reported or accounted for), context.

Figure 2

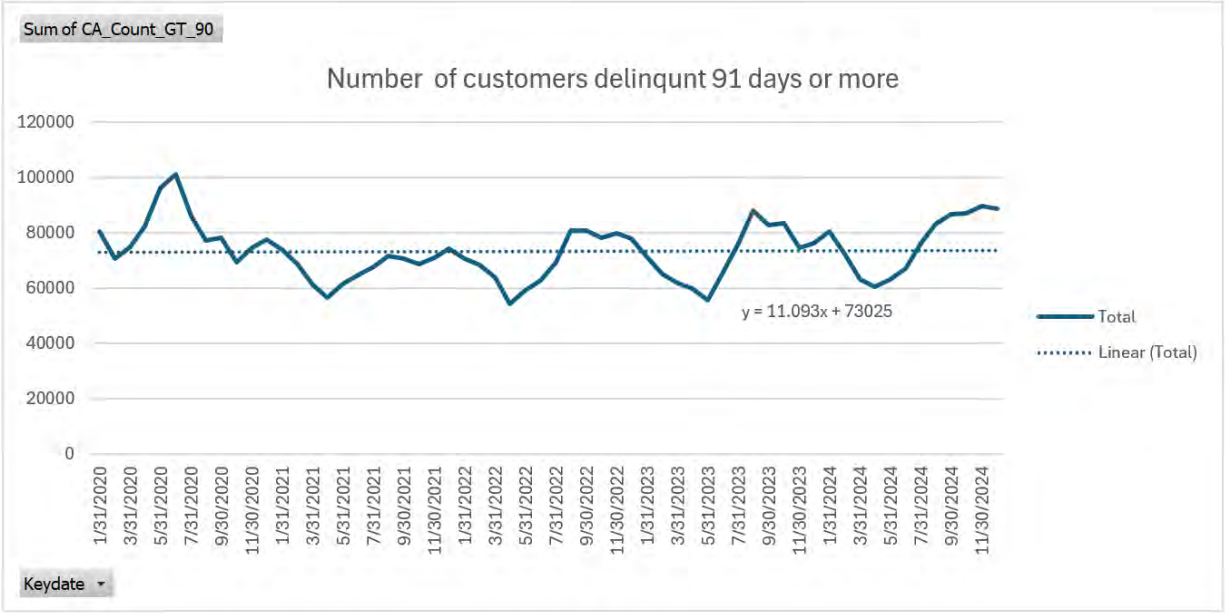

Figure 3

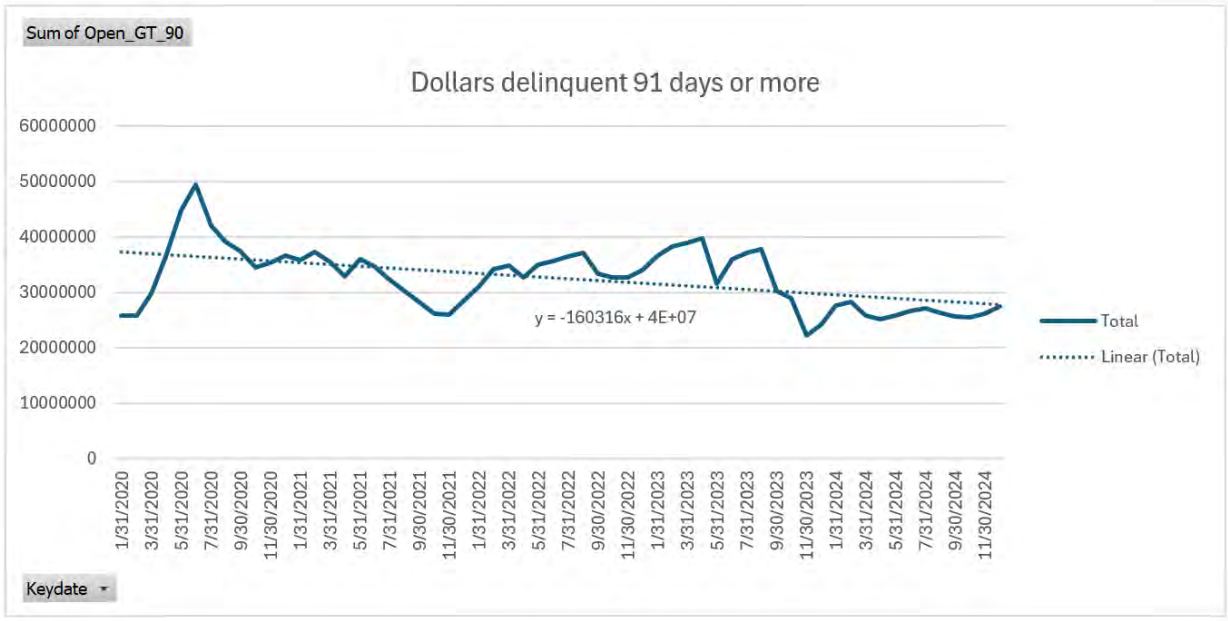

Q. On page 7, lines 9 through 10, CUB witness Bunch indicates "Long-term delinquencies have grown by about 25% over the past three years." Is this accurate?

A. Mr. Bunch may be referring to the percent change in customer count in the Over 90 bucket, from Jan 2022 to Dec 2024: (88,577 – 70,694) / 70,694 = +25%. in Figure 1. Though this is the accurate percent change in customer count, a comparison of a data point from one month (January) to the data point from a different month (December), may not be comparable since arrears is cyclical. Also, it's worth noting that while customer count did trend up, dollars in the 91+ days-past-due bucket trended down over the time period highlighted by CUB witness Bunch.

Q. On page 8, line 5, Mr. Bunch states "From 2021 to 2023, residential uncollectible expenses increased 53.7%." Is this accurate?

A. The date on page 8, line 6, and on which CUB witness Bunch bases his statement is accurate and was cited from Company-provided data.

Q. Starting on page 8, line 10, and continuing through page 10, line 6, CUB witness Bunch discusses the Company's rate impact in conjunction with inflation and spend. Does the Company agree with his testimony?

A. Company witness Dreisig discusses the Company's position on spending and rates and the rate of inflation in his rebuttal testimony.

Q. On page 10, starting at line 7 and continuing through page 8, after noting the assistance levels the Company provides, CUB witness Bunch concludes "I find that Consumers' customers received almost $24 million (or 57%) more in various forms of assistance in 2023 than in 2022. Yet the number of customers who are more than three months behind, and the dollar value of residential uncollectibles, are both surging." How does the Company respond?

A. The Company recognizes that many of its customers either cannot pay or cannot pay the totality of an energy bill. As previously noted, Company witness Dreisig discusses the efforts the Company has taken to keep rates in line with inflation and the Company's efforts to balance the cost of reliability and safety with rates. In addition to these efforts, the Company has provided increased assistance available to numerous customers but there are other factors that may contribute to arrears or uncollectables. CUB witness Bunch's statements provide one factor but the issues are multi-factored.

Q. CUB witness Bunch questions (page 11, lines 9 and 10) why increased assistance has not affected and not offset the observed increase in delinquent accounts and uncollectibles and reasons that it is because the Company is not reaching, or reaching only a subset, of those who are in most need. How does the Company respond?

A. The Company is actively trying to reach both those who are currently delinquent or in arrears and those who might be approaching that status through the LMI Customer Support Enhancement Project.

MEC Witness Napolean Regarding the EWR Programs

Q. MEC witness Napolean states (page 18, lines 6-11) that the Company's EWR program savings and design are relevant in the present case, since they inform Consumers Energy's investment plan. Further, she states that the focus of the gas efficiency program should be on electrification measures as well as weatherization and building envelope measures. Does the Company agree?

A. No. Please reference Company witness Neal P. Dreisig's rebuttal testimony for a discussion on gas efficiency as related to electrification and declining gas consumption. The Company's next EWR plan (MPSC Case No. U-21680) will be filed in August 2025 and its reconciliation MPSC Case No. U-21671 Is currently pending before the Commission and by statute, these programs are designed and reconciled outside of general rate proceedings, and the proper venue to make suggestions on EWR program design would be in a reconciliation or plan filing.

CUB Witness Denzler's Disallowance of COST Projected O&M Savings

Q. Starting on page 27, line 3, of his testimony, CUB witness Denzler supports the COST project, including supporting the project's objective of tracking customer orders in real time and saving costs associated with incoming calls for information and outgoing truck rolls based on erroneous or out-of-date information. However, he recommends the Company's projected O&M savings be disallowed in the present case, and as a counter to the Company's discovery response that these savings are estimated and not included in present Company projects. Mr. Denzler states that all projected costs are estimated and therefore able to be reduced accordingly. How does the Company respond?

A. The Company agrees the COST project will result in significant savings, but it is important to note that the project is in the early stages, and that the savings are in fact estimated as part of the related cost/benefit analysis, and subsequently have not been accounted for in Operations other than IT implementation, and consequently should not be pulled from the present case.

The Company's test year forecast for the COST project should be approved, excluding O&M savings that cannot be realized within the test year. During this period, the Company will complete the project, without yet benefiting from the anticipated savings. It is unreasonable for CUB witness Denzler to assume immediate realization of savings upon project completion. Approval of the project's spending should be based on the understanding that O&M savings will be evident in the Company's subsequent rate case.

While Mr. Denzler's focus is on the financial aspects, the benefits of the project extend beyond mere cost savings. The project aims to enhance customer interaction and streamline Company processes, which are not fully captured in a traditional cost/benefit analysis. The reduction in contact center calls and improved scheduling efficiency are expected to lead to better resource utilization and customer satisfaction.

Q. Does this conclude your rebuttal testimony?

A. Yes.

REBUTTAL TESTIMONY

OF

AMY M. CONRAD

ON BEHALF OF

CONSUMERS ENERGY COMPANY

May 2025

Q. Please state your name and business address.

A. My name is Amy M. Conrad, and my business address is One Energy Plaza, Jackson, Michigan 49201.

Q. Are you the same Amy M. Conrad who previously submitted testimony in this case?

A. Yes.

Q. What is the purpose of your rebuttal testimony?

A. The purpose of my testimony is to rebut the direct testimony and exhibits presented by witnesses for the Attorney General and the Michigan Public Service Commission ("MPSC" or the "Commission") Staff ("Staff") regarding Consumers Energy Company's ("Consumers Energy" or the "Company") incentive compensation plan and the recommendations to exclude incentive compensation costs from the revenue requirement in this case. For the reasons discussed in my direct testimony and in this rebuttal testimony, the Commission should find that the incentive compensation costs linked to operational measures that Consumers Energy is seeking to recover in this case are a reasonable cost of doing business and should be included in rates. Consumers Energy has acted reasonably in paying its employees at market levels. It would be unreasonable not to allow the Company to have that reasonable and appropriate business expense recovered in rates.

Q. How is your rebuttal testimony organized?

A. In Section I of my rebuttal testimony, I address the direct testimony and exhibits presented by Attorney General witness Sebastian Coppola. In Section II, I address the direct testimony and exhibits presented by Staff witness Theresa McMillan-Sepkoski.

Q. Are you sponsoring any exhibits with your rebuttal testimony?

A. Yes. I'm sponsoring Exhibit A-132 (AMC-4), which shows the data that was attached to audit response U21806-SA-CE-028, but which was excluded from Staff witness McMillan-Sepkoski's Exhibit S-8.2 reproducing that response.

Q. Were these exhibits prepared by you or under your supervision?

A. Yes.

I. REBUTTAL TO ATTORNEY GENERAL WITNESS COPPOLA

Q. At page 187, lines 12 through 13, of his direct testimony, Mr. Coppola states: "Generally, the Company's short-term incentive plans are too heavily weighted toward financial measures that mostly benefit shareholders and not customers." Do you agree?

A. No, the Company is not requesting recovery of any Employee Incentive Compensation Plan ("EICP") dollars in this case related to the financial metrics**.** The Company in this case is seeking recovery only for the incentive costs at target level associated with the operational goals portion of the short-term incentive (EICP) for both non-officers and all officers. Consumers Energy has adopted incentives that are designed to emphasize operational performance criteria in areas that are critical to the Company's utility business and customers. Focusing employees on these goals provides both qualitative and quantitative benefits for Consumers Energy's utility customers.

Q. At page 188, lines 10 through 13, Mr. Coppola states: "Even mediocre performance will be rewarded if only a single metric is achieved. This is a very generous incentive plan that is not directly connected with achieving superior customer benefits before making threshold incentive payouts." Do you agree?

A. No. Employees, as a whole, must re-earn the incentive/at-risk portion of compensation each year. Moving to a banded goals payouts for each operational measure sets minimum (thresholds), targets, and maximum payout. The Company is only seeking recovery of target level payout. It is common market practice to use individual goals that set minimums (thresholds), targets, and maximum goals (banded goals) with payout percentages based on level of achievement. Structuring the payout to consider performance of each goal individually also ensures that employees have an independent motivation to achieve each goal regardless of whether another goal may be off target to meet payout levels during the year. This removes any potential mis-incentive to "give up" on one goal just because another may have become unlikely to be achieved. Each goal has the ability to earn an EICP payout on its own achievement, so every goal remains important and employee motivation to attain each goal individually remains high.

Rewarding employees for the level of achievement aligns pay for performance. Employees know what the minimum level of achievement is to receive a payout and have visibility to what above-target rewards they can receive for over achievement. This structure motivates employees to attain the target or goal but still allows for recognition for some below-target performance and additional reward for above-target performance.

If the threshold to achieve a payout was set at a level viewed as unachievable, it would be difficult to maintain employee motivation and would result in less customer

benefits. Overall compensation levels including the EICP are established at a target (100%) level that is not excessive. The incentive compensation portion of the Company's total compensation ensures that employees are provided a reasonable incentive to achieve exceptional performance levels. The Company's proposal to include incentive compensation costs at target levels will result in the Company absorbing the incentive compensation costs in those years when the actual payouts are greater than target level. Thus, shareholders will absorb any resulting increase in costs arising from above-target performance.

Q. At page 188, lines 13 through 14, of his direct testimony, Mr. Coppola states: "[T]he fact that the performance measures use CMS Energy financial information and comingle electric and gas business measures is a concern." Do you agree?

A. No. The incentive structure incorporates continuous improvement, safety, quality, cost, delivery, morale, and financial performance measures. Performance in these areas is critical for the Company's success in its electric public utility business. For purposes of efficiency and improved service, the Company has combined operations as one organization. For that reason, the plan contains both gas and electric measures. The related incentive expense is then allocated between electric and gas businesses based on multiple factors determined by the Accounting Department based on the type of activities the departments or business units perform. These factors include but are not limited to: (i) percentage of time; (ii) property, plant, and investments; (iii) operating revenue; (iv) headcount; and (v) labor. Only the gas portion of the EICP expense is being requested in this case. The Company has used this same approach for many rate cases with Commission approval of the recovery of the costs associated with the operational goals.

Q. At page 188, of his direct testimony, Mr. Coppola states: "the Company has stated that it continues to pay salary increases each year of approximately 3.5%." Do you agree?

A. No. For rate making purpose, the Company follows the direction of the Commission's Order in Case No. U-20963 and uses the same inflation factor to adjust both labor and non-labor expenses for determining projected labor costs. Consumers Energy's compensation is designed to be competitive with what is seen in the labor market including rewarding and motivating talent rather than trying to keep up with inflation.

Q. At pages 186 through 187 of his direct testimony, Mr. Coppola discusses various reasons that he disagrees with the Company's request to recover incentive compensation costs in rates. Do the concerns and issues he has identified in his direct testimony provide a valid basis to not allow any recovery of incentive compensation costs in rates?

A. No. I disagree with his analysis and his conclusions. Mr. Coppola's conclusion that Consumers Energy's incentive compensation plans do not benefit customers is not correct. A wide body of research supports the view that, when properly selected and implemented, as has been done with the Consumers Energy plans, incentives motivate employees, focus employees on a company's goals, and increase both individual work performance and team performance. The overall compensation levels are reasonable. The incentive compensation is part of the overall reasonable compensation level, not an addition to it.

Q. At pages 186 through 187 of his direct testimony, Mr. Coppola states that "the average achievement rate for the past five years was 66%". Do you agree?

A. No. I disagree with his analysis and his conclusions. The EICP operational payouts averaged 105% as shown in the table below:

Performance Year	Operational Goal Payout %
2020	125%
2021	75%
2022	109%
2023	94%
2024	124%
5 Year Average	105%

The Company is requesting recovery of target level payout for operational measures only. When setting payout levels, threshold is set at a level of achievement that can typically be reached 80% to 90% of the time in a 10-year period. Maximum payout is for exceptional performance (10% to 20% of the time in a ten-year period). These levels are to engage the employees in meeting the goals. Employees must re-earn the incentive at-risk portion of compensation each year. If the threshold to achieve a payout were set at a level viewed as not achievable, it would be difficult to maintain employee motivation and would result in fewer customer benefits. When goals are challenging yet achievable, employees are motivated to increase productivity and performance to achieve the goal.

II. REBUTTAL TO STAFF WITNESS MCMILLAN-SEPKOSKI

Q. What is the pay process for officer incentive targets?

A. As stated on page 21 of my direct testimony, Consumers Energy creates a compensation package for officers that delivers base salary, annual incentives, and long-term incentives (excluded from the Company's request in this rate case) targeted at the 50th percentile of the market, as defined by a Compensation Peer Group approved by the Compensation

Committees of the Board of Directors. Annually, the Compensation Committees engage an independent third-party consultant to provide advice and information regarding compensation practices of a Compensation Peer Group.

Q. Is survey data information for the third-party consultant proprietary information?

A. Yes. Consumers Energy's Compensation Committees engage an independent third-party consultant to provide information regarding officer compensation practices of the Compensation Peer Group as well as additional information from Willis Towers Watson published surveys of compensation in the public utility sector and general industry.

The Willis Towers Watson survey sources used by Pay Governance are produced solely for use by database participants and are maintained by Willis Towers Watson in connection with the participant's own internal human resources management department. The surveys are the confidential and proprietary work product of Willis Towers Watson, which owns all related intellectual property rights. Pay Governance has written consent from both Willis Towers Watson and CMS Energy to use the surveys on CMS Energy's behalf. Pay Governance is prohibited from using or reproducing the database and survey reports prepared by Willis Towers Watson.

Q. Is the proprietary nature of officer compensation the reason the Company did not provide Staff with the compensation level of the top five officers compared to market median referenced in Staff Exhibit S-8.2?

A. Yes. As illustrated in the Company's response shown in Staff Exhibit S-8.2, the market median information requested is confidential, proprietary, and commercially sensitive data belonging to third parties. Consumers Energy is contractually prohibited from sharing this information.

Although the Company is prohibited from sharing the market data used in setting compensation for its top five officers, the Company recognizes that it could be helpful for Staff to have access to some market data to evaluate the reasonableness of the compensation included in rates for the Company's top five officers. Therefore, the Company compiled and provided non-confidential market data using the following compensation elements from the Compensation Peer Group's publicly filed proxy statements: salary, stock awards, and non-equity incentive.

Because this market data uses only publicly available non-proprietary information, it does not perfectly represent the information that the Company used to benchmark and assist the Compensation Committee to determine compensation for Consumers Energy's top five officers. But, that does not support the conclusion that it is inadequate to support the level of compensation for the Company's top give officers. First, the proprietary benchmarking information alone does not mechanically decide how compensation will be set. When making pay adjustments, the Compensation Committee considers the CEO's recommendations, along with proprietary Compensation Peer Group data, internal equity, tenure, and other proprietary market data from surveys provided by the independent compensation consultant. Actual compensation decisions are based on the following as described on page 21 through page 24 in my testimony. Second, the data provided in Exhibit A-132 (AMC-4) is sufficiently consistent with the proprietary data that it does allow Staff to see a valid comparison of the compensation of the highest paid through the 2nd, 3rd, 4th and 5th highest paid named officers compared to the Company's compensation peer group. As Staff indicated, it was able to review the proprietary Pay Governance report under the following conditions set forth by the proprietary owners, Pay Governance:

> That it will review these materials in the presence of an appropriate representative of CMS and shall keep these extracts strictly confidential and shall not copy or distribute these extracts to any other party, shall use them solely for the purpose of this inquiry and shall exempt Pay Governance from public disclosure under any other inquiry or applicable freedom of information or open records acts.

As the owner of the reports, these were the conditions Pay Governance required. These were not limitations imposed by Consumers Energy. The report that Staff viewed contained the same data shared with the Compensation Committee of the Board for their decision making on officer compensation. In other words, Staff saw the exact data used in making the compensation decision for the top five officers.

Q. At page 8 of her direct testimony, Ms. McMillan-Sepkoski states that, "There was no financial presentation of the compensation data that Staff needed to examine to make a valid comparison?" Do you agree?

A. No. The presentation contained individual charts for all the officers that report to the Chief Executive Officer with the officer names redacted. These charts contain the percentages of base salary, total cash compensation and total direct compensation compared to market. The market data position titles were also contained on the charts. These charts allowed for a visual comparison of the position relative to the market of the top officers. There was also a summary table that illustrated the three market data references (Peer, Investor-Owned Utility, and General Industry) with "x" marking the position compared to the market each officer fell into (i.e. Below 15% of the market range, within +/- 15% of market, or Above 15% of the market range) for all officer positions. The information that Staff claims was missing was there.

Q. Do you agree with Staff's recommendation to exclude the top five officer operational goal annual incentive expense?

A. No. As stated above, having the officers hold specific operational measures provides a stronger linkage to Company operational incentive priorities that support customer benefits. This is a result of the addition of 30% of officer pay directly linked to operational measures. Starting in 2022, the officer operational goal modifier was removed, and the operating cash flow measure was replaced with the same operational measures as non-officers with a weighting of 30%.

In previous cases, the Company regarded the work performed by the top five officers as focused broadly across the entire CMS Energy enterprise; however, in light of the move to a 30% weighting on Consumers Energy-specific operational measures for EICP, we now have a measurable component of their compensation linked directly to work on behalf of the utility and to operational outcomes that benefit customers. Under the Company's current proposal in this case, shareholders continue to bear 100% of the cost of incentive compensation for financial measures and above-target operational measure performance.

Q. Does this conclude your rebuttal testimony?

A. Yes.

STATE OF MICHIGAN

BEFORE THE MICHIGAN PUBLIC SERVICE COMMISSION

In the matter of the application of **CONSUMERS ENERGY COMPANY** for authority to increase its rates for the distribution of natural gas and for other relief.	)))))	Case No. U-21806

REBUTTAL TESTIMONY

OF

NEAL P. DREISIG

ON BEHALF OF

CONSUMERS ENERGY COMPANY

May 2025

Q. Please state your name and business address.

A. My name is Neal P. Dreisig, and my business address is 1945 West Parnall Road, Jackson, Michigan 49201.

Q. Are you the same Neal P. Dreisig who previously submitted testimony in this case?

A. Yes.

Q. What is the purpose of your rebuttal testimony?

A. The purpose of my testimony is to rebut testimony associated with concerns on the Natural Gas Delivery Plan ("NGDP") by Attorney General witness Sebastian Coppola, Michigan Environmental Council ("MEC") and Sierra Club ("SC") (collectively, MEC) witnesses Alice Napoleon and Dr. Sol deLeon, Citizens Utility Board of Michigan ("CUB") witnesses Richard J. Bunch and Joshua W. Denzler.

Q. Are you sponsoring any exhibits with your rebuttal testimony?

A. Yes, the following exhibit is sponsored with my rebuttal testimony:

Exhibit A-133 (NPD-2) Confidential	Discovery Responses U21806-MNSC-CE-0039, 0066, 0573, and 0771 with Attachments.

Q. Were these exhibits prepared by you or under your supervision?

A. Yes.

I. ATTORNEY GENERAL WITNESS COPOLLA

Q. On page 14, lines 18 through 20, of his direct testimony, Attorney General witness Coppola states that the Company is investing in the gas system as an opportunity to accelerate rate base growth to increase earnings growth. Is this accurate?

A. No, it is not. The Company's investments and the focus of the NGDP, Exhibit A-42 (NPD-1), are founded on the Company's commitment to providing a safe, reliable, affordable, and clean natural gas system for the people of Michigan. The capital

investments are made by the Company to ensure safety and reliability for its natural gas customers and to prevent incidents like those experienced by other operators in recent years. The NGDP, and the Company's investments, were developed by the Company's engineers. Planned work undertaken in gas distribution, transmission, compression, and storage are discussed in my direct testimony and in the direct testimony of Company witnesses Timothy K. Joyce, Kristine A. Pascarello, Lincoln D. Warriner, James P. Pnacek, and Michael P. Griffin. The comprehensive NGDP discusses the investments the Company is making, the reasons for the investments, the benefits of these investments, and considers the cost of these investments to customers.

Q. On page 15, lines 14 through 18, of his direct testimony, Attorney General witness Coppola states that the gas utility forecasts to spend $20 billion in capital over the next five years. Is this accurate?

A. No. As shown in Exhibit A-42 (NPD-1), the proposed five-year plan shows approximately $5.5 billion in proposed capital spending, not $20 billion.

Q. On pages 16 and 17, lines 4 through 9 and 2 through 10, respectively, of his direct testimony, Attorney General witness Coppola states that capital spending will pose a significant burden on residential customers and business bills. Is this accurate?

A. No. As discussed in Exhibit A-42 (NPD-1), the Company is committed to a bill growth rate at or below inflation and below the average rate of other gas utilities in the Midwest. Despite a historical 12% increase in rate base over the past 10 years, as described by Mr. Coppola, customer bills have shown a continuous annual growth rate ("CAGR") of -0.60%, which shows bills have actually decreased over the same period. Note, this is well

below Consumer Price Index of 2.80%[1] over the same period. When adjusted for inflation, customer bills decreased in real terms by approximately 4% per year compared to other goods and services making it a smaller component of a household's overall spend. In fact, data shows the average residential gas bill is approximately 1% of Michigan household income, considerably below other necessities such as transportation and cellular communication, 15% and 2%, respectively.[2] It is important to note that an increase in rate base does not necessarily correlate to an increase in bills as demonstrated above. Furthermore, the Company is committed to helping customers use less natural gas through energy efficient solutions and helping low-income customers through the Consumers Affordable Resource of Energy ("CARE") Program. These programs are discussed by Company witness Byrom.

Q. How does the Company's residential bill affordability compare to gas utility peers in the Midwest?

A. The Company benchmarks residential bills against Midwest gas utilities who experience similar climate conditions. Over the past five years, the Company has maintained a monthly residential bill below the Midwest average by approximately 24%. Additionally, the rate of bill growth is also below the Midwest average. Specifically, over the past five years, the Company's residential bills grew 1.4% less than the Midwest average. This is due in part to the Company's storage capabilities where natural gas can be purchased in

[1] U.S. Bureau of Labor Statistics. (2024). Consumer Price Index Summary. Retrieved from https://www.bls.gov/regions/midwest/data/consumerpriceindexhistorical_detroit_table.pdf.

the summer at a lower rate, stored, and then sold to customers in the winter at the same price.

II. CUB WITNESS BUNCH

Q. On page 6 of his direct testimony, CUB witness Bunch asserts that the proposed 12% rate increase is much higher than expected inflation. Is this accurate?

A. No. The proper comparison to inflation is the actual rate per mcf customers pay on their bill. Over the past 10 years, the Company's residential rate per mcf shows a CAGR of 1.38%, well below the rate of inflation over the same period at 2.80%.[3] As described above, when adjusted for inflation, residential customers saved on their natural gas bill compared to other goods and services included in the Consumers Price Index.

Q. On page 9, lines 6 through 10, of his direct testimony, CUB witness Bunch asserts that the proposed spending plan would severely impact residential rates, driving them by 158%. Is this accurate?

A. No. As shown in the Natural Gas Delivery Plan over the next 10 years, the Company expects an approximate 4.7% CAGR in residential bills, which is approximately the rate of inflation over the past five years. This projected increase equates to a cumulative 67% increase, not 158%. Additionally, increases assume relatively flat natural gas load over the next 10 years. Given the projected energy increases in the future, increased natural gas use in power generation and industrial development will potentially offset bill increases to a certain extent.

[3] U.S. Bureau of Labor Statistics. (2024). Consumer Price Index Summary. Retrieved from https://www.bls.gov/regions/midwest/data/consumerpriceindexhistorical_detroit_table.pdf.

III. MEC WITNESS DENZLER

Q. On pages 4 and 5, lines 6 through 13 and 11 through 18, respectively, of his direct testimony, MEC witness Denzler asserts that the proposed spending plan would severely impact residential rates, driving them by 158% and will be "super-inflationary." Is this accurate?

A. No, it is not. See my response to CUB witness Bunch on in Section II.

Q. On page 6, lines 3 through 14, of his direct testimony, MEC witness Denzler asserts that natural gas demand is not certain, leading to stranded costs in the future. Is this accurate?

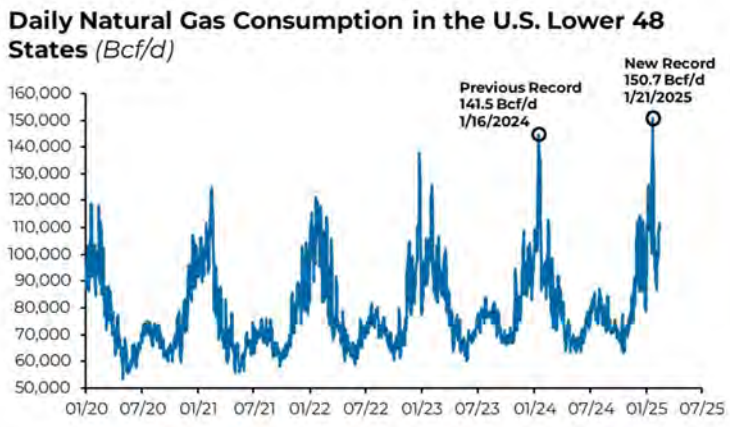
A. No, it is not. Data shows that the natural gas system is critical to Michigan's energy future from a low cost, customer, and energy capacity perspective. Regarding low-cost, natural gas is by far the least cost energy source for Michigan. The table below demonstrates this by comparing various energy costs on a $/MMbtu basis using the recent Company gas residential rates, Michigan average electric residential rates, and Michigan propane rates. For example, using the recent Michigan average electric rate of $0.1921/KWh, the conversion to MMbtu would equate to $56.30/MMbtu, showing over a 5x increase in commodity cost versus natural gas. It is clear all other fuels are considerably more expensive than natural gas.

	$/Mmbtu
CE Natural gas	$10.30
Propane	$25.36
MI Electric rate	$56.30

From a customer perspective, when asking gas customers "how do you feel Consumers Energy should prioritize each of the following as they plan for the future?"

with the ability to rank the options of "reliability," "affordability," and "sustainability," 48.9% rated reliability as a first priority for the Company. 41.2% of gas customers ranked affordability as a second priority, with 35% ranking affordability as the first priority. This tells us that natural gas is preferred as an exceptionally reliable and affordable energy source that will not only remain stable in the future but enable quality of life supported by low cost natural gas.

Lastly, the natural gas infrastructure provides significant energy capacity for Michigan. Recent climate trends, shown below, continue to set natural gas daily consumption records when cold snaps occur. During these peak conditions, the combination of space heating demand with lower output from renewables during winter months allow natural gas generators to fill demand. These spikes in demand highlight the critical importance of gas system capacity in delivering heat on the coldest days and fuel for potential future gas generation.



IV. MEC WITNESS DELEON

Q. On pages 10 and 11, lines 19 through 23 and 1 through 4, respectively, of her direct testimony, MEC witness deLeon asserts that natural gas assets will become stranded due to the energy transition. Is this accurate?

A. No. In addition to the responses above to CUB witness Bunch, analysis shows the gas system infrastructure will become more critical from the perspective of the energy transition. As described in Exhibit A-133 (NPD-2) Confidential, which is a packet of discovery response that the Company provided to MEC which includes discovery response U21806-MNSC-CE-0066, the retirement of coal generation and high cost of nuclear indicates natural gas will likely serve as a reliable, low-cost, baseload fuel for the significant growth in future energy demand through gas generation. Additionally, the gas distribution system enables cost effective heating that mitigates an otherwise 40% additional electric load for winter heating if end uses were electrified. Accordingly, gas distribution reduces the need for investment in electric generation and infrastructure by ~$20-25 billion.

Q. On page 14 of her direct testimony, MEC witness deLeon questions the effectiveness of the Renewable Natural Gas ("RNG") Program to contribute to the Company's greenhouse gas emission reduction goal. Is this a concern?

A. No. Customers have shown significant interest in the Company's RNG product, concentrated in the large industrial space. With most customer voluntary goals around the 2030 timeframe, customers have indicated they do not want a natural gas decarbonization solution until they need it, further emphasizing customer's priority around cost. Total expressed interest well exceeds the Company's available production emphasizing the need

to potentially expand the Program in the future. Customers show high interest in RNG because it is the least cost clean fuel alternative to natural gas, it is considered "drop-in" meaning no infrastructure modifications are required, the feedstock is readily available in Michigan, and it strongly supports the agricultural industry. Customer data aligns with the MI Healthy Climate Plan presumption that clean fuel alternatives like RNG are critical in decarbonizing high heat end uses.

Q. On page 17 of her direct testimony, MEC witness deLeon indicates the NGDP shows no evidence that the Company is pursuing non-pipe alternatives to meet its customer emission reduction goal. Is this true?

A. No. As described in the NGDP, the Company is actively investigating all potential carbon reduction pathways to meet the needs of customers in the future with an established framework. As demonstrated in Exhibit A-133 (NPD-2) Confidential, which is a packet of discovery response that the Company provided to MEC which includes discovery response U21806-MNSC-CE-0063 and U21806-MNSC-CE-0771, this framework includes maintaining a marginal cost abatement curve and long term modeling for a decarbonized future. The Company extensively collaborates with stakeholders around the industry to inform and validate modeling and analysis assumptions. Collaborations include other domestic and global peer utilities, the Low Carbon Resources Initiative, the H2EDGE Program, the MI Hydrogen Initiative, and the Midwest Alliance for Clean Hydrogen ("MachH2") hydrogen hub as an energy provider These collaborations are evident in the Company's work in network geothermal technology supported by the associated grant received from the Michigan Public Service Commission ("MPSC" or the "Commission"), along with the industry grant received to study synthetic gas production in Michigan using

green hydrogen. It is well understood through these collaborations that non-pipe alternatives that involve introducing new technologies raise cost for customers, and in some cases jeopardize the safety of the gas system. For these reasons, meeting customers' current and future needs is core to the NGDP. As described above, customers are most interested in reliable, low-cost energy, not more expensive non-pipe alternatives.

V. MEC WITNESS NAPOLEON

Q. On page 10, lines 10 through 13, MEC witness Napoleon indicates the decarbonization study by the Company is inconsistent with other studies performed. Is this true?

A. No. The Low Carbon Resource Initiative net-zero 2050 study, performed by the Electric Power Research Institute ("EPRI"), was used to test outputs of the Company led study, showing similar findings. Specifically, EPRI found that "Optionality enables affordability. Achieving economy-wide net-zero CO2 emissions while maintaining reliable delivery of energy and energy services across the economy will require a broad set of low-carbon technologies. An economy-wide, net-zero target with the flexibility to allocate positive and negative CO2 emissions allows each sector and region to follow their own decarbonization path while minimizing overall costs. Imposing greater limitations on resource and technology options could significantly increase the overall cost to achieve net zero emissions." This finding aligns with the Company's own study concluding that the balanced combination of multiple technologies such as energy waste reduction ("EWR"), RNG, carbon capture, hydrogen, and electrification will all be needed to cost effectively meet the State's 2050 net zero goal. The MI Healthy Climate Plan also supports the findings of the Company's decarbonization study demonstrating that no one pathway is viable to achieving the State's 2050 net zero ambitions. Additionally, the Company

performed the decarbonization study from an energy agnostic standpoint to truly understand the most effective way Michigan can decarbonize energy use. It was not in any way bias towards natural gas.

Q. On page 15 and 16, MEC witness Napoleon claims electrification can save costs by avoiding traditional infrastructure investments. Is this true?

A. No. The economics of electrification are based on the combination of technology capital costs, costs of energy, and technology efficiencies specific to geographic regions. The components are not mutually exclusive. As described above, if all customers electrified space heating, they would not only be impacted by an energy source 5x more costly than natural gas but also impacted by the cost of electric infrastructure buildout, estimated between $20-$25 billion. While forms of electrification can be highly energy efficient, they also have high upfront costs. Efficiency gains from electrification cannot make up for the up-front cost and disparity in energy cost. Regarding efficiency, electrified space heating efficiency drops considerably and consumes more energy in colder climates like Michigan, requiring supplemental heating. The Company agrees with Ms. Napoleon that energy efficiency and electrification go hand in hand. It is not practical to assume a heat pump can provide sufficient space heating without proper insulation. In fact, according to the American Community Survey, the median residential home in Michigan is 51 years old, up 4 years since 2014, indicating that homes are getting older. Older homes often do not carry sufficient insulation to take advantage of heat pump efficiencies. Additionally, as shown in Exhibit A-133 (NPD-2) Confidential, which is a packet of discovery response that the Company provided to MEC which includes discovery response U21806-MNSC-CE-0039 and U21806-MNSC-CE-0573, independent third party studies that conclude

reality for electrification in Michigan citing it is likely not cost effective due to climate and building retrofits required to realize benefits.

Q. On page 17, MEC witness Napoleon claims the Company is not assessing non-pipe alternatives. Is this true?

A. No. See my response above to MEC witness deLeon.

Q. On page 17, MEC witness Napoleon claims all non-pipe alternatives reduce emissions. Is this true?

A. No. It is industry standard to quantify emissions using lifecycle assessment measured in grams of carbon dioxide equivalent per megajoule ("gCO2e/MJ"). This measurement is called carbon intensity ("CI"). Natural gas shows an approximate CI of 80. Any fuel source below 80 is considered low carbon and contributes to emission reduction. On the contrary, any fuel above 80 increases emissions. Electrification and hydrogen technologies powered by the electric grid carry the emissions profile of the electric grid. According to real-time electricity maps at the time of this writing[4], the Midwest Independent System Operator, Inc. ("MISO") has a CI of 110, nearly 40% higher than conventional natural gas. This indicates that technologies powered by the electric grid like heat pumps and hydrogen electrolyzers actually emit more carbon than heating with natural gas today.

Q. On pages 25 and 26 of her direct testimony, MEC witness Napoleon claims gas consumption will decline in the future due to trends in electrification. Is this true?

A. No. As described by Company witness Warriner in his rebuttal testimony, trends in gas growth exceed electrification. Additionally, as described above, the cost of electrification

[4] Electricity Maps. (2025). Retrieved from Live 24/7 CO_2 emissions of electricity consumption | App | Electricity Maps.

in many cases for customers is considerably higher than natural gas. For this reason, the practicality of electrification in Michigan is limited.

Q. Does this conclude your rebuttal testimony?

A. Yes.

STATE OF MICHIGAN

BEFORE THE MICHIGAN PUBLIC SERVICE COMMISSION

In the matter of the application of **CONSUMERS ENERGY COMPANY** for authority to increase its rates for the distribution of natural gas and for other relief.	)))))	Case No. U-21806

REDACTED

EXHIBIT

OF

NEAL P. DREISIG

ON BEHALF OF

CONSUMERS ENERGY COMPANY

May 2025

Question:

34. Refer to page 82 of the NGDP where it states, "Consumers Energy is assessing where hybrid heating and heat pump technology can best serve customers."
a. Please provide details about any assessment the Company has conducted to-date.
b. Please provide all analysis, resources, and references behind this statement, including any supporting data and workpapers with formulas intact and all sources, assumptions, and units clearly identified.
c. Please describe the Company's plans for deploying or supporting residential and commercial hybrid heating through 2030 and through 2050.
d. Is the Company analyzing any full electrification technologies (heat pump technology without natural gas back-up)?
i. If so, please provide this analysis. In answering this question, please also provide data on:
1. The switchover temperature at or below which a hybrid heating system (combining a heat pump with a backup gas heating system) would rely on the backup gas heating.
2. The associated efficiency value, expressed as the coefficient of performance (COP), for the hybrid heat pump at that switchover temperature.
e. If the Company is not analyzing full electrification technologies, please explain how the Company can assess the benefits of hybrid heating and heat pump technologies relative to full electrification technologies.

Response:

a. The Company has not yet assessed where hybrid heating and heat pump technology can best serve customers but has evaluated the impact of heat pump technology with Michigan residents served by non-regulated fuels. Please reference U21806-MNSC-CE-0039_Dreisig_ATT_1 for completed impact evaluation on heat pump pilot study.
b. Attachments U21806-MNSC-CE-0039_Dreisig_ATT_1, U21806-MNSC-CE-0039_Dreisig_ATT_2, U21806-MNSC-CE-0039_Dreisig_ATT_3 and Appendix C – Decarbonization Modeling of the Natural Gas Delivery Plan are the analyses performed to date on heat pump technology.
c. The Company does not have current plans to deploy or support hybrid heating through 2030 and 2050. Customer research will continuously monitor behavior and preferences to assess the future need to support hybrid heating and heat pump technology.
d. The Company is currently evaluating geothermal technology through thermal energy networks in local communities. Please reference attachment U21806-MNSC-CE-0039_Dreisig_ATT_4 showing the Company's network geothermal proposal to the MPSC.
    i. The Company has not determined the optimum switchover temperature yet for network geothermal technology.
    ii. A coefficient of performance (COP) value is not evaluated at this switchover temperature; however, industry research suggests that network geothermal technology provides the highest COP of any electrification technology. Attachment U21806-MNSC-CE-0039_Dreisig_ATT_5 compares network geothermal against other heat pump pathways clearly showing the highest COP amongst alternatives. This is important because it may provide the most mitigation to incremental peak electric load during winter months in a highly electrified future.

e. As noted, the Company's gas business at this time is investigating full electrification through network geothermal technology.

Witness: NEAL P. DREISIG
Date: February 3, 2025

U21806-MNSC-CE-0066
Page **1** of **1**

Question:

61. Refer to the following statement on page 82 of the Natural Gas Delivery Plan: "Modeling shows the most cost-effective means of electrifying residential end uses is with hybrid heating. Hybrid heating combines the heat content of natural gas with the efficiency of a heat pump. In this context, heat pumps would be used as much as possible; however, during the coldest winter months, natural gas furnaces would still be used to mitigate winter peak electric load. Consumers Energy is assessing where hybrid heating and heat pump technology can best serve customers."

a. Please provide the Company's analysis for this modeling in MS Excel workbook.

b. Please provide a detailed plan for the assessment of hybrid heating.

Response:

a. The Company does not have modeling completed for hybrid heating in Excel format. Analysis for electrifying residential end uses with hybrid heating is based on third party consultant modeling that sought to achieve the combination of technologies that provided the lowest societal cost.

   Confidential Attachment U21148-MNSC-CE-0066_CONF_ATT_1 shows the analysis that demonstrates the balanced combination of multiple technologies will all be needed to meet the State's 2050 net zero goal at the lowest cost. This attachment will be provided to parties that have executed a non-disclosure agreement under the protective order. This analysis is a State level analysis using proprietary data modeling through third party expert consultants. The Company does not own, have a copy of, nor have access to the modeling program used.

b. Hybrid heating is anticipated to have high carbon abatement costs compared to other technologies but can help mitigate the shift of electric peak demand to winter. This approach could reduce the need for $20-25B in capital investment for electric generation and transmission infrastructure making it an overall affordable solution without impacting the existing system. Customer research will continuously monitor behavior and preferences to assess future need for hybrid heating technology.

Witness: NEAL P. DREISIG
Date: January 30, 2025

U21806-MNSC-CE-0573
Page **1** of **1**

Question:

8. Refer to U21806-MNSC-CE-0039 Attachment 2, slides 11 through 13.

a. Please provide all sources and assumptions behind the Company's estimate for the cost of "New gas furnace + installation" and "New ASHP + installation".

b. Please explain what the figures "Preferred technology based on trends assumptions" show.

i. What do the numbers on these figures indicate?

ii. What are the assumptions behind the 'current trends' and 'accelerated trends' scenarios?

Response:

a. Heat pump analysis details on U21806-MNSC-CE-0039 Attachment 2, slides 11 through 13, are based on proprietary data modeling through third party expert consultants. The Company does not own, have a copy of, nor have access to the modeling program used. The Company used U21806-MNSC-CE-0573_ATT 1 and U21806-MNSC-CE-0573_ATT 2 to verify cost estimates and conclusions shown on U21806-MNSC-CE-0039 Attachment 2.

b.

i. Numbers on the figures reflect the most likely electrification technology to be adopted given a "business as usual" environment vs. an environment where accelerated decarbonization trends exist. Natural gas is overlaid to better understand directionally when specific electrification technologies make sense for customers. In all cases, the "business as usual" trend shows natural gas as the most affordable option for customers. U21806-MNSC-CE-0573_ATT 1 and U21806-MNSC-CE-0573_ATT 2 studies confirm this.

ii. Assumptions behind "current trends" include the current state of federal and state policy along with current cost estimates and efficiency factors for various electrification technologies. In this scenario, natural gas is the most affordable option for customers. Assumptions behind "accelerated trends" include scenarios where climate policy is pulled forward requiring the accelerated adoption of various technologies.

Witness: NEAL P. DREISIG
Date: March 18, 2025

U21806-MNSC-CE-0771
Page **1** of **1**

Question:

5. Refer to MNSC-CE-0571 where it states, "Cost of carbon abatement is assessed through a marginal cost of carbon abatement framework. This assessment is performed annually by primary pathway to understand cost effectiveness of reducing carbon as standalone technologies. External cost impacts are excluded from assessment. This analysis provides directional cost effectiveness by pathway to help prioritize decision-making."

a. Please provide all workpapers and analysis used to assess the marginal cost of carbon abatement for each standalone technology and pathway, in excel format with formulas intact and all units and assumptions clearly identified.

b. Please provide the workpapers and results of the latest "directional cost effectiveness" analysis including all calculations used in the analysis in excel format with formulas intact and all units and assumptions clearly identified.

Response:

Objection of Counsel: Consumers Energy Company objects to this discovery request on the grounds that said request is not relevant to this proceeding. Consumers Energy is not requesting rate relief in this case related to carbon abatement in this proceeding. This request is outside the scope of the proceeding and does not appear to be reasonably calculated or necessary to gather any information that is important to the issues at stake in the case; thus, the request is not proportional to the needs of the case. S**ubject to the Company's objection and without waiving its objection, Consumers Energy responds as follows:**

a. Please find attached U21806-MNSC-CE-0771_ATT1, U21806-MNSC-CE-0771_ATT2, U21806-MNSC-CE-0771_ATT3, U21806-MNSC-CE-0771_ATT4.

b. Please find attached U21806-MNSC-CE-0771_ATT1.

TMY3	Typical meteorological year version 3

Executive Summary

In its March 5, 2020 Order Approving Settlement Agreement in Consumers Energy's *2020-2023 Energy Waste Reduction (EWR) Plan*, the Michigan Public Service Commission (MPSC) authorized the Company to invest in cold-climate heat pump (CCHP) initiatives for both income-qualified and non-income-qualified residential customers and business customers to test the efficacy, performance, and customer experience, among other factors. The Settlement Agreement[1] required the Company to submit an interim and final report delineating cold-climate heat pump (CCHP) initiative findings with the Company's 2020 and 2021 EWR Reconciliation filings, respectively. This report supplements the CCHP final report submitted as required by the March 5 Order and documents 2021 evaluation activities.[2]

The approved Settlement Agreement included both increased investment to support the income-qualified program performance metric associated with CCHP installations and a CCHP retrofit pilot initiative targeted to residential homes and businesses heated with electricity or heating fuels not regulated by the Michigan Public Service Commission, such as delivered propane or fuel oils. Given the challenges with implementing the CCHP initiatives, as well as unanticipated delays due to COVID-19, participation for income-qualified single-family and small commercial customers in 2021 occurred late in the year. This late participation has delayed the evaluation impact analysis for these two initiatives. All impact evaluation efforts will be completed in 2022 and the report will be filed in the case docket.

The main objective of these CCHP Initiatives was to demonstrate the potential for energy savings by replacing inefficient heating and cooling equipment with CCHPs. Consumers Energy targeted four distinct customer groups:

- Residential customers with electric or delivered fuel heating
- Income-qualified single-family customers with electric or delivered fuel heating
- Income-qualified multifamily customers with electric heating
- Small commercial customers with electric or delivered fuel heating

Consumers Energy designed its CCHP Initiatives to address both the supply and demand for CCHPs. The initiatives were implemented through Consumers Energy's existing residential, income qualified and small business product offerings. They aimed to strengthen trade allies' capabilities to install and service advanced heat pumps while increasing customers' awareness of and confidence in heat pumps as a viable, affordable, and environmentally friendly home heating source.

The CCHP Initiatives' incentives varied by customer type and ranged from $1,000 for market-rate customers to the full cost of installation for income-qualified and small business customers.

[1] Original settlement agreement: https://mi-psc.force.com/sfc/servlet.shepherd/version/download/068t0000009hu1HAAQ at page 2
Settlement agreement amendment: https://mi-psc.force.com/sfc/servlet.shepherd/version/download/068t000000CGUIcAAP

[2] Cadmus. 2020-2021 Cold-Climate Heat Pump Initiatives Final Report. May 18, 2022.

Consumers Energy marketed the initiatives through participating contractors, who were familiar with heat pump technology and had been educated about the offering, as well as through mass marketing campaigns and other Consumers Energy network partners like Habitat for Humanity. Table 1 through Table 3 shows participation and investments through December 31, 2021, by customer group and year.

Table 1. 2020 and 2021 Cold-Climate Heat Pump Participation and Investment

	Residential Market Rate	Income Qualified		Small Commercial	Total
		Single-Family	Multifamily		
2020 - 2021 Target	50 [a, b]	160	558	25 [b]	**793**
2020 - 2021 Installations	53	179	663	26 [c]	**921**
Percentage of Target	106%	112%	119%	88%	**116%**
Total Investment	$579,297	$3,184,143	$3,664,670	$999,000	**$8,427,110**

[a] The original Settlement Agreement targeted 100 heat pumps. Per the end of July 2020 reforecast; this was adjusted to 50 heat pumps.

[b] While the income qualified targets are specific to each year and summed in this table, the residential market rate and small commercial targets represent the total adjusted targets for the two-year period.

[c] This is updated from the 2020–2021 Cold Climate Heat Pump Initiatives Final Report.

Table 2. 2020 Cold-Climate Heat Pump Participation and Investment

	Residential Market Rate	Income Qualified		Small Commercial [a]	Total
		Single-Family	Multifamily		
2020 Target	100 [b]	100	225	25	**450**
2020 Installations	5	78 [c]	276	0	**359**
Percentage of Target	5%	78%	123%	0%	**80%**
2020 Investment	$258,771	$1,447,290	$1,523,558	$225,204	**$3,454,823**

[a] The small commercial initiative had eight commitments with three customers at the end of 2020, but no completed installations.

[b] The original Settlement Agreement targeted 100 heat pumps. Per the end of July reforecast, this was adjusted to 50 heat pumps.

[c] Of the 78 heat pumps, 74 were installed for a large group of duplexes owned by one landlord. Duplexes are classified as single-family homes.

Table 3. 2021 Cold-Climate Heat Pump Participation and Investment

	Residential Market Rate	Income Qualified		Small Commercial	Total
		Single-Family	Multifamily		
2021 Target	50	60	333	25	**468**
2021 Installations	48	101	387	26 [a]	**562**
Percentage of Target	96%	168%	116%	112%	**120%**
2021 Investment	$320,526	$1,736,853	$2,141,112	$773,796	**$4,972,287**

[a] This is updated from the 2020-2021 Cold-Climate Heat Pump Initiatives Final Report.

In addition to persistent market barriers to the adoption of CCHPs documented in the first-year summary of pilots, the Settlement Agreement imposed eligibility restrictions for Consumers Energy CCHP initiatives, requiring heat pump systems to displace at least 50% of a customer's heating load from delivered fuels or electric resistance heating systems and limiting residential eligibility to primary residences only (i.e. secondary or vacation homes were ineligible).

Consumers Energy continued to encounter several challenges with encouraging heat pump adoption across all income levels and all residential and multifamily building types. These challenges resulted in lower participation than expected and are attributed to a lack of consumer awareness, difficulty identifying eligible customers, lack of contractor participation, and, in some cases, high incremental costs. Consumers Energy encountered fewer challenges with small business owners given that the Initiative covered the full installation cost of the CCHP, but Consumers Energy recognizes this is not a sustainable program option and expects to encounter similar challenges as the residential market when the incentive no longer covers the full equipment and installation cost for customers.

Despite these challenges, participants were generally satisfied with their experience and gave high satisfaction ratings for the overall performance of their new heat pump. Participants also reported better working equipment and increased comfort compared to their previous equipment. In addition, the Evaluation team's impact analysis for market rate and income-qualified multifamily customers show most participants will save energy, and in turn, money on their heating and cooling bills; however, the ranges of savings vary based on the heating fuel type of the replaced equipment. An engineering analysis for income-qualified single-family customers and metering analysis for small commercial customers is currently underway and will be completed by end of 2022.

Consumers Energy contracted with independent teams led by Cadmus and TRC to evaluate its respective residential and commercial program portfolios (referred to jointly as the Evaluation team throughout this report). The Evaluation team focused on providing Consumers Energy with the necessary details to inform later phases of the CCHP Initiatives and on monitoring early performance in 2021 to comply with the evaluation and reporting requirements in its Settlement Agreement.

Research Objectives

The Cadmus team focused our evaluation on providing Consumers Energy with the necessary details to inform later phases of promoting CCHPs. Following discussions with Consumers Energy's program management staff, the Cadmus team identified several research objectives regarding the evaluation.

Cadmus assessed four research objectives:

Assess the CCHP Initiatives' performance according to energy savings, customer satisfaction, impacts to customer bills, operational issues, and customer comfort.

Understand market readiness to adopt heat pump technology on a large scale and learn about the challenges of installing CCHPs.

Determine current limitations in the CCHP supply chain and their potential implications for the CCHP Initiatives.

Understand how CCHPs impact low-income customers and property managers who own income-qualified housing on non-energy factors such as changes in energy bills, heating and cooling equipment operation, and comfort levels.

Research Approach

Starting in 2021, the Evaluation team conducted several research and evaluation activities:

- Interviews with Consumers Energy CCHP Initiatives managers and implementation contractors (n=7)
- Interviews with HVAC contractors, distributors, and CCHP manufacturers (n=18)
- Billing analysis, engineering reviews, site visits, and metering for commercial participants (n=9)
- Surveys or interviews with Initiative participants and property owners (n=51)
- Residential Market Rate Participant Engineering Analysis (n=51)
- Multifamily and Income Qualified Billing Analysis (n=77 participants and 112 comparison buildings)

Participation was limited across all initiatives. This meant there were small populations to survey, interview, and perform billing analysis activities even using the census of participants. Therefore, the generated results, in most cases, are not statistically significant and while the evaluation team has made some conclusions and recommendations in this report, there is remaining uncertainty about the technology performance and market potential of CCHPs in Michigan. In addition, participation for small business customers occurred later in 2021, which delayed the metering of small business CCHPs.[3] Results from this activity will be prepared for Consumers Energy in Q4 2022.

Report Organization

We organized this report as follows:

- Summary of Key Findings, Conclusions, and Recommendations
- Contractor, Distributor, and Manufacturer Findings
- Residential Market Rate Initiative Findings
- Income Qualified Multifamily Initiative Findings
- Commercial and Industrial Cold-Climate Heat Pump Pilot Findings
- Appendices
  - Appendix A: Survey and Interview Methodology and Details
  - Appendix B: Impact Analysis Methodology and Details
  - Appendix C: Consumers Energy Heat Pump Market Rate Customer Survey
  - Appendix D: Consumers Energy Heat Pump Property Owner and Manager Interview Guide
  - Appendix E: Consumers Energy Heat Pump Multifamily Tenant Survey Guide
  - Appendix F: Consumers Energy Heat Pump Commercial Interview Guide
  - Appendix G: Consumers Energy Heat Pump Contractor Interview Guide
  - Appendix H: Consumers Energy Heat Pump Manufacturer and Distributor Interview Guide

[3] Initial impact analysis for commercial customers is reported in " 2021 Cold Climate Heat Pump Pilot Impact Evaluation Results Memo submitted to Consumers Energy by TRC. Updated cooling savings will be provided at the conclusion of additional metering in November 2022.

Summary of Key Findings, Conclusions, and Recommendations

This section presents the Evaluation team's key research findings, conclusions, and recommendations associated with the four cold-climate heat pump (CCHP) research objectives, which informed our evaluation tasks. The remaining chapters of this report provide further explanation of these findings and support for our conclusions and recommendations.

Key Findings and Recommendations

CONCLUSION 1. There is low and varied awareness of cold-climate heat pumps by homeowners, property owners and their tenants, and commercial businesses and even lower awareness that Consumers Energy offers cold-climate heat pump rebates.

Participants' awareness of CCHPs and Consumers Energy rebates was largely driven by HVAC contractors and Consumers Energy. However, awareness varied among contractors and within the territories they served. Where contractors were aware of CCHPs, they were a driving force of information dissemination about heat pumps and Consumers Energy rebates for both residential and commercial customers.

TRADE ALLIES: Contractors' overall awareness of heat pump technologies was largely correlated with the heating fuels used by their customer base. Contractors serving rural populations (where delivered fuels are more common) were more familiar with ducted heat pump systems, while contractors serving urban populations (where electric resistance heating is more prevalent) were more familiar with ductless heat pump systems. Contractors indicated that Consumers Energy could be instrumental in driving awareness of heat pump technologies, citing the success of the campaigns used to promote smart thermostats.

MARKET RATE: Most Residential Market Rate pilot participants reported being familiar with CCHPs before deciding to purchase one for their home (eight of nine), but few (three of nine) were aware that Consumers Energy provided heat pump rebates. While CCHP rebates were new in 2020, respondents' awareness of heat pumps came primarily from contractors, with about half (five of nine) indicating that a contractor had recommended a heat pump before they learned about and applied for the Consumers Energy heat pump rebate. A small number of participants (two of nine) heard about the rebate through Consumers Energy email communications.

INCOME QUALIFIED MULTIFAMILY: Multifamily property owners and managers were generally aware (31%, or n=10 of 32) of CCHPs prior to being approached by Consumers Energy, though they were not aware of Consumers Energy incentives until their involvement. However, the property owners and managers' tenants reported a lack of knowledge regarding heat pumps, with 66% of tenant respondents (n=21 of 32) saying they did not know about CCHPs, and half saying they were not aware that there was a CCHP installed in their apartment at the time of the survey. Of the half that were aware of the heat pump installation, 56% (n=9 of 16) did not know that Consumers Energy was involved in the project.

COMMERCIAL: Only two out of seven interviewed commercial respondents were familiar with cold-climate heat pump technology prior to participation. Those who had heard of cold-climate heat

pumps were unaware of the advancements in technology that made heat pumps more feasible for regions, like Michigan, with very cold winters. After learning about the new cold-climate heat pumps and Consumers Energy's pilot, most respondents were motivated to participate, but still held reservations about performance during the winter, prompting some to ask to keep their old heating system as a back-up.

RECOMMENDATIONS

High Priority: Identify opportunities for Consumers Energy to promote the cold-climate heat pump technology and incentives. Consider providing materials, such as one-page initiative summaries, for distributors to leave with contractors during their interactions. Continue to promote cold-climate heat pumps through events like the Annual Trade Ally Kickoff or identify larger distribution events or trainings where Consumers Energy can interact with trade allies.

High Priority: Increase contractor and customer education of cold-climate heat pump benefits and technology. Consider increasing the promotion of cold-climate heat pumps through planned marketing campaigns (such as bill inserts and online advertising) and through cross-program promotions.

CONCLUSION 2. Because natural gas is the predominate heating fuel in Michigan, and current Michigan Public Service Commission policy limits fuel-switching, there are limited cost-effective cold-climate heat pump installation opportunities. This contrasts with other states such as Maine and Vermont where a higher percentage of homes use more costly heating fuels such as propane and oil and where state policies incentivize fuel-switching.

TRADE ALLIES: While demand is increasing, trade allies reported that multiple barriers have limited demand for CCHPs in Michigan compared to other states. Manufacturers and distributors noted that awareness of and affinity for CCHPs among contractors varied and some maintain the belief that heat pumps are not effective in cold climates. Contractors and distributors also reported that increased customer awareness would help increase adoption; however, the cost of new CCHPs remains prohibitive. A homeowner likely needs to financially benefit from switching to a CCHP to be interested, but the lifecycle cost of a new CCHP compared to alternative heating technologies supplied by natural gas (the predominate heating fuel in Michigan) likely does not financially benefit the homeowner at a time when natural gas rates are low. Contractors acknowledged this fuel-switching challenge and said that even when they identify a potential cold-climate heat pump customer, there are few tools available for the contractor or customer to make accurate projections of the total system lifetime cost savings.

MARKET RATE AND COMMERCIAL CUSTOMERS: During 2021 and 2022, the Michigan Public Service Commission allowed Consumers Energy to target market rate and commercial customers who receive non-regulated fuels and those with electric heating systems. Consumers Energy's *2018 Residential Appliance Saturation and Home Characteristics Study* found that approximately 82% of customers in single-family homes across Consumers Energy's natural gas, electric and combination fuel

service territory heat their homes with natural gas, while 4% use electric heat and 14% use another source such as propane, fuel oil, or wood. This heating fuel distribution creates a significant challenge with identifying homeowners and businesses that may be eligible for a CCHP under the current regulatory rules (i.e., heat their homes or buildings with electric or distributed fuels), and limits market potential. Of the residential market rate participants for which baseline analysis was conducted (n=51), the majority (59%) used propane or oil, while 31 % used electric heat and 10% used natural gas heat prior to installing their heat pump[4].

Four of the seven commercial respondents interviewed discussed wanting to move away from using propane, and two of the respondents were motivated to participate in the pilot specifically so they could stop using propane. While respondents appreciated the opportunity to move from propane to electric heating, it is unclear whether Consumers Energy can continue with this targeted approach beyond the pilot phase. Future negotiations between the Michigan Public Service Commission and Consumers Energy and its stakeholders will determine whether Consumers Energy can continue to rely on this targeted approach in future initiative cycles.

RECOMMENDATIONS

High Priority: Because contractors reported that it is not always simple to determine when cold-climate heat pumps are economically more beneficial than traditional equipment, provide them with sales tools, such as a cost-effectiveness calculator, that can assist them in identifying when a cold-climate heat pump makes financial sense for their customers.

Low Priority: Promote the space cooling benefits associated with a cold-climate heat pump. Cold-climate heat pumps are a good option to add cooling where there was not previously a whole-home space cooling system or where the cold-climate heat pump can replace inefficient central air conditioners and room air conditioners.

CONCLUSION 3. Participants were generally satisfied with their experience and gave very high ratings for the CCHP Initiatives offering. However, multifamily tenants' satisfaction was split, largely based on whether the tenant received education on how to operate the new equipment.

MARKET RATE: Market rate customers gave high satisfaction ratings, with all nine respondents giving a rating of 8 or higher for their overall experience with the heat pump. In addition, market rate customers were highly likely to recommend the heat pump to a friend (with a net promoter[5] score of +89).

[4] Consumers Energy excluded most customers that used natural gas for space heating from the CCHP initiative, but a small number of participants recruited by contractors used natural gas prior to installation of the CCHP.

[5] The net promoter score is expressed as an absolute number between -100 and +100 that represents the difference between the percentage of promoters (respondents giving a rating of 9 or 10) and the percentage of detractors (respondents giving a rating of 1 to 6).

INCOME QUALIFIED MULTIFAMILY: The three interviewed income qualified multifamily property owners and managers provided an average rating of 9.5 (on a 10-point scale) for their satisfaction with the CCHP Initiatives and their likelihood to recommend heat pumps to a colleague. The property owners and managers also rated their likelihood to adopt similar CCHP equipment in their other properties as a 9.0 on a 10-point scale.

Income-qualified multifamily tenants (n=23 of 32) were *very satisfied* with their CCHP experience, and generally felt that the heat pumps provided improved winter heating and summer cooling comfort. Multifamily tenant participants gave an average rating of 8.7 for their overall experience with the heat pump, though some may not have been aware of their heat pump until they were contacted for the survey. Respondents also gave an average rating of 8.8 regarding summer comfort and 7.9 regarding winter comfort. However, tenants' willingness to recommend Consumers Energy was dependent on the level of communication and instruction provided to them regarding equipment operation. Tenants who provided verbatim feedback around lack of instruction were more likely to provide a lower overall net promoter score (averaging +13) than those who received instructions (averaging +50). Similarly, tenants who reported that the installer did not set up their heating and cooling schedule were also more likely to provide a lower overall net promoter score (averaging +10) than those who had the installer set up a schedule (averaging +67).

COMMERCIAL: Commercial participants rated their overall satisfaction with the CCHP Initiatives as an average of 9.9 out of 10, and 86% (six out of seven interviewees) strongly agreed that Consumers Energy made it easy to participate in the initiative.[6] In follow up interviews with participants, four out of five interviewees reported being satisfied with their heat pump's performance during the winter.[7]

CONCLUSION 4. Some participants received a new thermostat with their CCHP. Participants who received a new thermostat had varied knowledge about how to use it to optimize operation of their heat pump and some could have benefitted from additional instructions and training.

MARKET RATE: Seven of the nine residential market rate participants had a programmable or smart thermostat, while two reported having a non-programmable thermostat. Of those who had a programmable thermostat, only two programmed temperature setbacks. Despite most having thermostat programming capability, four of nine tended to adjust the temperature manually.

INCOME QUALIFIED MULTIFAMILY: Only three income qualified multifamily respondents could confirm with certainty that the contractor set up a heating and cooling schedule for their heat pump. These three participants also confirmed that the heating and cooling schedule set up by the

[6] Commercial participants were interviewed prior to experiencing a full heating season and some respondents listed this uncertainty about how the equipment would perform during the heating season as a reason for not giving a higher satisfaction rating for their heat pump, though the average rating was still 9.3 out of 10.

[7] The one respondent who was displeased, noted that the heat pump took a while to turn on, they often felt a cool breeze that was discharged directly onto an employee, and they had to adjust their thermostat higher than usual in order to achieve their preferred temperature.

contractor was still in operation. Only 25% (n=8) reported receiving instructions or documentation about the heat pump or use of their thermostat with the heat pump.

COMMERCIAL: Most respondents needed additional time to learn how to use their new thermostats and a few had minor issues operating their heat pumps. While most respondents did not have any problems with their new heat pumps, some (43%; n=3) reported that learning how to use their new thermostat was the most challenging aspect of their new equipment. Two respondents (29%) also reported needing a contractor's assistance with minor issues related to operating their heat pump. These minor issues included resolving an installation error and adjusting the cooling so that the air temperature was reaching the thermostat's temperature setpoint. Another finding from the follow up interviews was that some customers needed additional support understanding the controls and settings of the heat pumps to maximize the value, especially when sites have overlapping building controls with multiple heating units.

RECOMMENDATION

High Priority: Consider increasing follow up communications and support after the installation to ensure participants understand their new technology. Sending follow-up emails with resources and providing high-touch support after the installation engenders a positive equipment experience, which is critical for word-of-mouth testimonial marketing. Encourage contractors to provide set up and programming instructions and provide contractor training to ensure they are familiar with different types of thermostats and systems.

CONCLUSION 5. Participants reported better working equipment and increased home and business comfort levels after the installation of their CCHP.

MARKET RATE: Most market rate participants surveyed (seven of nine) said their home was more comfortable after installing the heat pump. The nine respondents rated their comfort level as 9.1 on average during the summer, with a slightly lower rating of 8.6 (n=5) during the winter. None of the respondents indicated any concerns with the heat pump's ability to heat to a preferred comfort level. Five respondents also mentioned improved heating and cooling distribution across sections of the home.

INCOME QUALIFIED MULTIFAMILY: Income-qualified multifamily tenants said their homes were as comfortable with the CCHPs as before (43%), with one-quarter reporting increased comfort levels. A few tenants said their home was too hot or too cold after the heat pump installation. Property owners and managers indicated that tenant comfort was a key decision factor to install CCHPs.

COMMERCIAL: Customers were very satisfied with heat pump performance overall , though three interviewees (43%) reported some minor initial issues with their heat pumps, including one who said it did not cool down to the expected temperature and two who had issues with the installation that required a contractor to fix.

RECOMMENDATION

Medium Priority: Promote the increased home and business comfort that cold-climate heat pumps can provide during both the heating and cooling seasons. Developing and using home and business testimonials could be an effective way Consumers Energy can promote the benefits of cold-climate heat pumps such as increased comfort, lower energy bills, and for some, the addition of space cooling.

CONCLUSION 6: Distributors generally had heat pump inventory on hand, so delivery times were either not impacted or were only impacted temporarily by manufacturing delays.

While manufacturers and distributors reported manufacturing delays as a result of COVID-19, as well as on-going transportation delays, distributors generally reported having sufficient stock on hand to meet current demand. Only one distributor reported a delay (6 to 8 weeks) in getting equipment to the customer. Note that custom equipment was generally not discussed in the interviews with manufacturers and distributors, and it is possible that timelines for custom equipment could be different. It is also worth noting that the manufacturer and distributor interviews were conducted in April of 2021, and the factors influencing supply chains may have changed since this time.

CONCLUSION 7: Most residential market rate and income-qualified Multifamily participants realized heating and cooling utility bill savings after the installation of their CCHP. However, bill savings largely depends on heating fuel prior to the heat pump installation, as well as how the homeowner used their new equipment.

MARKET RATE: The majority of market rate participants replaced propane heating systems (51%), followed by electric heating (31%), natural gas heating (10%), and fuel oil heating (8%).[8] Based on engineering estimates, market rate participants who replaced propane or electric heating systems will realize approximately $910 to $1,680 in heating and cooling savings per year[9]. The five homes that previously heated with natural gas will likely see an increase in their utility bill of $450 per year on average due to the higher cost of electricity compared to natural gas; also, four of the five homes did not have existing central air conditioning, which means they will add electrical load in the summer.

INCOME QUALIFIED MULTIFAMILY: Income-qualified multifamily tenants, even though retaining their original baseboard heating systems, experienced annual savings of 896 kWh, which translates to approximately $147 in annual bill savings. Most of the savings (93%) were realized during the heating season (largely October-April). These savings during the heating season were equivalent to approximately 23% of baseline weather-sensitive electric heating use. Income qualified multifamily tenants experienced lower than anticipated savings attributable to the heat pumps because they continued use of their baseboard heating systems, consistent with other recent evaluation findings.

[8] At the time of conducting the engineering analysis the evaluation team had a sample of 51 CCHP installations.

[9] Based on fuel costs at the time of the analysis in January 2022.

INCOME QUALIFIED SINGLE FAMILY: Due to low participation and delays due to COVID, the Income Qualified Single-Family Impact analysis will be completed in 2022. The Evaluation team is currently conducting an engineering analysis of the impacts for the income-qualified single-family installations, relying on MEMD parameters and assumptions collected from customers such as home vintage, presence of central cooling, equipment efficiencies, tonnage, and other data. The analysis will be completed later in 2022 and filed in the case docket.

COMMERCIAL: Because participation in the small business pilot occurred later in 2021, the impact evaluation was delayed. The impact evaluation is based on metered data, and TRC is keeping the meters in place to collect data for at least one complete heating season and one complete cooling season for each site.[10] The results of the heating season impact analysis are presented in a separate memo that is included in the filing of 2021 studies made on August 31, 2022.[11] Metering for the 2022 cooling season is still in progress as of the writing of the report, and analysis will take place in later in 2022.

RECOMMENDATIONS

High Priority: Provide multifamily property owners who had cold-climate heat pumps installed with information for how continued use of baseboard heating systems will minimize the tenant's ability to achieve the highest potential heating, and cost savings.

High Priority: Provide multifamily property owners with handouts they can distribute to tenants with simple operational instructions to ensure all new tenants understand how to operate their heat pump systems. Additional follow up and coordination with maintenance staff to review proper operations would ensure persistence of heat pump savings.

High Priority: If the Michigan policy on fuel switching should change, natural gas heating customers should be screened prior to approval to ensure the heat pump has potential to reduce energy bills.

Table 4 shows the Evaluation team's conclusion for each research objective outlined above.

[10] Metering analysis was performed for 22 CCHP installations.

[11] TRC. 2022. C&I 2021 Cold Climate Heat Pump Pilot Impact Evaluation Memo

Table 4. Research Objective Mapping

Conclusion	Research Objective: 1. Assess Cold-Climate Heat Pump Initiative Performance	2. Understand Market Readiness and Challenges	3. Determine Current Supply Chain Limitations	4. Understand Impacts on Low-Income Customers
There is low and varied awareness of cold-climate heat pumps by homeowners, property owners and their tenants, and commercial businesses and even lower awareness that Consumers Energy offers cold-climate heat pump rebates.		✓		
Because natural gas is the predominate heating fuel in Michigan, and current Michigan Public Service Commission policy limits fuel-switching, there are limited cost-effective cold-climate heat pump installation opportunities. Recommendation Priority

To assist Consumers Energy in prioritizing the actions needed to address these recommendations, the Evaluation team organized each evaluation recommendation by topic and prioritized them based on the following definitions.

- ***High Priority:*** The evaluation revealed compelling and conclusive data on a concern or a current initiative strength that are likely to have a significant impact on customer satisfaction, achievement of participation goals, or initiative savings if not addressed or maintained.
- ***Medium Priority:*** The evaluation revealed data that are inconclusive and require additional investigation or the issue is likely to have a moderate impact on initiative effectiveness or efficiency.
- **Low Priority:** The issue is likely to have little impact on initiative effectiveness or efficiency.

Table 5 lists the CCHP initiatives evaluation recommendations.

Table 5. Summary of Heat Pump Pilot Recommendations and Priorities

Priority	Summary of Recommendations
High Priority	Identify opportunities for Consumers Energy to promote the Cold-Climate Heat Pump technology and incentives. Consider providing materials, such as one-page initiative summaries, for distributors to leave with contractors during their interactions. Continue to promote cold-climate heat pumps through events like the Annual Trade Ally Kickoff or identify larger distribution events or trainings where Consumers Energy can interact with trade allies.
	Increase contractor and customer education of cold-climate heat pump benefits and technology. Consider increasing the promotion of cold-climate heat pumps through planned marketing campaigns (such as bill inserts and online advertising) and through cross-program promotions.
	Because contractors reported that it is not always simple to determine when cold-climate heat pumps are economically more beneficial than traditional equipment, provide them with sales tools, such as a cost-effectiveness calculator, that can assist them in identifying when a cold-climate heat pump makes financial sense for their customers.
	Consider increasing follow up and support after the installation to ensure participants understand their new technology. Sending follow-up emails with resources and providing high-touch support after the installation engenders a positive equipment experience, which is critical for word-of-mouth testimonial marketing. Encourage contractors to provide set up and programming instructions and provide contractor training to ensure they are familiar with different types of thermostats and systems.
	Provide multifamily property owners who had cold-climate heat pumps installed with information for how continued use of baseboard heating systems will minimize the tenant's ability to achieve the highest potential heating and cost savings.
	Provide multifamily property owners with handouts they can distribute to tenants with simple operational instructions to ensure all new tenants understand how to operate their heat pump heating systems. Additional follow up and coordination with maintenance staff to review proper operations would ensure persistence of heat pump savings.
	If the Michigan Public Service Commission policy on fuel switching should change, natural gas heating customers should be screened prior to approval to ensure the heat pump has potential to reduce energy use.
Medium Priority	Promote the increased home and business comfort that cold-climate heat pumps can provide during both the heating and cooling seasons. Developing and using home and business testimonials could be an effective way Consumers Energy can promote the benefits of cold-climate heat pumps such as increased comfort, lower energy bills, and for some the addition of space cooling.
Low Priority	Promote the space cooling benefits associated with a cold-climate heat pump. Cold-climate heat pumps are a good option to add cooling where there was not previously a whole-home space cooling system or where the cold-climate heat pump can replace inefficient central air and room air conditioners.

Contractor, Distributor, and Manufacturer Findings

Consumers Energy launched the CCHP initiatives just prior to the start of the COVID-19 pandemic, which as reported by Consumers Energy staff, created unique challenges such as long delays in project timelines due to back-ordered equipment. In addition, trade ally participation was low, with only one trade ally completing the vast majority of installations across these offerings in the early months of the initiative. To determine the sources of these barriers and understand the challenges associated with adopting CCHPs in Consumers Energy's service territory, the Evaluation team interviewed eleven contractors, two manufacturers, and five distributors involved in the installation, production, and distribution of CCHPs in Michigan.

Contractors' awareness and perceptions of CCHPs varied, and a contractor's interest in heat pump technologies in general depended largely on the availability of different heating fuels in their service territories. Contractors in rural areas, where delivered fuels are more common, had more awareness of and a greater affinity for ducted systems and heat pumps in general. Contractors in urban areas had more awareness of ductless systems, but overall lower levels of familiarity with and affinity for heat pump technologies.

Among all contractors, the pervading theme regarding CCHPs (and heat pumps in general) is that of uncertainty. In order to confidently promote heat pump technologies, contractors must be able to determine the operating cost of the equipment compared to a customer's existing equipment. Currently, there are no readily available tools that allow contractors to accurately model and compare the energy consumption of a heat pump to other heating sources; combined with the comparatively higher up-front cost of heat pumps, this inability to accurately model potential energy savings commonly makes heat pumps a non-starter. Furthermore, several contractors expressed a hesitancy to promote electric heating sources to their customers, as they perceived the price of electricity to be less static and more prone to price increases than other fuel sources. Additionally, some contractors were unaware that CCHPs were effective in cold climates. The confluence of uncertainty around CCHPs is commonly too significant of a barrier for contractors to abandon the status quo of a like-for-like equipment replacement.

Although there were manufacturing and transportation delays, distributors reported having stock on hand that was sufficient to meet current demand. Manufacturers and distributors noted that some contractors maintained the belief that heat pumps were not effective in cold climates (a finding that may be correlated with a contractor's location, given that the contractor interviews found that contractors in urban areas were less aware and less in favor of heat pumps compared to those in rural areas). Aside from this contractor barrier, manufacturers and distributors pointed to customer hesitation due to large up-front or long-term costs associated with CCHPs. In Michigan, CCHPs are less cost-effective than in other states due to the low cost of natural gas, but demand seems to be increasing, especially in rural areas where homes are predominantly heated with propane or oil.

This chapter provides contractor findings separately from manufacturer and distributor findings.

Contractor Findings

The Evaluation team interviewed eleven HVAC contractors to address three research objectives:

- Determine current awareness and perceptions of heat pump technologies.
- Identify the main barriers to installing heat pumps in Michigan.
- Identify marketing and outreach best practices.

The key findings corresponding to each research objective are outlined below.

Cold-Climate Heat Pump Awareness and Perceptions

Contractors' overall awareness of and attitudes toward CCHP technologies were largely correlated with the type of fuel available to the contractor's customer base. Contractors serving rural populations were more familiar with ducted systems, displayed an overall greater affinity for heat pump technologies, and reported higher levels of customer awareness and demand. Conversely, contractors serving urban populations were more familiar with ductless systems and displayed comparatively lower levels of familiarity with improvements in CCHP capabilities.

Contractors indicated that general awareness of heat pump technologies among customers was low but increasing. Contractors reported a marginal increase in the number of customers asking for the technology in recent months, and a more substantial increase in customers who were aware once the contractor presents CCHPs as an option. Similarly with contractor awareness, customer awareness is largely correlated with location and the availability of natural gas.

> "The typical customer is not aware it [CCHPs] is a heating option."
> - Contractor

Best Cold-Climate Heat Pump Applications

Contractors detailed the various scenarios in which CCHPs are currently being adopted by customers, or where they make the most sense for future adoption. For ducted systems, contractors reported the three best applications:

- Customers with propane or delivered fuels who have no access to natural gas
- Green-motivated customers who are not as cost conscious
- New construction

The best applications for ductless mini splits differ by heating versus cooling:

- Heating
  - Customers with electric baseboard heat—especially multifamily customers
  - Customers with hot or cold spots not served well by the existing system (and who could use heat pumps for supplementary heat)
- Cooling
  - Customers with no existing duct work (such as those with a boiler or electric baseboard heat)
  - Commercial applications, such as computer server rooms or elevator rooms
  - Vacation homes (that are not occupied in the winter)[12]

[12] Note that secondary or vacation homes were not eligible for the pilot.

Barriers to Adoption

Contractors provided a variety of reasons for the relatively slow adoption of heat pump technologies to date. Barriers primarily relate to financial constraints, either the up-front cost of the equipment or the comparatively higher operating cost (where natural gas is available). Adding to concerns over the operating cost is the idea that electric rates can be somewhat variable, so even if a contactor is able to project the operating cost of equipment for their customer, there is no guarantee that the projection will be accurate in the future. Furthermore, even when projecting operating costs using a fixed cost of electricity, there are no readily available tools by which contractors or customers can make accurate projections of the total system cost (equipment and operation). Several barriers were identified:

- Higher equipment cost versus other systems
- Relative higher cost of electricity compared to natural gas
- Variability in electric rates
- Inability to make accurate comparisons between the operating costs of CCHP systems to traditional heating systems
- Lack of education and awareness for the public and contractors alike
- Contractor perceptions of poor performance in the Michigan climate (less common)

Installation complexity and cost, supply chain robustness, and previous experiences with heat pumps are not seen as barriers among contractors. Contractors detailed how heat pumps generally require minimal additional work compared to traditional systems, and that relative to the additional cost of the equipment itself, the additional installation costs are negligible.

> "ASHPs [air-source heat pumps] have fallen off [become less common] for a couple reasons: most homes lately have a natural gas option, so we feel it is more to their advantage to use the gas furnace than air-to-air heat pumps."
>
> - Contractor

Overcoming Barriers to Adoption

There was no consensus among interviewed contractors as to what would be most influential in increasing CCHP adoption. Two contractors referenced a different rate structure for customers who use electric heat: Consumers Energy used to offer a special rate for customers with electric heat, and one contractor said the number of heat pumps they install has decreased since this rate was rescinded. These contractors believe that introducing an electric heating rate would potentially help to price CCHPs more similarly to natural gas–fired systems and lead to increased adoption:

- "If you choose a certain heating system, they used to offer a heating energy price decrease. If Consumers [Energy] could bring something like this back, demand would explode. Offer special rates for HP [heat pump] use for heating."
- "Used to do heat pumps more when they offered an electric heating rate, but we've switched to mostly natural gas due to cost of use."

Two contractors indicated that additional customer education is necessary to increase CCHP adoption, with one proposing a potential marketing campaign similar to the thermostat promotions that Consumers Energy currently offers. Other suggestions included offering increased rebates and a tool that helps customers more accurately project the lifetime operating costs of heat pumps against other space heating options:

- "Messaging would be a big bonus for all the contractors. It would help with promoting them [CCHPs]. Like the thermostat promotions that have produced a lot of positive feedback, [a campaign promoting heat pumps] would be very helpful."
- "Just educating people about that they've gotten the bugs out of these things [CCHPs] and they're working great."
- "Better rebates on them [CCHPs] for sure. With the [heat pumps] we have had a hard time meeting Consumers Energy's rebate requirements to qualify; our basic ASHP [air-source heat pump] doesn't qualify [and would] need to get up into the second or third level of efficiency, and with the increased cost the low [$100] rebates are not effective."
- "[It would be great] if Consumers [Energy] were able to come up with a tool comparing purchase and operational costs of electricity versus natural gas systems, showing savings of switching over when customers have dual fuel systems."

Marketing and Outreach Suggestions

As previously noted, two contractors said that increased customer education would be the most impactful way to increase customer demand for CCHP technologies. Each interviewed contractor suggested specific comparisons or promotional strategies to present the equipment to customers:

- Two suggested direct promotional campaigns from Mitsubishi that have been successful within Michigan
- One suggested using smart thermostat promotions from Consumers Energy
- One suggested promoting heat pumps as an air conditioner (AC) that also provides free heat
- One suggested offering a winter electric heating rate for owners with a CCHP
- One suggested providing tools to demonstrate savings compared to other systems

Income-Qualified Considerations

Two contractors indicated that unique circumstances may prevent the widespread adoption of heat pumps for income-qualified customers:

- The potential for theft of the costly units
- Low-income property managers' aversion to potential equipment issues and ensuing repairs

Distributor and Manufacturer Findings

The Evaluation team interviewed five distributors and two manufacturers of CCHPs in Michigan to address several research objectives:

- Confirm and document the supply chain for CCHPs in Michigan
- Identify the barriers leading to extended timelines for CCHP installation
- Identify sources of differences in CCHP installation costs across states
- Explore the cause of low participation by trade allies
- Identify any additional barriers and challenges delaying the widespread adoption of CCHPs in Michigan, like training or education
- Identify ways in which Consumers Energy can influence market adoption

The key findings corresponding to each research objective are outlined below.

Cold-Climate Heat Pump Supply Chain

Manufacturers and distributors confirmed that CCHPs follow a traditional supply chain structure, with no difference compared to traditional air-source heat pumps (ASHPs) or other types of HVAC equipment. While this typically means that units move from the manufacturer to the distributor and then to a contractor before reaching customers, there are exceptions for national corporate customers, who may purchase equipment directly from a distributor rather than through a contractor (see Figure 1).

Many CCHPs are manufactured abroad and shipped to ports in the United States, primarily to California or Georgia, before being trucked to regional destinations.

Figure 1. Heat Pump Supply Chain

Installation Timelines

Distributors reported it takes from one to 20 weeks to receive inventory from manufacturers, depending on whether the manufacturer is overseas or domestic and whether they placed a rush order. Manufacturers and distributors reported experiencing manufacturing delays as a result of COVID-19, as

well as ongoing transportation delays that included backups at ports and a truck driver shortage that began in 2018, prior to the pandemic.

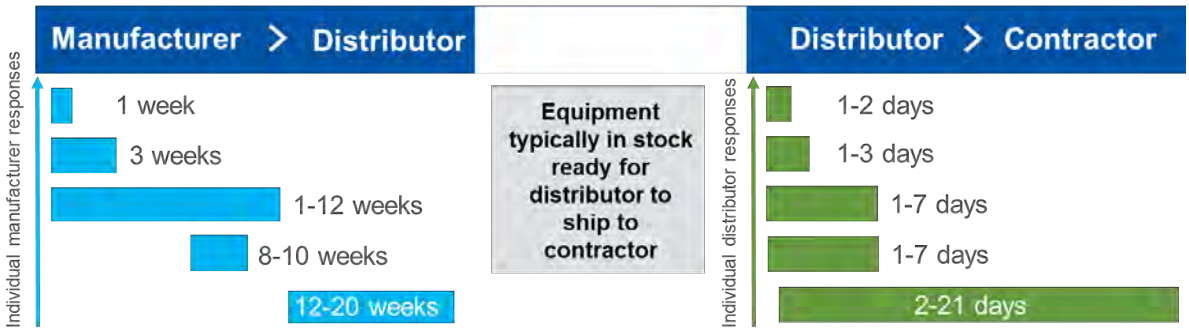
Despite manufacturing and transportation delays, distributors generally reported having stock on hand, so installation times were either not impacted or were only impacted temporarily. For the most part, distributors had learned how to manage around these constraints by being proactive and front-loading inventory. With enough inventory in stock, they can prevent delivery delays from impacting installation timelines:

- "With COVID-19, a lot of the supply chains have been broken. We were very responsive and proactive this year by buying up huge amounts of inventory. If we were to stop purchasing equipment now (March 2021), we would have enough equipment to last through November." – Distributor
- "This whole COVID thing really threw a wrench in a lot of this, and so I think a lot of it, the success that we have seen, having a little bit of inventory in Michigan, has to be to the credit of the distributor being proactive." – Manufacturer

When distributors have stock on hand, they reported that they typically deliver equipment to the contractor within one week, as shown in Figure 2. For a custom system or for equipment not in stock, the delivery timeline can stretch to three weeks or more, and one distributor had seen delays reach as long as six to eight weeks at points earlier in the pandemic, saying, "Much like everything else in the world, COVID really wreaked some havoc on manufacturing, so you know there were some times when it was six to eight weeks, but thankfully with good planning, we had enough stock that we really didn't have to deal too much with it [delays]." One distributor stated that custom equipment requires roughly 30 days to get to the contractor. Note that with the exception of this one distributor, timelines for custom equipment were not discussed in the interviews. It is possible that timelines for custom equipment could be different.

Notably, manufacturers and distributors have not observed any issues with the supply chain or with installation timelines that are unique to CCHPs or to Michigan.

Figure 2. Equipment Delivery Timelines Reported by Distributors



Note: The range in times for equipment to be delivered from the manufacturer to the distributor is due to differences between oversees versus land shipping and rush versus standard orders. One distributor also noted that COVID-19 led to six- to eight-week delays in equipment getting from the distributor to the contractor.

Cold-Climate Heat Pump Cost Differences across States

Most interviewed distributors and manufacturers did **not** report CCHP cost differences between Michigan and other states. One exception was a distributor who reported that installation costs in Michigan are higher compared to the Northeast. The distributor linked this difference to lower familiarity among installers in Michigan and said they expect costs to go down as installers become more familiar with the technology.

Within Michigan, interviewees observed differences in cost based on location in the state, with labor costs in urban areas being higher than costs in more rural areas. As one distributor stated, "Michigan prices are pretty average compared to Ohio [prices]. If you're in a more rural area, installation prices tend to go down, and if you're in a bigger, more metropolitan area then prices tend to go up."

One manufacturer also pointed out cost differences depending on whether contractors are union or non-union: "We go from $85 an hour that a contractor will charge a consumer to $140, especially if they are [in] a union. Or [when] you get into the Motor City, they seem to think they can charge a lot more."

Four of the five distributors reported increased CCHP costs over the last six months, and two interviewees noted that the cost of materials is rising—particularly for sheet metal, steel, and copper—which could lead to further cost increases down the road. As one distributor said, "[Internal costs] are going through the roof, [and] manufacturers can't eat it all."

Contractor Engagement

All five of the interviewed distributors shared the perception that there are still contractors in Michigan who do not have a full understanding of CCHPs and need to become more familiar with the technology and benefits. All five distributors also reported offering trainings to contractors to further their knowledge of CCHPs, including installation and service trainings as well as sales-oriented trainings: "We do training at every level possible, from technical service/installation to sales, and we have even offered business training."

Reports of attendance at trainings varied, with three who said their trainings were well-attended, one who said there was a mix of well-attended and less well-attended trainings, and another who said they were not well-attended, which they attributed to a lack of awareness of CCHP technology. One distributor also reported that, in their experience, one-on-one trainings work better than trainings offered in a group setting. Many training offerings have been moved to virtual platforms like Zoom due to the pandemic, which two distributors noted has been more challenging than in-person trainings.

Interviewees noted that trainings do not differ by state, e.g., they do not address specific climate, available programs, or current policies.

Barriers to Adoption

Four distributors mentioned that one barrier to CCHPs becoming more common in Michigan is that awareness of and trust in CCHP technology is not yet widespread among contractors in the state.

Instead, they reported that many contractors continue to hold an outdated perception that heat pumps are not a viable option in cold climates:

- "A lot of the contractors, especially a lot of the old timers... They don't see heat pumps as a viable option in Michigan. We hear that so many times." – Distributor
- "As technology continues to get better and heat pumps can operate at lower temperatures, you're always going to have an old service tech or installer that absolutely does not believe in the new technology." – Distributor
- "A lot of contractors are not as informed as they could be." – Distributor

Other barriers mentioned include concerns about up-front and long-term costs and, relatedly, the lack of incentives (since current policies in Michigan do not allow utilities to incentivize customers to switch from natural gas heat to electric heat).

Interviewees reported that demand for CCHPs is higher in other states than in Michigan. One attributed this lower demand in Michigan to the lack of widespread understanding among contractors and customers that heat pumps can be effective in cold climates. Others discussed the trade-offs in switching from different fuel sources. One distributor pointed out that natural gas is cheaper in Michigan than in other states, making CCHPs less cost-effective, and therefore less appealing, for those who currently use natural gas heating.[13] For those who use more expensive propane or fuel oil systems, however, distributors felt switching to a heat pump *would* be more cost-effective: "All-electric heat is a no-brainer. If they have propane or fuel oil, [heat pumps] make sense. With a natural gas system, it is a tougher sell."

Overcoming Barriers

Although interviewees reported that demand for heat pumps is lower in Michigan than elsewhere, they have also observed that demand in the state is increasing. Two distributors reported seeing major growth in CCHP adoption in recent years: one reported that their 2021 quarter 1 CCHP sales were greater than CCHP sales in the previous two years combined, and another reported having record demand in 2020, with sales doubling from 2019.

> "Ductless mini-splits are a huge, growing market, [with] the largest growth potential of any [technology], and everyone is saying the same thing."
>
> - Distributor

While there are still awareness and education gaps, interviewees reported that contractors and customers are becoming increasingly familiar as CCHPs have become more technically viable. As mentioned above, CCHPs are also increasingly *economically* viable in rural areas where there is a reliance on propane and oil heat.

[13] The proportion of households in Michigan with natural gas heating (82%) is higher than in most other states (Consumers Energy. 2018 Residential Saturation Study. Not available online).

The two biggest tools that interviewees noted as key to increasing CCHP adoption are incentives and increasing contractor and customer education. Several distributors emphasized that incentives and rebates are highly appealing to customers, making them an important tool for increasing adoption:

- "Customers would be willing to switch with an incentive." – Distributor
- "Incentives help to drive adoption." – Distributor

> "[It's] all about making the contractors aware of the benefits." – Distributor

Contractor education is also seen as a need, both to increase awareness of the viability of CCHPs in the state and to improve contractors' understanding of the benefits and cost-effectiveness of CCHPs.

Increasing Adoption

Distributers and manufacturers mentioned that Consumers Energy has been actively working to increase CCHP adoption, and they see the role of utilities as critical in helping this new technology gain a foothold.

> "The role of the utility is very important because they are the ones that can accelerate the [adoption of CCHP] technology." – Distributor

Distributers and manufacturers suggested that Consumers Energy can further encourage adoption in three ways: through education and training, by providing sales tools, and by offering incentives. Additional education and marketing directed at customers is needed to increase their awareness of the benefits of CCHPs.

> "There is a lack of information about the difference between costs for gas and electric." – Distributor

Similarly, interviewees suggested providing in-person trainings to contractors about rebates and the benefits of CCHP technology, including targeted trainings for technicians who may need more help to transition to a new technology. Three interviewees also said it would be useful to have a calculator tool that helps contractors easily demonstrate cost savings for switching to CCHP technology.

Interviewees also suggested that higher incentives would be instrumental in increasing CCHP adoption, and primarily felt that incentives should be offered via a midstream strategy. While one interviewee said rebates should be directed to contractors, all the other interviewees suggested that rebates should be directed to distributors, with one saying it would be helpful to have automatic incentives that minimize paperwork. One interviewee also suggested that incentives should be provided for CCHPs that have equivalent seasonal energy efficiency ratio (SEER) ratings as incentivized air conditioners.

> "Utility rebates really help. In some cases, the rebate has been able to cover the difference [between an AC and a heat pump]." – Distributor

Residential Market Rate Initiative Findings

In November 2021, the Evaluation team sent a survey invitation to 29 Residential Market Rate pilot participants who had valid emails. The email survey invitation included a $15 incentive for taking the survey. Nine of the 29 participants completed the survey, for a 31% response rate; with such a small sample size, the results should be interpreted with caution and only viewed as directional indications (not intended to be analyzed with statistical confidence).

In addition to the participant survey, the Evaluation team conducted an engineering analysis to determine market rate CCHP participants' energy and utility bill cost savings. The Evaluation team used data collected from the Consumers Energy initiative team and calculations that can be found in the *Michigan Energy Measures Database* (MEMD).[14]

This chapter first provides details of Residential Market Rate pilot participants, then covers the engineering analysis findings.

Market Rate Participant Survey

The Evaluation team designed the participant survey to address several key objectives:

- Assess awareness of and motivation for installing heat pumps
- Assess the participant installation experience
- Document perceptions of heat pumps, energy or cost savings, and comfort levels
- Document participant usage behavior
- Assess satisfaction with the offering and with Consumers Energy

Awareness and Motivation

All nine respondents confirmed that they received a rebate for their heat pump and that they were present when the heat pump was installed. While most (eight of nine) were familiar with heat pumps before deciding to purchase one for their home, few (three of nine) were aware that Consumers Energy provided heat pump rebates (Figure 3). Respondents first learned about Consumers Energy's heat pump rebate primarily through their contractor (four of nine) or from a Consumers Energy email (two of nine). About half (five of nine) said a contractor had recommended a heat pump before they learned about and applied for the Consumers Energy heat pump rebate.

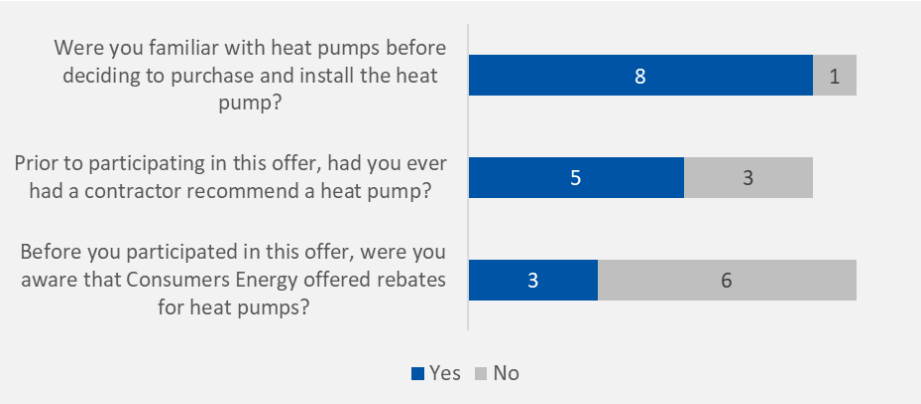
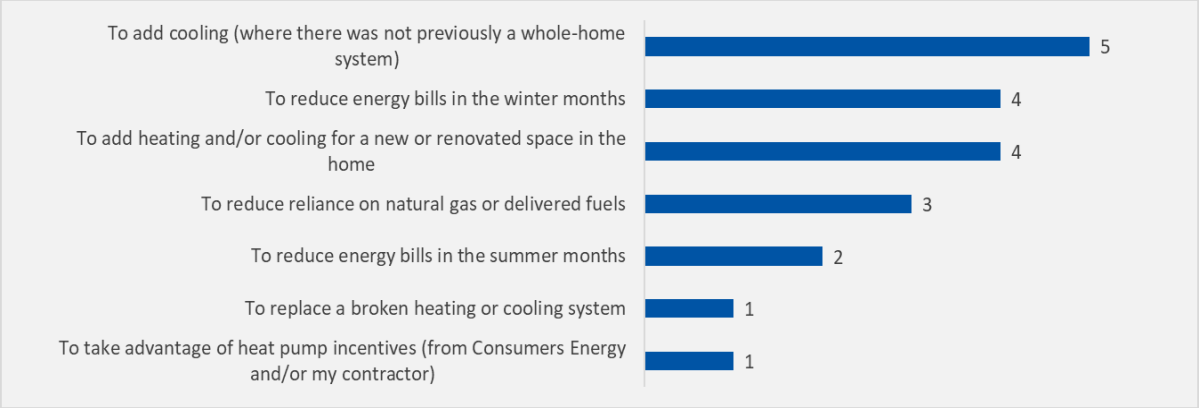
Figure 3. Heat Pump Awareness



Source: Heat Pump Market Rate Customer Survey Questions B3, B4, and B5 (n=9).

Although respondents could indicate several different motivations for installing a heat pump, responses were most frequently associated with space cooling needs and saving money on energy bills. Most respondents (n=5) installed a heat pump to add cooling where there was not previously a whole-home space cooling system. Four respondents each wanted to reduce energy bills in winter months and wanted to add space heating or cooling for a new or renovated space. Three respondents wanted to reduce their reliance on natural gas or delivered fuels (Figure 4).

Figure 4. Motivations for Installing a Heat Pump



Source: Heat Pump Market Rate Customer Survey Question B7. "What were the main reason(s) you decided to install a heat pump in your home?" (n=9; multiple responses accepted)

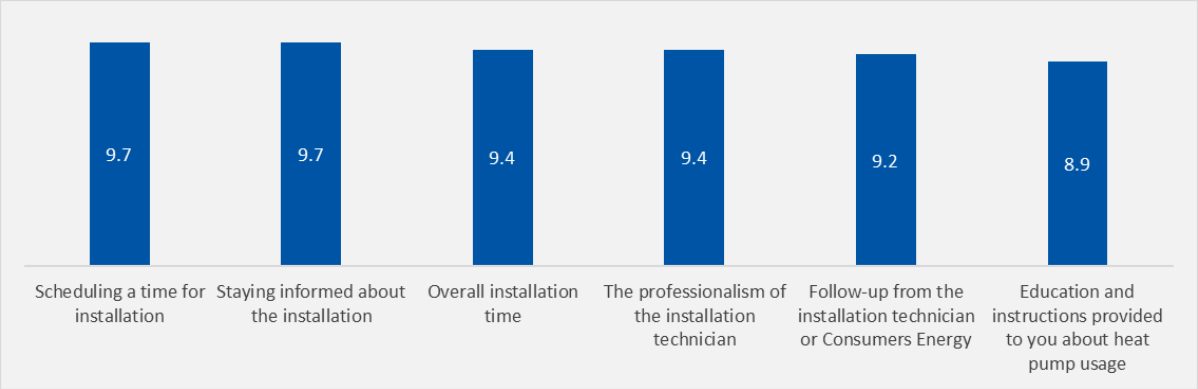
When asked to rate the importance of several factors in their decision to install a heat pump, respondents rated energy savings (over the previous heating/cooling system) as the most important (with a mean rating of 9.1 on a 10-point scale, where 1 meant *not at all important* and 10 meant *extremely important*). The contractor's recommendation received a mean rating of 8.0, and the rebate amount received the lowest rating of all decision factors, at 7.6.

Installation Experience

Respondents were engaged with the installation experience: all of them were present during the installation. Most (eight of nine) received instructions on how to set up and control the heating and cooling schedule on their heat pump at the time of installation. Only one respondent said the installation contractor set up a heating and cooling schedule for them but said they had adjusted that original schedule to address changes in their home's conditioning needs.

Respondents provided very high ratings for aspects of the installation experience, with scheduling and staying informed about the installation receiving the highest mean ratings (of 9.7 on a 10-point scale, where 1 meant *unacceptable* and 10 meant *outstanding*; see Figure 5).

Figure 5. Installation Experience Ratings



Source: Heat Pump Market Rate Customer Survey Question D2. "How would you rate each of the following installation experiences with the heat pump offering?" (n=9)

The lowest rating (of 5) was provided by one respondent for the "education and instructions provided about heat pump usage," but that person did not answer the follow-up question about why they gave that rating.

Heat Pump Perceptions

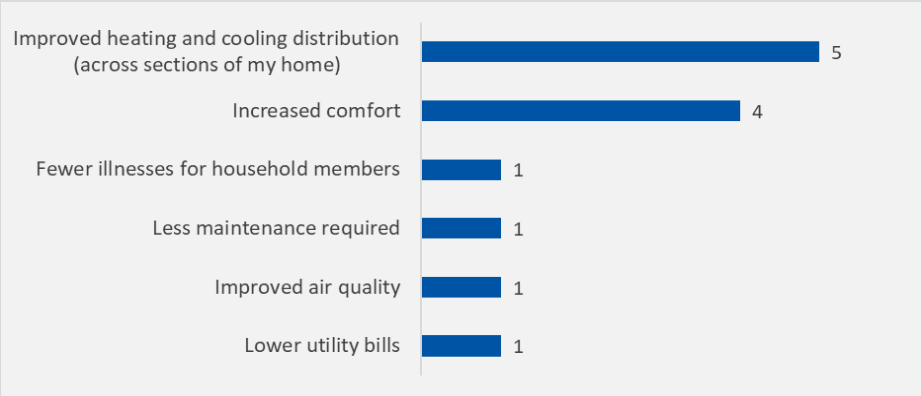
Most respondents (seven of nine) said their home is more comfortable after installing the heat pump, while the other two respondents said their home is equally as comfortable as before the heat pump was installed. One respondent also volunteered that their home air quality was vastly improved, which was also a primary reason they installed the heat pump.

Five respondents rated the comfort level provided by the heat pump in winter months, providing a mean rating of 8.6 on a 10-point scale, where 1 meant *unacceptable* and 10 meant *outstanding*. None indicated any concerns with the heat pump's ability to heat to a preferred comfort level. Comfort ratings for summer months were higher, at an average of 9.1 with ratings from all nine respondents.

Overall, perceptions were mixed about whether respondents had seen savings on their energy bill since the heat pump was installed. Four respondents said it was too soon to tell if their energy bill was affected, while two said they had a lower-than-expected energy bill and two said they had not seen a lower-than-expected energy bill.

In addition to energy savings, respondents reported several additional benefits that they value in their heat pump. With several response options provided, the most frequent benefit selected (by five respondents) was improved heating and cooling distribution across sections of the home (Figure 6). This was followed by four respondents who said the heat pump provided increased comfort. One respondent each indicated having lower utility bills, less required maintenance, improved air quality, and fewer illnesses for household members.

Figure 6. Heat Pump Benefits

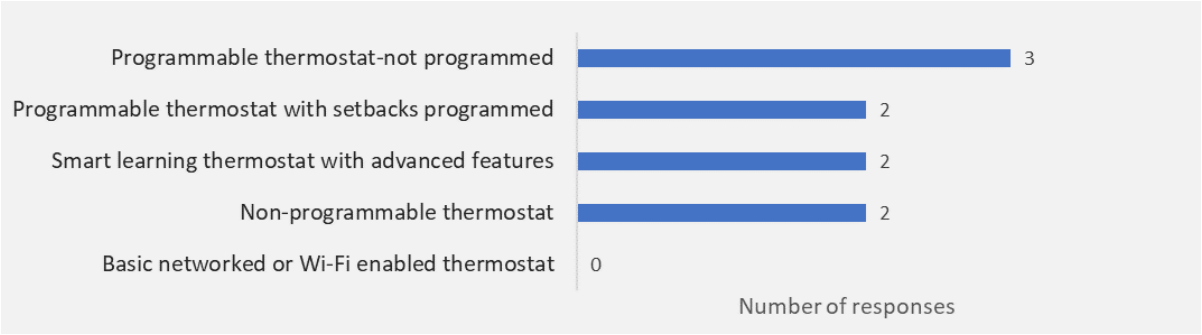


Source: Heat Pump Market Rate Customer Survey Question D13. "In addition to energy savings, if any, are there any other benefits you have experienced or observed from the installation of a heat pump?" (n=9; multiple responses accepted)

Thermostat Usage Behavior and Experience

While five of nine respondents had programmable thermostats, only two of those five used programmed temperature setbacks to control their heat pump temperature settings. Two respondents had smart learning thermostats with occupancy sensing and schedule learning capabilities, and two others had non-programmable thermostats with manual-only controls (Figure 7).

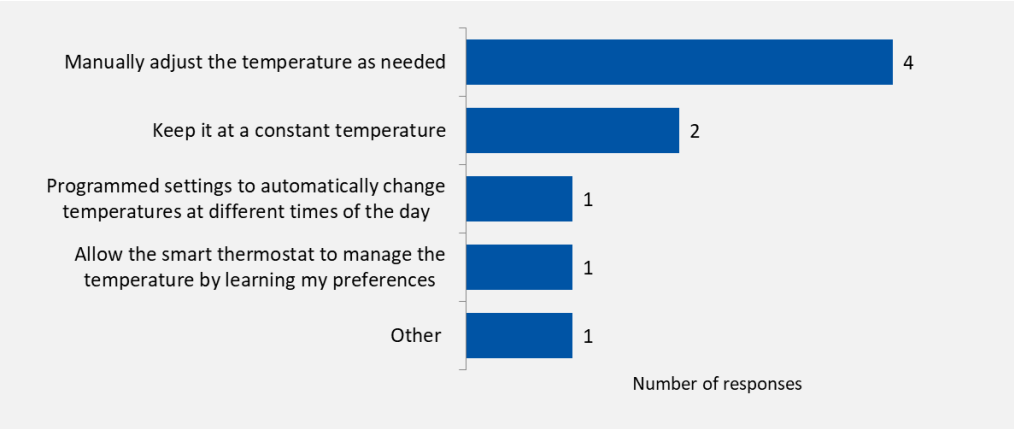
Figure 7. Respondent Thermostat Types



Source: Heat Pump Market Rate Customer Survey Question C1. "What type of thermostat do you have in your home?" (n=9)

Respondents, either singularly or with other household members, monitor and adjust the home heating and cooling settings. Despite most having programming capability through their thermostats, four of nine said they adjust the temperature manually (Figure 8).

Figure 8. Thermostat Management



Source: Heat Pump Market Rate Customer Survey Question C3. "How did your household most frequently manage your thermostat to control the temperature in your home this summer?" (n=9)

Satisfaction with the Offering and with Consumers Energy

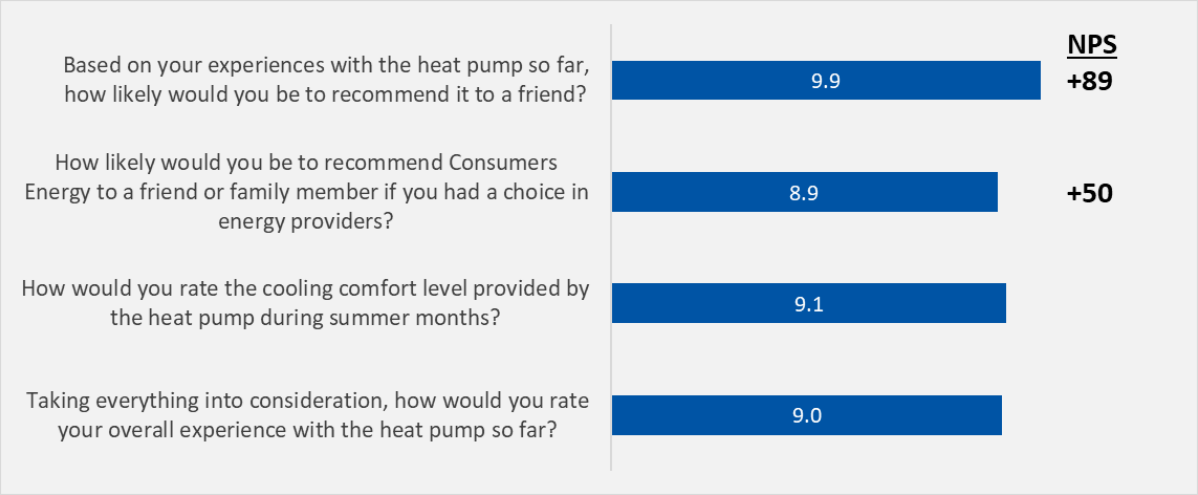
Overall, respondents were highly satisfied with the heat pump (giving a mean rating of 9.0 on a 10-point scale, where 1 meant *unacceptable* and 10 meant *outstanding*), with all nine respondents giving a rating of 8 or higher for their overall experience with the heat pump.

Another key measure of customer satisfaction is the percentage of customers who are highly willing to recommend a product, service, or company after subtracting the percentage of customers who are highly unlikely to recommend that same product, service, or company. The net percentage of those willing to promote the product is the net promoter score (NPS), expressed as an absolute number between -100 and +100 that represents the difference between the percentage of promoters (respondents giving a rating of 9 or 10) and the percentage of detractors (respondents giving a rating of 1 to 6). The Evaluation team calculated a NPS for the two likelihood to recommend questions (likelihood to recommend the initiative and likelihood to recommend Consumers Energy).

Based on their experiences, respondents were highly likely to recommend the heat pump to a friend. As shown in Figure 9, nearly all respondents (eight of nine) gave a rating of 9 or higher (with a mean of 9.9), with three indicating that they had already recommended the heat pump rebate to a friend. The resulting NPS for the heat pump is +89.

Five of eight respondents (63%) provided a rating of 9 or 10 for their likelihood to recommend Consumers Energy to a friend. Only one respondent rated their likelihood to recommend as a 5. The resulting NPS for Consumers Energy is +50, with a mean rating of 8.9.

Figure 9. Market Rate Heat Pump Participant Satisfaction



Source: Heat Pump Market Rate Customer Survey Questions D10, B1, D7, and D9. All questions used a 10-point rating scale, where 1 meant *extremely unlikely* and 10 meant *extremely likely*, with an "already did" response option as a 10 rating (n=9).

The NPS for recommending the heat pump is considered very high and compares favorably to other efficiency programs with similar measures. For example, HVAC participants provided a program NPS of +76 and a Consumers Energy NPS of +63 in 2021. Again, caution is recommended in interpreting numeric results due to the small sample size with the Residential Market Rate pilot response population.

When asked to elaborate on their rating for recommending Consumers Energy, respondents gave positive comments:

- "Consumers Energy has been a good power company. They keep us informed on rebates, power outages, etc. During power outages they are great at restoring power quickly and keeping us informed on time frames. The rebate for heat pumps was one of the reasons we decided to try a heat pump. Our power bill has gone up, but we are using our heat pump a fair amount. It is still a better option than the window air conditioner that we had before."
- "It's been a great company. I grew up in a Consumers [Energy] home and have had one [a heat pump] my entire adult life."
- "High marks for programs and communication."
- "Very happy with service and energy offers."
- "[I] like that Consumers [Energy] is trying to help on heating costs that are going up every year."
- "We don't really have much choice, but I think that Consumers Energy does a good job providing (mostly) reliable electric service (which is all you [they] provide to my area)."

Two respondents said they do not have a choice in energy company, so they do not have a point of comparison, and one commented on high rates.

The only improvement suggestion respondents provided did not directly pertain to the heat pump initiative: "Allow me to change the energy conservation program I want more than once a year. We would like to 'follow the rules' imposed during the summer year-round but cannot change because we cancelled the program we had been on (Consumers [Energy] could limit our AC during peak periods) because our contractor did not want Consumers [Energy] to be able to change our now Wi-Fi–capable system (the old one was not [Wi-Fi]) in May/early June. We did not find out about the option we'd like until later in the summer but were not allowed to use it."

Impact Analysis

The Evaluation team conducted an engineering analysis of the impacts from the Residential Market Rate pilot and relied on MEMD assumptions and information we had collected from customers such as home vintage, presence of central cooling, installed system coefficient of performance (COP)[15] at 5°F, rated heating seasonal performance factor (HSPF) and SEER, tonnage, and other data. The Evaluation team relied on the MEMD weighting tool, which generates a single measure output based on home vintage, climate zone, sizing, and efficiency levels. Since the MEMD weighting tool does not allow for varying the baseline equipment type or system efficiency, the Evaluation team used MEMD building simulation output data to develop site-specific consumption values. MEMD staff provided underlying MEMD 2019 weighting tool building simulation results for ASHPs in single-family buildings.[16] This section summarizes key findings from the engineering analysis.

There were 42 Residential Market Rate pilot CCHPs installed in homes with electric and propane heating, making up the largest percentage of pre-installation heating fuels (Table 6). Approximately half of the CCHPs were installed in homes built before 1979 (n=25) and most of the other half were installed in homes built between 1980 and 2004 (n=23). The remaining CCHPs were installed in homes built between 2005 and present day (n=3).

Table 6. Home Construction Vintage Distribution by Pre-Installation Heating Fuels

Pre-Installation Heating Fuel	1979 or older	1980 to 2004	2005 to Present	Total
Electricity	10	6	0	**16**
Propane	9	15	2	**26**
Fuel Oil	3	1	0	**4**
Natural Gas	3	1	1	**5**
Totals	**25**	**23**	**3**	**51**

[15] Coefficient of performance is simply the ratio of power (kW) in heating (or cooling) Btus generated by the CCHP, and the power (kW) that is supplied to the compressor. The higher the COP, the greater the heating energy generated for each kilowatt consumed by the CCHP.

[16] The MEMD 2021 building simulations for this measure have not been updated since 2019 and therefore reflect the latest building simulation results.

Table 7 shows the average Residential Market Rate pilot participant' annual energy and utility bill savings by pre-installation heating fuel type. Customers heating with delivered fuels (propane and oil) realized the highest heating energy savings, while customers heating with electricity prior to installation of the CCHP had the highest utility bill savings.

Table 7. Average Market Rate Cold-Climate Heat Pump Energy and Fuel Cost Savings per CCHP

Pre-Installation Heating Fuel	Number of Installed Units	Average Savings per CCHP		Average Annual Utility Bill Savings per CCHP
		Heating (MMBtu) [a]	Cooling (kWh) [b]	
Electricity	16	35	-108	$1,680
Propane	26	68	-27	$1,223
Fuel Oil	4	70	-46	$910
Natural Gas	5	54	-228	-$451

[a] Due to the different heating fuel types, savings are represented in MMBtu to allow for better comparisons.

[b] Negative savings mean that electric consumption increased rather than decreased.

The five homes that heated with natural gas will likely see an increase in their utility bill of $451 per year on average due to the relative costs of electricity and natural gas at the time of the analysis, as well as the fact that four of five homes did not have existing central AC (which will likely increase their electric usage in the summer).

As shown below in Table 8, only 22 of the 51 participants had central AC prior to the CCHP installation. For homes without central cooling, the Evaluation team assumed a portion of the homes use room or window AC units to provide some cooling. Due to the low number of homes without conditioned cooling, electric consumption increased, on average, across all baseline heating fuel types. However, homes that did have central cooling before the CCHP installation saw savings from $20 to $96.

Table 8. Central Cooling Presence Distribution and Associated Cooling Savings

Pre-Installation Heating Fuel	Central Cooling?	Number of Installed CCHPs	Annual Cooling Electric Savings per CCHP
Electricity	Yes	5	$33
	No	11	-$37
Propane	Yes	15	$57
	No	11	-$69
Fuel Oil	Yes	1	$96
	No	3	-$35
Natural Gas	Yes	1	$20
	No	4	-$50

Table 9 shows the total Residential Market Rate pilot annual energy and utility bill savings by pre-installation heating fuel type for all CCHPs.

CADMUS

Table 9. Total Market Rate Heat Pump Energy and Fuel Cost Savings

Pre-Installation Heating Fuel	Count of Installed CCHP Units	Savings		Annual Fuel Costs [b]		Pre-Installation Central Cooling Saturation [c]
		Heating (MMBtu) [a]	Cooling (kWh)	Heating	Cooling	
Electricity	16	565	-1,729	$27,124	-$247	31%
Propane	26	1,774	-704	$31,701	$85	58%
Fuel Oil	4	279	-183	$3,652	-$10	25%
Natural Gas	5	270	-1,142	-$2,072	-$182	20%

[a] Due to the different heating fuel types, savings are represented in MMBtu to allow for better comparisons.

[b] The Evaluation team calculated annual heating and cooling costs based on rates and distributed fuel cost shown in *Appendix B*.

[c] Not every home was equipped with central cooling before the CCHP installation.

Income Qualified Multifamily Initiative Findings

There are two key groups of participants in the Income Qualified Multifamily initiative: property owners and managers (PMO) and tenants. PMOs are active participants who sign up for the initiative and are the primary contacts of the initiative. The tenants are indirect participants; they are not decision-makers, yet they directly benefit from the CCHP Initiatives' equipment and energy savings in their living units and they most frequently pay the resulting energy bills from CCHP operation. The Evaluation team sought feedback from both groups, conducting telephone interviews with PMOs and online surveys with tenants. The Evaluation team also sought to understand the Income Qualified Multifamily initiative's performance by analyzing electric energy savings impacts during the heating and cooling seasons through a statistical billing analysis of participating initiative properties.

This chapter outlines the results of PMO interviews, tenant surveys, and the statistical billing analysis.

Property Manager and Owner Interviews

The Evaluation team conducted telephone interviews with multifamily PMOs who participated in the CCHP initiative to gain insight into their experience. The Evaluation team designed the interview to address several key objectives:

- Document the participant installation experience
- Document participant usage behavior and experience
- Document awareness and perceptions of heat pumps
- Document participant decision-making around participating in the heat pump offering
- Identify marketing and outreach best practices
- Assess satisfaction with the offering and with Consumers Energy

As of Q3 2021, seven multifamily properties had participated in the Income Qualified Multifamily initiative. While the Evaluation team attempted to recruit all seven of the multifamily PMO initiative participants, we completed three phone-based in-depth interviews. Two of the multifamily PMO participants were from existing buildings (retrofit installations) and therefore had broad insights into the full initiative experience. The third interviewee was with a newly constructed property, which meant they had a more limited view on the tenant and installation experience.

Installation Experience

Overall, the multifamily PMOs had a positive early-stage initiative experience with scheduling, installation, and follow-up. Two of the three PMOs reported that COVID-19 caused some delays with the installation and equipment, but overall reported positive experiences. In one case, the PMO commented that the completion time was fast considering the number of units and installs: "We had something like 48 units, some large enough for multiple installations…so two-and-a-half months to install over 50 units was fast." The third PMO, the owner of a new construction property, noted the while installations were all completed on time, they did not have feedback on the tenant experience during installation (as installation happened before tenants occupied the units). For the other two PMOs with tenants living in

the units, the installer worked directly with management to notify the tenants of the installations and work around their schedules. According to these two PMOs, their tenants were generally satisfied with the heat pump installation.

Heat Pump Usage Behavior and Experience

The multifamily PMOs reported that prior to installation, tenants relied on inefficient electric baseboard systems and, in one case, had specifically requested new a HVAC system during a tenant meeting. One of the primary benefits for tenants is the ability to use AC as well as heating—while the heat pump replaced baseboard heat, there was no existing AC to replace outside of window units purchased by tenants. One PMO mentioned that nearly all tenants enjoyed the new heat pumps, with only a few tenants being confused about how to use the new system.

Two of the multifamily PMOs received direct feedback from their tenants regarding the heat pump usage and experience. According to one PMO, “the residents considered it a huge plus for them, because of all the extra benefits that the heat pumps provided them.” Another PMO remarked that the heat pumps provided significantly greater comfort, and improved air circulation, compared to the baseboard equipment, and went on to state, “the heating itself is just more efficient for the tenants; it seems to keep the apartments warmer.”

Awareness and Perceptions of Heat Pumps

Multifamily PMOs were generally aware of heat pumps prior to being approached by Consumers Energy about the rebate initiative, though they were not aware of Consumers Energy incentives or programs until their involvement in the initiative. One PMO previously had contractors recommend heat pumps, while another had heat pumps installed in other apartments in the Southeast United States (where heat pumps are more common). One of the PMOs had some hesitation about installing the CCHPs, as they noted, “historically, my understanding was that [heat pumps] didn’t do so well in cold climates. A green consultant and several HVAC engineers turned me on to them and then [I] became comfortable [that] they would be sufficient.”

PMOs generally did not report any perceived benefits of heat pumps prior to installation but were happy to report both energy and non-energy benefits, particularly tenant happiness and reduced maintenance and tenant comfort needs, after installation. As an added benefit, the simplicity of a single heating and cooling system was beneficial for both tenants and the PMOs: the number one benefit is providing heat, but efficient heat is the next important thing. As one PMO said, “There is always some kind of system [to heat], but it doesn’t always work. It’s always our number one concern to provide heating and cooling to the tenants.”

Decision-Making around Participating in the Heat Pump Offering

In both existing retrofit cases, the PMOs primarily decided to improve the existing HVAC systems due to energy efficiency and tenant comfort. One PMO cited a tenant meeting as a primary factor, where tenants explicitly requested an improved HVAC system. Generally, all PMOs wanted to improve tenant comfort, replace old equipment, improve electric efficiency, and lower electricity bills. The biggest barrier to switching over to heat pumps was cost: because the multifamily buildings already had existing

heating systems, it was a matter of prioritizing which are the most in need and how to fit that into the budget: "… if there is an existing heating system that is working, that's not necessarily something we can improve because it meets [the need for] having a functioning system, and it's harder and more expensive to switch out than other properties… so the biggest barrier is a matter of prioritizing it [CCHP installation] in the budget." According to the other retrofit PMO, the rebate allowed them to fit improved HVAC systems into the budget for that year. Tenant comfort, energy efficiency, and an improved system were the key motivations for PMOs.

For the new construction PMO, heat pumps were an attractive investment for their property, and the initiative made it "a slam dunk" for the project. The initiative allowed the property to meet LEED certification while also managing to keep the construction within budget. As the new construction PMO noted, "for our LEED-certified property, which was an all-electric building, and given [that] the units were smaller apartments, it was hard to find a furnace that would work well and integrate into the units and not be oversized. The heat pumps can really work well and are adapted to lower need, relative to [a] gas furnace. The simplicity of only electric, with no gas, requiring less piping, meant that construction was easier." This PMO went on to remark, "with the rebate, the heat pump was actually the cheaper option [relative to a gas furnace]."

Marketing and Outreach Best Practices

Multifamily PMOs agreed that the best way to conduct outreach about CCHPs is to directly contact contractors or developers. According to two PMOs, they primarily get their recommendations from contractors, who do not always provide information on CCHPs and higher-efficiency opportunities to the developers. One existing building PMO said, "if I had someone directly to talk to, I would bring this up to [building owners] more…I confer with architects and specialists on building recommendations, but they don't necessarily know all the tenant benefits. So, I would recommend reaching out to more developers, like myself, directly." Both PMOs recommended emails or pamphlets with the overall costs and energy savings and direct information as a convincing outreach strategy: "Anything that involves a description, some costs, energy savings…I think those are the highlights," the construction manager said.

Two of the PMOs learned about the heat pump offering through direct contact with Consumers Energy, while one learned about it from their LEED consultant. When asked what the preferred means of communicating future offerings, all three PMOs tended to prefer email, but also noted phone calls.

One interviewee (the resident manager) mentioned that his property manager was the decision-maker in the process, and that energy companies should do more to contact property managers directly, because most are not aware. "[The property manager] was different," the resident manager said, "He was always searching for rebates and things like that…both to improve the apartments for the tenants, but also because of the resource—using less energy is good for the economy, that kind of thing. But most property managers aren't searching like he was." Another PMO said, "Most people don't know enough and aren't aware [that heat pumps] can work on their own in colder climates. We have now had a full winter with new tenants and the CCHPs and received no complaints: it all went well."

Satisfaction with the Offering and with Consumers Energy

Overall, the participating PMOs were highly satisfied with their initiative experience and with Consumers Energy (Figure 10). The three PMOs provided an average rating of 9.5 on a 10-point scale (where 1 meant *unacceptable* or *extremely unlikely* and 10 meant *outstanding* or *extremely likely*) for their satisfaction with the initiative and their likelihood to recommend heat pumps to a colleague. The PMOs also rated their likelihood to recommend Consumers Energy as a 9.3 and rated their likelihood to adopt similar CCHP equipment in their other properties as a 9.0 (Figure 10).

Income Qualified Multifamily Tenant Survey

In November 2021, the Evaluation team surveyed a group of multifamily tenants who resided in units that received CCHPs as part of Consumers Energy's CCHP initiatives and 32 completed the survey

The Evaluation team designed the survey to address several key objectives:

- Document awareness of heat pumps
- Understand the participant installation experience
- Assess tenant perceptions of heat pump impacts on comfort levels and electricity bills
- Document participant usage behavior and experience
- Assess satisfaction with the offering and with Consumers Energy

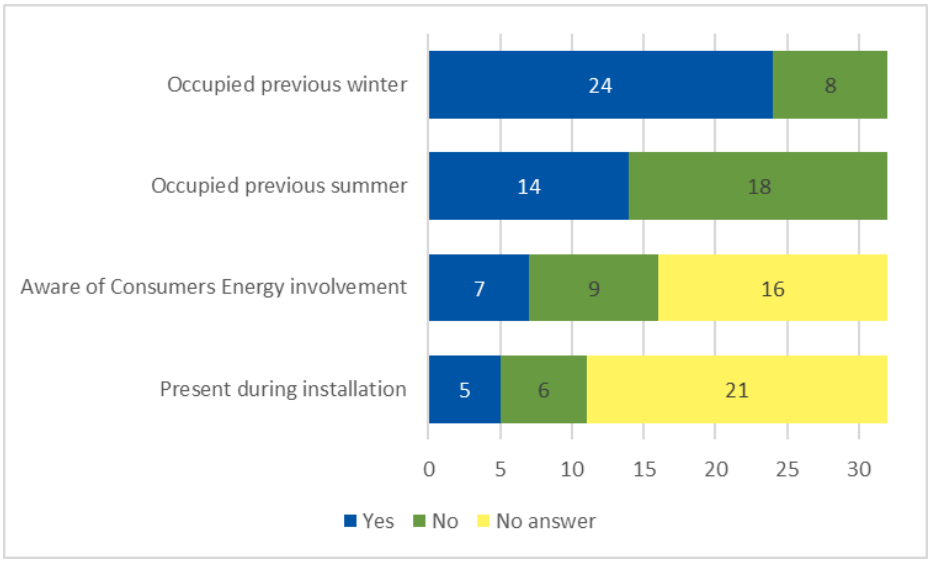
Tenant Survey Background

The multifamily tenant survey included questions about topics such as whether respondents manage the temperature of their unit, whether they pay their bills, and how long they have resided in their unit. Additionally, the team asked questions about the installation and performance of the CCHP.

All tenants who responded to the CCHP survey managed the temperature of their home personally and all said they pay their own energy bills (n=32). Most tenants (n=17) had lived in the apartment for between six months and one year while 11 others had occupied their apartment for more than one year. Additionally, three respondents said the heat pumps had not yet been completely installed and they could not provide answers about installation or post-installation.

Other participant characteristics are summarized in Figure 11. A minority of respondents were present during installation (n=5) and were aware of Consumers Energy involvement in the CCHP (n=7). Three-quarters of respondents were occupants last winter (n=24), before the installation, while one-quarter (n=8) were not present in their units to experience the old heating system, and thus could not provide comparative responses about new versus old heating system performance. Respondents' tenancy term and other factors resulted in around one-third (30%) of the responses to all questions that provided little to no insight into their experience in this initiative. Because of the low response count to many of the tenant survey questions, the results should be considered indicative but inconclusive.

Figure 11. Summary Respondent Characteristics



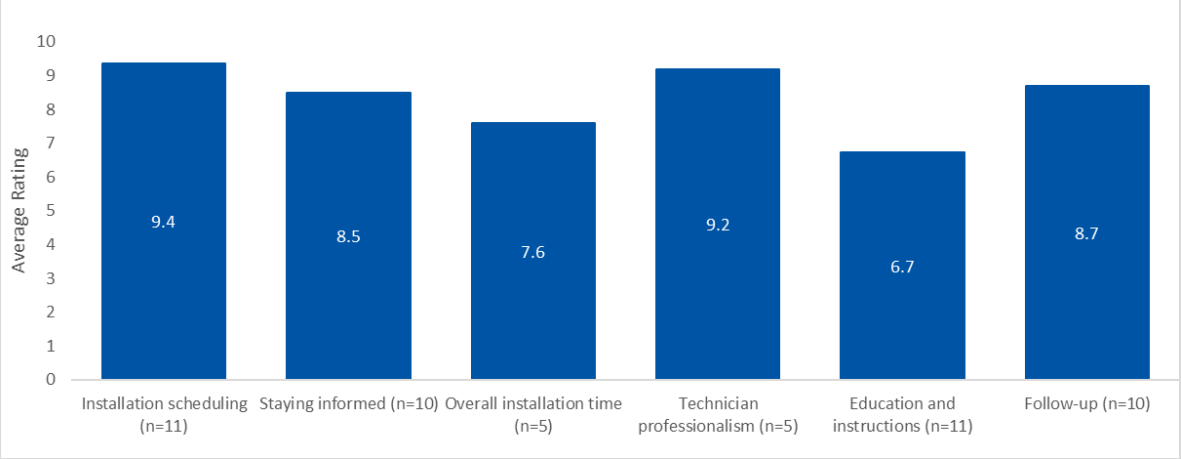
Source: Heat Pump Multifamily Tenant Survey Guide Questions C5, C8, B3, and C1. Please see *Appendix E* for specific question wording.

Participant Installation Experience

A successful equipment installation can provide tenants with a positive initiative experience; such an installation should include providing helpful information and operational details for a better managed heating and cooling experience. One-third of respondents (n=11) provided installation experience ratings. Overall, participants were largely satisfied with the installation experience, rating most installation elements above an 8 on a 10-point scale, where 1 meant *unacceptable* and 10 meant *outstanding* (Figure 12). Respondents provided the lowest average rating to the education and instructional aspects of installation, which impacted their overall satisfaction with the heat pump

offering, as well as with Consumers Energy overall (these metrics are featured further below in Figure 19).

Figure 12. Tenant Installation Satisfaction

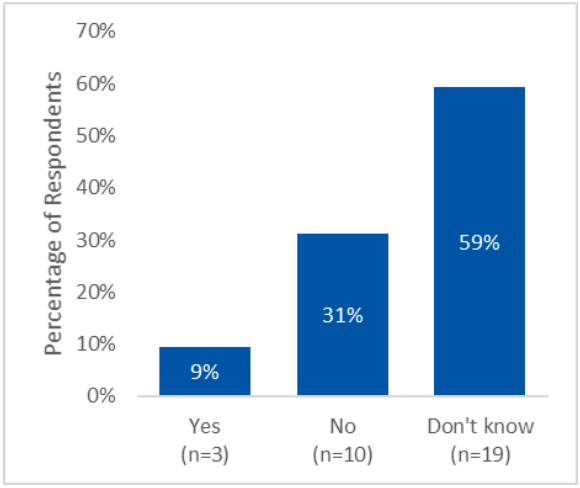


Source: Heat Pump Multifamily Tenant Survey Guide Question C2. "How would you rate each of the following installation experiences with the heat pump offering?"

Participant Usage, Behavior, and Experience

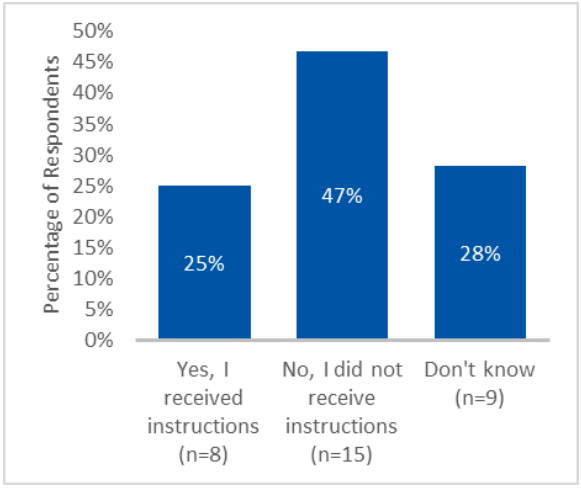
Participant usage, behavior, and experience with this offering were influenced by the installation technicians and education surrounding the CCHP equipment installation. Only three respondents could confirm with certainty that the technician set up a heating and cooling schedule for their heat pump (Figure 13). These three participants also confirmed that the heating and cooling schedule set up by the contractor is still in operation. Lack of heat pump education, materials, and follow up were common among respondents. Forty-seven percent of participants (n=15) reported not receiving documentation or instructions about the heat pumps, while 28% (n=9) did not know if they received instructions and 25% (n=8) did receive instructions (Figure 14). Other survey respondents indicated in open-ended responses that there was a lack of information relayed about the heat pumps, either from installation technicians, the PMOs, Consumers Energy, or a combination of the three.

Figure 13. Heating and Cooling Schedules



Source: Heat Pump Multifamily Tenant Survey Guide Question C16. "Did the installation technician set up your heat pump on a heating and cooling schedule?"

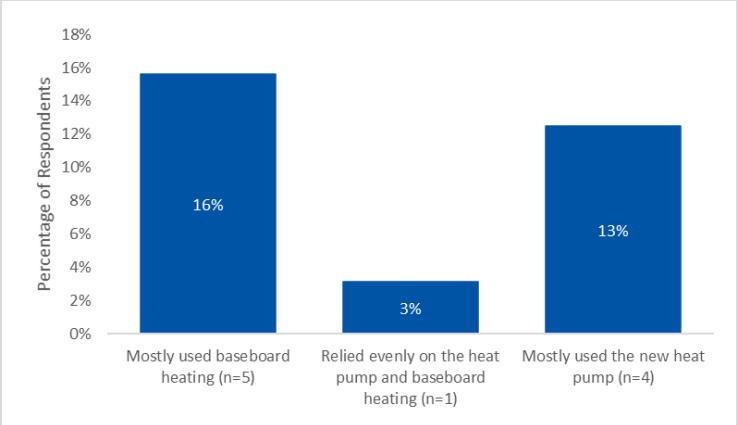
Figure 14. Instructions Provided at Installation



Source: Heat Pump Multifamily Tenant Survey Guide Question C18. "Have you been provided with instructions on how to set up and control your heating and cooling schedule on your heat pump?"

Sixteen percent (n=5) of participants reported using mostly baseboard heating after installation, while 13% (n=4) reported using mostly the newly installed heat pump and 3% (n=1) reported using both evenly. Another 68% (n=22) of participants did not know which heating source they relied on.

Figure 15. Primary Multifamily Tenant Apartment Heating Source



Source: Heat Pump Multifamily Tenant Survey Guide Question C12. "Which of the following best describes how you heated your apartment last winter?"

In open-ended responses, some tenants were unhappy with the lack of information:

- "After the installation, there was not follow up. Also, there are many in our complex that have no idea on how to set up the mobile app."
- "Manager of my complex did not [educate] me on how to use all the features. Also, when and who changes the filters, if any."

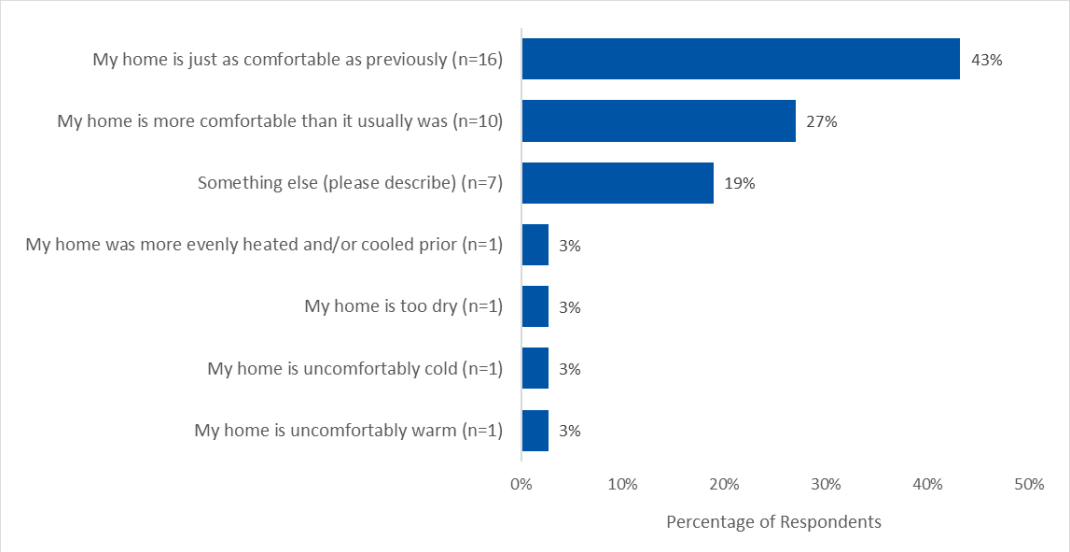
Awareness and Perceptions of Heat Pumps

Most participants (68%; n=21) reported a complete lack of knowledge regarding heat pumps, even after installation. More interestingly, half were not aware that there was a heat pump installed in their apartment, despite having occupied the unit at the time of installation. Of the half that were aware of the heat pump installation, 56% (n=9) did not know Consumers Energy was involved in the project. In an open-ended response, one participant was surprised: "I didn't know anything about how to run the heat pump or maintenance needed. We weren't told anything. We didn't even know Consumers [Energy] funded it."

Perceptions of Heat Pump Impact on Comfort Levels and Electricity Bills

As noted above, PMOs indicated tenant comfort was a key factor in the decision to participate in the heat pump initiative—some tenants supported this perception. Post-installation, although 43% of tenants reported their homes to be as comfortable as before, one-quarter of tenant survey respondents reported increased comfort (27%). Specifically, few tenants reported issues with temperature or humidity regulation, as shown in Figure 16.

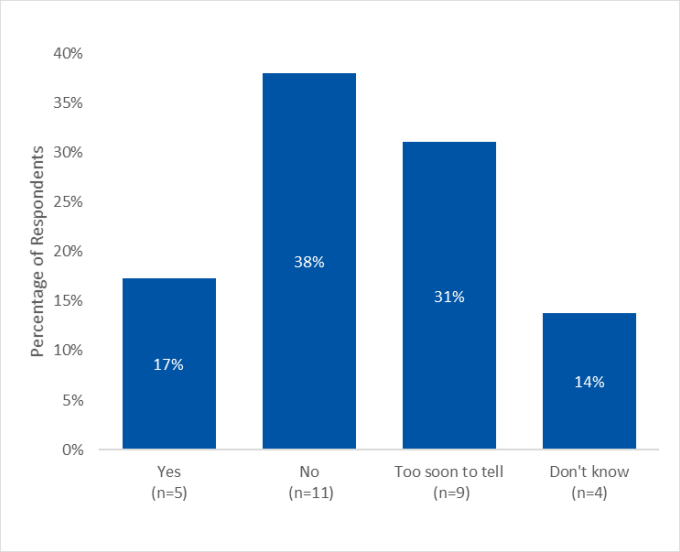
Figure 16. Heat Pumps and Home Comfort



Source: Heat Pump Multifamily Tenant Survey Guide Question C11. "In general, how did the heat pump affect your home comfort?"

Over twice as many income-qualified multifmaily respondents believed they did not experience any savings on their energy bills as those who believed they did experience savings: 38% of respondents (n=11) reported no savings on their energy bills, compared to 17% (n=5) who reported savings (Figure 17).

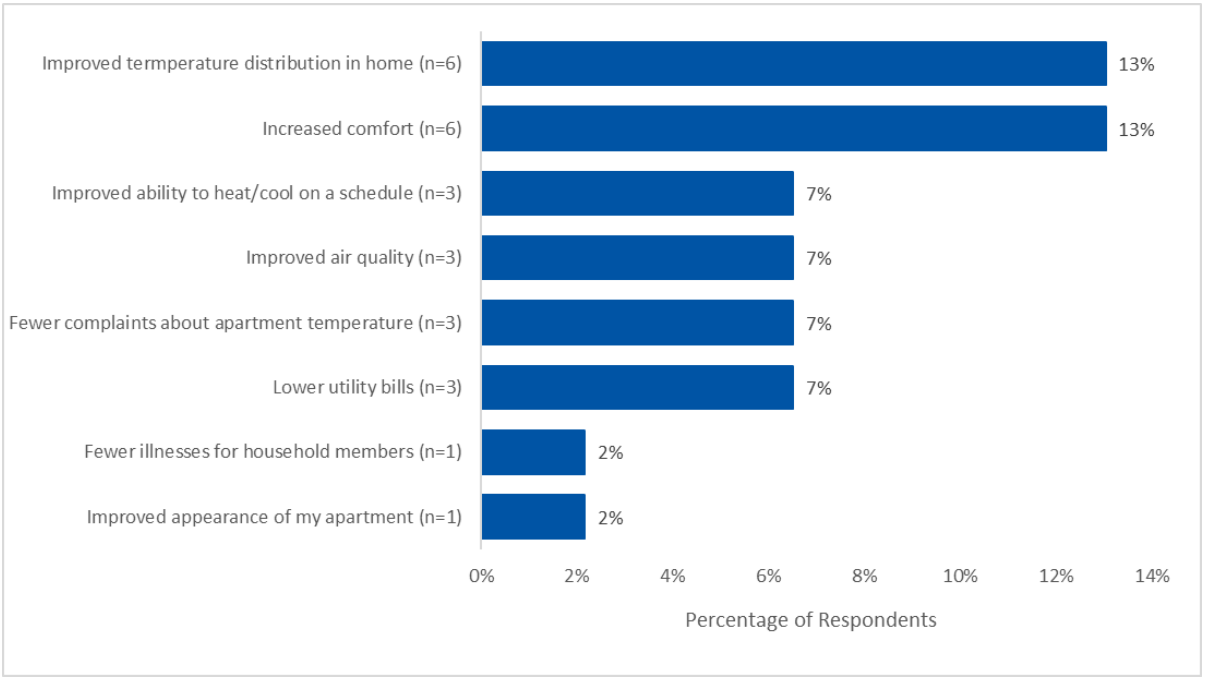
Figure 17. Multifamily Tenant Energy Bill Savings



Source: Heat Pump Multifamily Tenant Survey Guide Question D2. "Have you seen a lower-than-expected energy bill?"

Even with few respondents believing the CCHPs resulted in bill savings, a high number reported non-energy saving benefits of the CCHPs, primarily related to temperature distribution and comfort (Figure 18).

Figure 18. Non-Energy Benefits



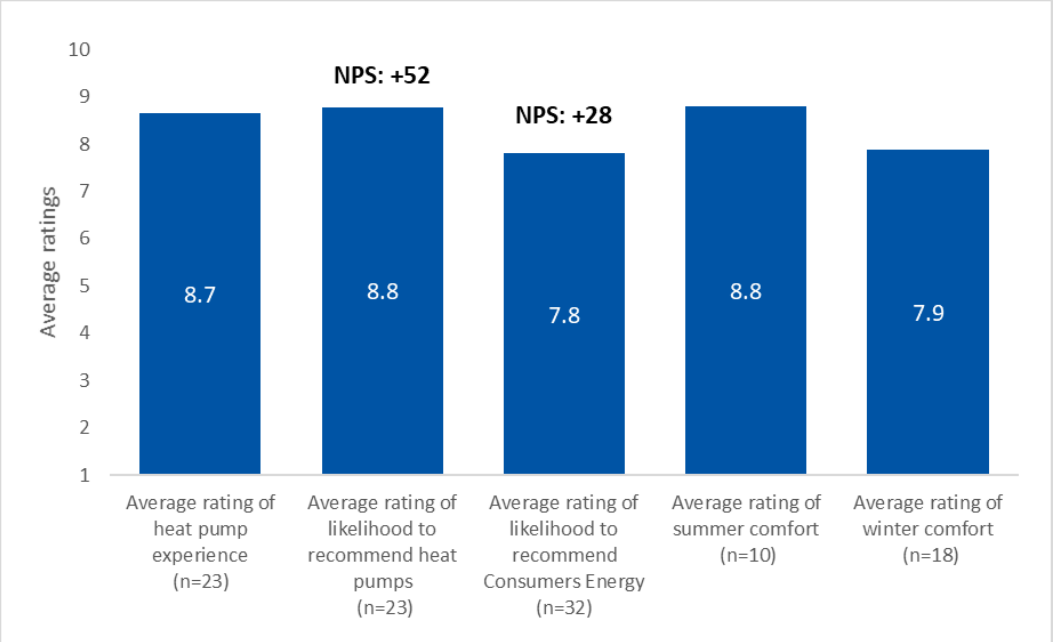
Source: Heat Pump Multifamily Tenant Survey Guide Question D3. "In addition to energy savings, if any, are there other benefits that you have experienced or observed from the installation of heat pumps?"

Satisfaction with the Offering and with Consumers Energy

Income-qualified multifamily tenants were satisfied with the CCHP experience, and generally felt that the heat pumps provided improved winter heating and summer cooling comfort. CCHP multifamily tenant participants reported an average rating of 8.7 regarding their overall experience with the heat pump, an average of 8.8 rating on likelihood to recommend a heat pump to a friend, and an average of 7.8 rating on likelihood to recommend Consumers Energy, all on a 10-point scale where 1 meant *unacceptable* or *extremely unlikely* and 10 meant *outstanding* or *extremely likely* (Figure 19). Respondents also reported an average rating of 8.8 regarding summer comfort and 7.9 regarding winter comfort.

Another key measure of customer satisfaction is the percentage of customers who are highly likely to recommend a product, service, or company after subtracting the percentage of customers who are highly unlikely to recommend that same product, service, or company. The net percentage of those willing to promote the product is the net promoter score (NPS), expressed as an absolute number between -100 and +100 that represents the difference between the percentage of promoters (respondents giving a rating of 9 or 10) and the percentage of detractors (respondents giving a rating of 1 to 6). The Cadmus team calculated a NPS for the two likelihood to recommend questions (likelihood to recommend the CCHPs and likelihood to recommend Consumers Energy – see Figure 19 below).

Figure 19. Satisfaction with Cold-Climate Heat Pump Experience and Comfort



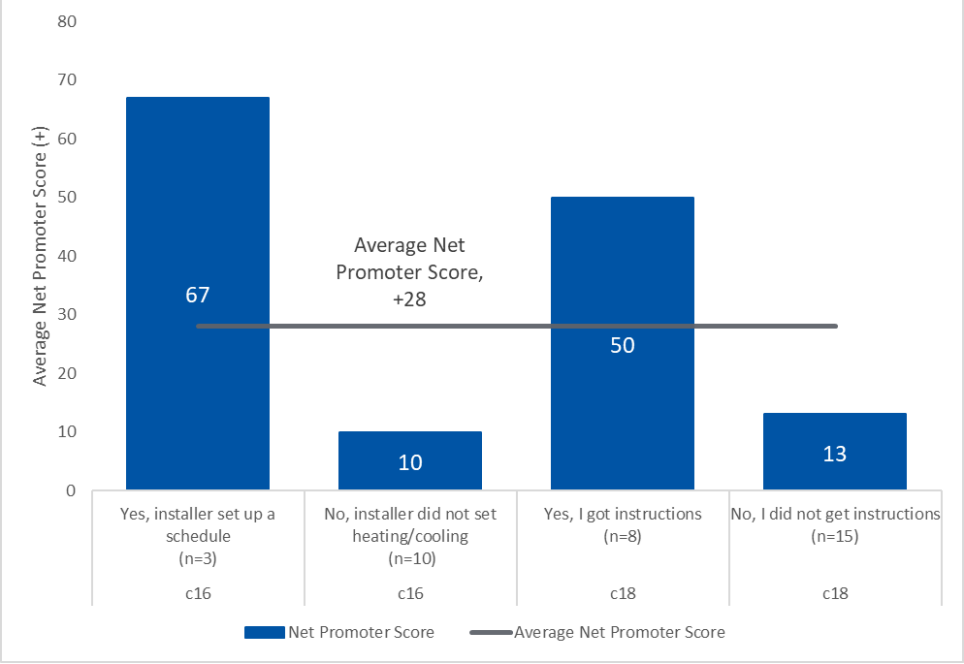
Source: Heat Pump Multifamily Tenant Survey Guide Questions E1, E2, A1, C9, and C6. Please see *Appendix E* for specific question wording.
This figure reflects combined average satisfaction ratings of heat pump experience and comfort.

The Evaluation team also calculated a NPS for the two likelihood to recommend questions (likelihood to recommend the CCHPs and likelihood to recommend Consumers Energy). As shown in Figure 19, based

on experiences with the heat pump, respondents were somewhat likely to recommend the heat pump to a friend. Though 14 respondents were promoters (providing ratings of 10) and only two were detractors, nine respondents did not provide a rating and seven were passives. The resulting NPS for the heat pump was +52. Sixteen respondents provided a 9 or 10 rating for likelihood to recommend Consumers Energy to a friend while seven provided ratings below a 7 and were classified as detractors (nine respondents were classified as passives). The resulting NPS for Consumers Energy was +28.

The Evaluation team compared the Consumers Energy NPS across different participant groups (Figure 20). Participants who provided low ratings on installation communication and instructions and provided verbatim feedback around lack of education materials and instructions were more likely to provide a lower overall Consumers Energy NPS. In fact, this cohort on average provided the lowest ratings of all participants. Additionally, participants who received instructions or had their heating and cooling schedule set by installation technicians had a higher NPS on average than both the survey average and the average of those who had no instructions or schedule set.

Figure 20. Average Consumers Energy Net Promoter Score and Installation Satisfaction



Source: Heat Pump Tenant Survey Guide Questions A1, C16, and C18. “How likely would you be to recommend Consumers Energy to a friend or family member if you had a choice in energy providers?” “Did the installation technician set up your heat pump on a heating and cooling schedule?” and “Have you been provided with instructions on how to setup and control your heating and cooling schedule on your heat pump?”

Open-ended responses regarding Consumers Energy were primarily positive in nature, though some were frustrated with Consumers Energy's service, mostly reporting high bills:

- "Great customer service and payment plans. But the cost in the winter is way higher than I think it should be."
- "My bill was all over the place last winter reaching almost $300 between two small school-aged kids who were gone most of the day and myself who unplugs everything."
- "Because I'm low income with social security income where there's no assistance help for my electric bill, the bill can be extremely expensive."

Nearly all positive responses cited great customer service and the ease of payment:

- "Service has been great for me in as long as I've been with them."
- "Good service and consistent customer service."
- "Very easy online payments and very easy outage center updates. It's also nice to have those text and email reminders about billing."

Impact Analysis

This section summarizes findings from the Evaluation team's statistical billing analysis, conducted to determine electric energy savings resulting from the Income Qualified Multifamily initiative. While the focus of the initiative and the billing analysis were on electric-heated properties (and therefore on electric impacts on heating use during the winter heating season), the Evaluation team also used the billing analysis to determine the electric energy impacts associated with summer cooling season. *Appendix B* has a detailed discussion of the methodological approach we used to determine the energy savings.

Key Findings

The Evaluation team estimated the electric energy impacts of CCHP installations separately for winter electric heating and summer cooling impacts. The Income Qualified Multifamily initiative participant electric savings results, presented in Table 10, show winter electric heating energy savings of 832 kWh, equivalent to 22.9% of baseline weather-sensitive electric heating use.

Table 10. Multifamily Income Qualified Heat Pump Electric Energy Savings

Group	Weather-Sensitive Electric Usage (kWh)		Weather-Sensitive Electric Savings		Precision at 90%
	Pre-Period	Post-Period	kWh	Percentage	
Winter heating	3,626	2,794	832	22.9%	±9%
Summer cooling	234	170	64	27.1%	±24%
Total Annual (Weather Sensitive)	3,860	2,964	896	23.2%	±8%

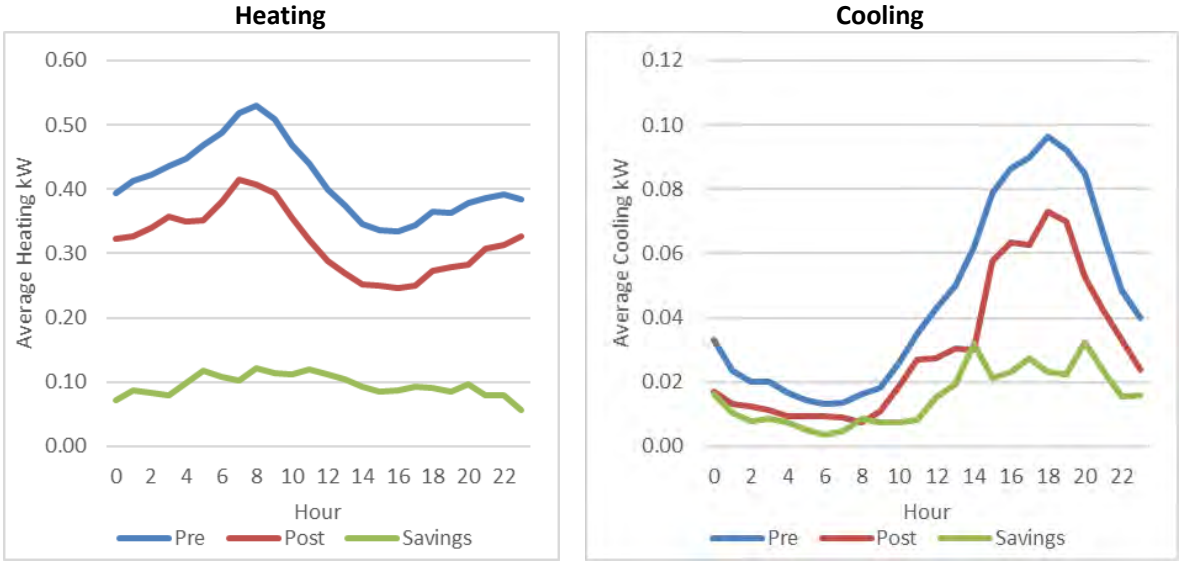
Source: Evaluation team billing analysis.

The billing analysis estimate of 64 kWh savings per unit during the summer cooling season reflected a similar percentage reduction in weather-sensitive electric usage attributable to the CCHPs (at 27%

relative to the 23% for winter heating). The heating electric analysis produced savings estimates within the ±10% precision threshold at a 90% confidence interval and therefore the results were statistically significant. Given the lower cooling load and therefore more variable signal, the cooling savings were outside the ±10% precision target. Overall, the Income Qualified Multifamily initiative resulted in a statistically significant annual reduction of 896 kWh for each participant tenant unit, representing 23.2% of the annual weather-sensitive electric energy use and translating into approximately $147 in annual bill savings for each CCHP participant.

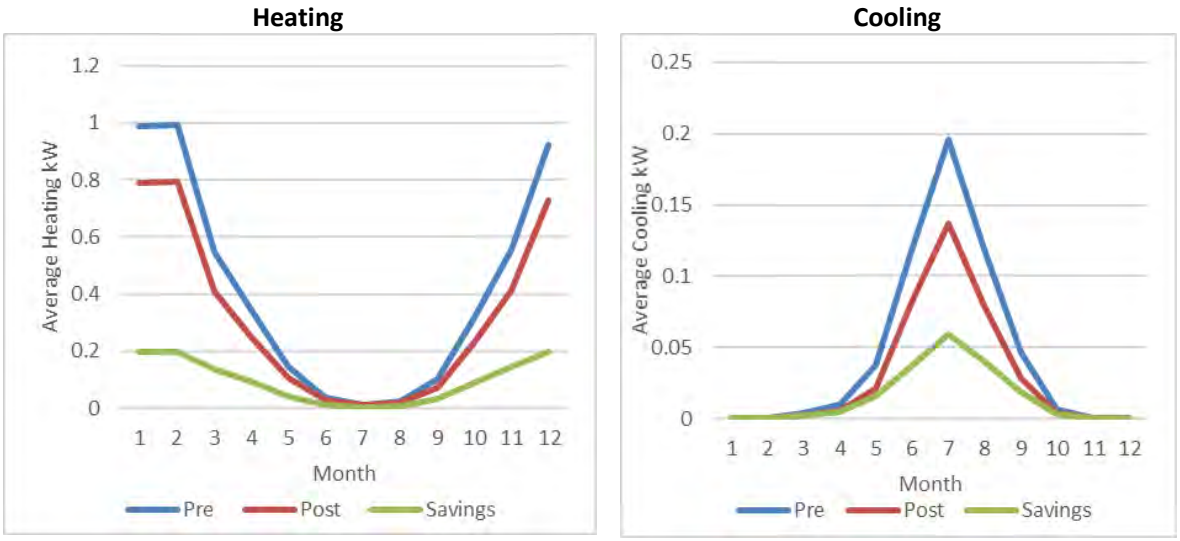
An examination of the heating and cooling load shapes and accompanying savings profile offers insight into how the CCHP impacted heating and cooling usage. Figure 21 shows the average winter and summer daily load shape and resulting CCHP savings profiles. In the winter, participants' CCHP electric energy savings were relatively consistent throughout the day. In the summer, the CCHP cooling savings were coincident with the cooling load periods of mid-to-late afternoons.

Figure 21. Participant Hourly Heating and Cooling Load and Resulting Savings



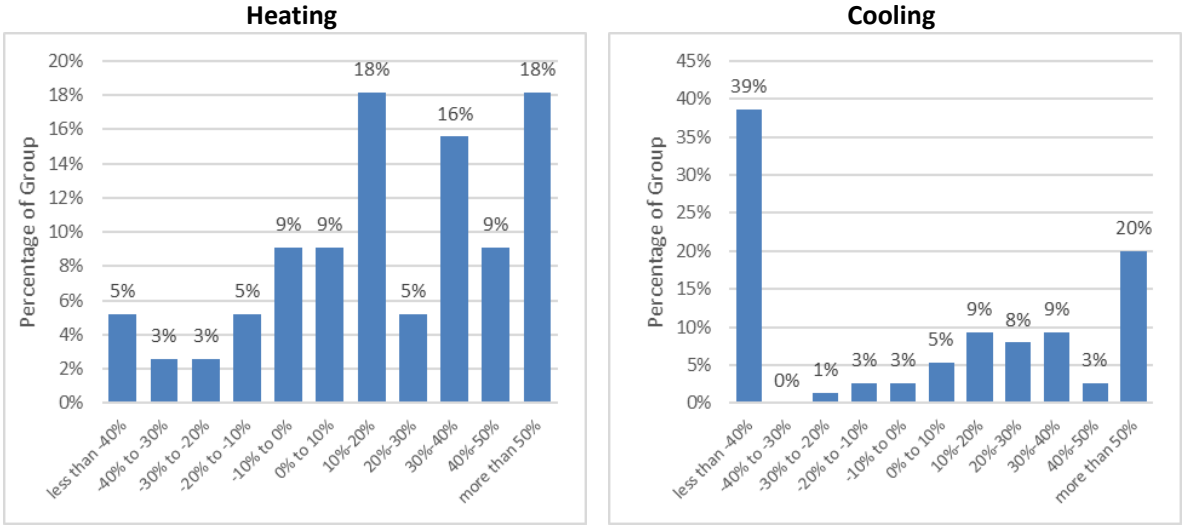
An examination of the average *monthly* load and savings profiles also showed that the savings were consistent with the monthly load shapes (Figure 22).

Figure 22. Monthly Heating and Cooling Load and Resulting Savings



The Evaluation team also explored the variability of savings across the tenant units by grouping the percentage of tenant units according to decile savings bins (incremental steps of 10% savings; see Figure 23). More than 40% of the Income Qualified Multifamily tenants saved over 30% of their pre-installation electric energy during the winter heating season, while the largest group of customers (18%) saved over 50%. On the summer cooling analysis, close to 40% of Income Qualified Multifamily customers had a net increase in summer electric use. These customers likely lacked any pre-installation cooling equipment (no room ACs) or were unlikely to have used their equipment. The second largest group of customers were also the highest saving group, with 20% of the tenants saving over 50% of their pre-installation summer cooling electricity usage.

Figure 23. Percentage Distribution of Annual Heating and Cooling Savings by Savings Bin



Benchmarking of Results

The Evaluation team compiled results from three recent multifamily heat pump retrofit program evaluations in other regions to understand how the results compared to the Consumers Energy Income Qualified Multifamily initiative. A majority of the evaluations were focused on income-qualified properties. As shown by the summary benchmark data in Table 11, the Income Qualified Multifamily initiative findings are consistent with other multifamily income-qualified billing analysis results.

Table 11. Benchmarking of Multifamily Heat Pump Billing Analysis Results

Utility and Program	Percentage Savings	Home Type	Income	Analysis Type
Consumers Energy Income Qualified Multifamily initiative	**23.2%**	**Multifamily**	**IQ**	**Billing Analysis**
2020 Commonwealth Edison Multifamily Income-Qualified Heat Pump pilot (full report not yet public but summary report is here)	25%	Multifamily	IQ	Billing Analysis
2016 Efficiency Maine Low-Income Multifamily Weatherization program (report)	22.2%	Multifamily	IQ	Billing Analysis
2014 Connecticut Energy Efficiency Fund Home Energy Services (Income Eligible) (report available online)	11% [a]	Multifamily	IQ	Billing Analysis
2014 Energy Trust of Oregon Multifamily Ductless Retrofits (report available online)	15% [a]	Multifamily	Any	Billing Analysis
Puget Sound Energy Heat Pump Dealer Channel (not public)	18% [a]	Single Family	Any	Billing Analysis

[a] This represents the percentage of annual load, not the percentage of weather-sensitive load (which was not reported).

CADMUS

Commercial and Industrial Cold-Climate Heat Pump Pilot Findings

Consumers Energy developed its Commercial and Industrial Cold Climate Heat Pump Pilot initiative in 2020 in response to the 2020 Consumers Energy Settlement Agreement with the Michigan Public Service Commission and other stakeholders. Beginning in early 2021, Consumers Energy launched the initiative targeting small commercial and industrial customers, defined as customers with facilities under 20,000 square feet. Initiative staff reached out to customers who did not have access to natural gas or were suspected to have propane heat. Staff then helped these customers choose a contractor to install a CCHP, addressed any questions the participants had throughout the installation process, and provided significant financial support to install new CCHPs; all but one customer had the entire cost fully covered.

For this research, the Evaluation team conducted in-depth telephone interviews with initiative participants to address several key research objectives:

- Explore key factors in customer decision-making regarding CCHP installations
- Explore customer experiences during the CCHP installation process
- Explore customer experiences using their CCHP
- Explore customer experiences with the initiative offering
- Identify opportunities to best support CCHP technology moving forward

In the fall of 2021, the Evaluation team conducted in-depth interviews with seven of the nine initiative participants, asking about heat pump technology awareness and motivations for participation, as well as participant experiences and satisfaction throughout the initiative process and with their new heat pump technology. During the winter of 2021/2022, the Evaluation team also metered the equipment to assess energy savings. Findings from this research are found in the 2021 Cold Climate Heat Pump Pilot Impact Evaluation Memo submitted as part of Consumers Energy's 2021 reconciliation. Metering for the 2022 cooling season is still in progress as of the writing of the report, and analysis and reporting will take place later in 2022.The remainder of this section presents findings from the participant interviews.

Participant Interviews Findings

In Fall 2021, the Evaluation team conducted in-depth interviews with seven Small C&I Initiative participants who were either the business owner or a key decision-maker related to the business. The subsections below describe how customers heard of and then decided to participate in the initiative offering, followed by installation experiences, heat pump use experiences, and overall initiative experiences and satisfaction. Additional details are available in the *C&I 2021 Cold Climate Heat Pump Pilot Customer Interview Results Presentation* submitted as part of Consumers Energy's 2021 reconciliation.

Decision-Making Processes

The Evaluation team asked participants about their awareness and understanding of heat pump technology, their plans to replace existing heating equipment, as well as their concerns, considerations, and motivations for installing the heat pumps.

Participants in the Small Commercial initiative were generally not familiar with heat pumps prior to being contacted by Consumers Energy staff. Over two-thirds of respondents (71%; n=5) were *not at all familiar* with heat pumps prior to the initiative. One respondent said they were *somewhat familiar* and had read some articles about heat pumps, but not enough to have purchased a heat pump without the support from the initiative. Another respondent said they were *very familiar* with the technology, but was under the impression that heat pumps were not suitable for Michigan winters.

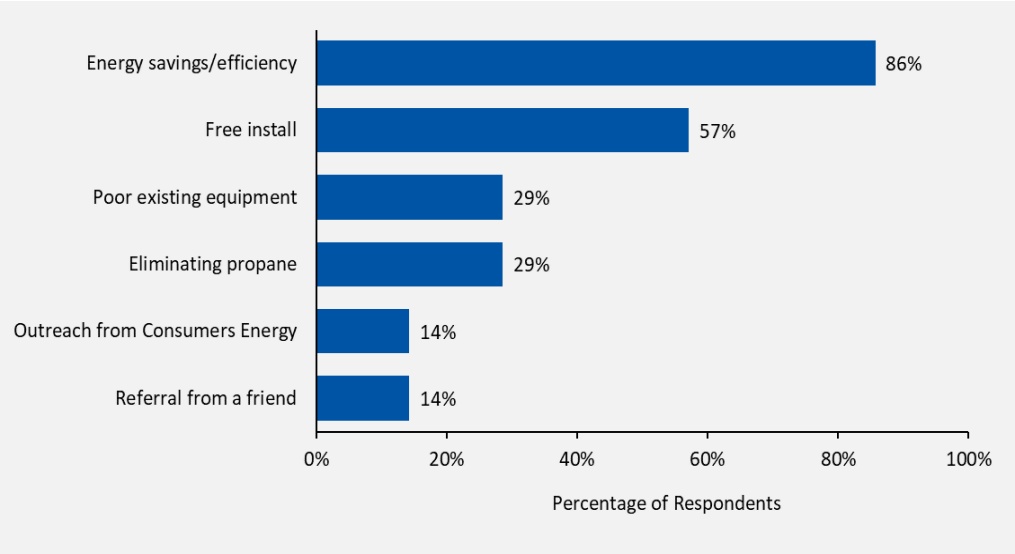
When asked about their existing heating and cooling equipment, all respondents reported having a propane furnace prior to installing their heat pumps, and 86% (n=6) had central AC. While four respondents had no immediate plans to replace their existing equipment, 43% (n=3) had planned to replace their heating equipment within the next one to three years, and all three would likely have replaced their furnace with a new propane furnace. This finding suggests that customers likely would not have considered a heat pump as an option if not for the initiative, despite some respondents reporting low satisfaction with their propane service.

When asked about their concerns and considerations when deciding to install a heat pump, respondents were primarily concerned about cost and technical considerations, while two respondents (29%) initially thought the offer was a scam: one said, “My main thing was, to be honest, I was scratching my head if it was too good to be true. I was suspicious; there are so many scams. My biggest concern [was that] I just wasn’t quite sure what was actually going on. It’s quite a good deal to get that kind of equipment.”

Respondents’ cost considerations included not knowing how much more money they would pay by switching to a heat pump, as well as how much lower their energy bill would be and how much less energy they would use. Three respondents also expressed concerns about how reliable the heat pumps would be during the winter. The following quote exemplifies this sentiment and demonstrates how this hesitancy is related to a lack of knowledge about CCHPs: “…Without knowing about the technology, we were a little concerned…about how well would the systems work in the really cold weather.”

When asked what motivated them to install their heat pump, respondents reported several motivations, mainly saving energy and the free installation, followed by the fact that the cost was largely if not completely covered by Consumers Energy (Figure 24).

Figure 24. Respondent Motivations to Install Heat Pumps



Source: Heat Pump Commercial Interview Guide Question C4. "What motivated you to agree to install the heat pump?" (n=7; multiple responses allowed)

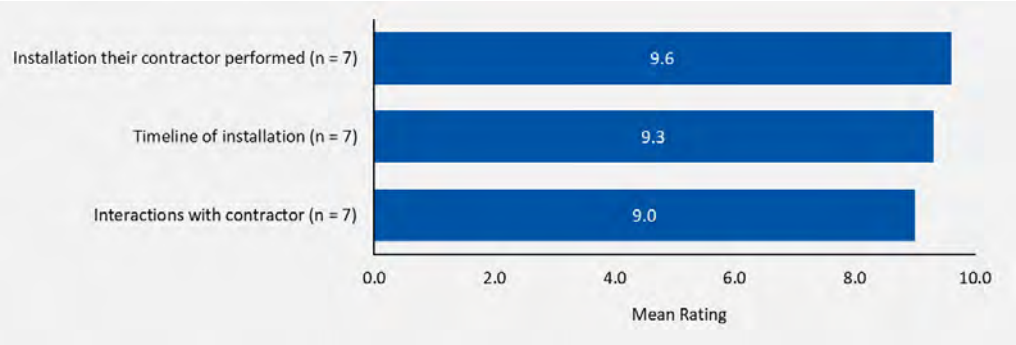
Installation Experiences

The Evaluation team also asked respondents about their experiences with finding a contractor and with having the heat pump installed. All respondents reported that it was easy to find a contractor, and none asked for multiple bids. About half of respondents (43%; n=3) preferred to use their own contractor and one respondent (14%) asked a friend who had also participated in the initiative for their contact. The other three respondents (43%) relied on contractor contacts provided by Consumers Energy: two chose a contractor they were familiar with from the list (and, as mentioned previously, Consumers Energy tailored this list to include trade partners they knew had experience with heat pumps). These findings indicate that the initiative resources for finding a contractor were effective.

Overall, respondents reported having a positive experience with their contractor, with 86% (n=6) saying they would use the same contractor again. All the respondents also reported that the contractors they worked with appeared to be knowledgeable about heat pumps, and 57% (n=4) said the contractor was *very knowledgeable*: "Extremely [knowledgeable] and very helpful and explained it all to me very well… They were fast, efficient, and did exactly what they were going to do in the time they said they were going to do it. They did a great job."

Average satisfaction with contractor interactions was a 9 on 10-point scale, where 1 meant *unacceptable* and 10 meant *outstanding* (as shown in Figure 25). Though respondents were generally satisfied with their contractors, two of the seven respondents (29%) expressed some dissatisfaction. One of these respondents specified that the contractor should have been more communicative about the project schedule and timeline but said they would still hire the contractor again because they would not know who else to hire. The other respondent was less satisfied with their interactions with the contractor and were not sure they would hire them again.

Figure 25. Installation Experiences Satisfaction Averages



Source: Heat Pump Commercial Interview Guide Questions G1a, G1b, and G1d. Please see *Appendix F* for specific question wording.

Respondents were also satisfied with the timeline of their installation. While about half of respondents (57%; n=4) reported some delay with their project timeline, it did not impact their overall satisfaction. However, some reported that if the installation had occurred during a time when they needed their heating or cooling, they would have been more dissatisfied. Heating or cooling needs were not pressing since these customers either had working equipment or their installation was completed in the shoulder season, as evident by the following statements:

- "It might have been different if we didn't have heat or air and every day was a struggle, but it was early spring… so it wasn't an issue, so we weren't pressed to hurry up and get this into service."
- "I'm glad they didn't do it in the winter, because then I would have been irritated [with the delayed project timeline]."

Most of the heat pump installations went smoothly, with respondents rating their satisfaction with the installation process as an average of 9.6 out of 10, as shown in Figure 25. When asked if there were any challenges with installing their heat pump, only two respondents reported some minor challenges related to the equipment not functioning properly at first and unforeseen installation issues. All respondents said that they received a new thermostat as part of their CCHP installation, and about half (43%; n=3) required new duct work. Slightly more than half of respondents (57%; n=4) reported that they have a back-up heating system in addition to the CCHP system. Of those four, two kept their old heating and cooling equipment, one just kept their old back-up heating, and one installed a new propane furnace as a back-up.

Experiences Using Heat Pumps

Due to the timing of this initiative and the research effort, respondents had primarily used their heat pump during the summer months and had used only the cooling function; however, some respondents (71%; n=5) reported that the heating function had come on during colder mornings in September or said they had been able to use the heat briefly in early spring. In general, respondents were very satisfied with their new heat pump and its operation, with an average satisfaction rating of 9.3 out of 10. While respondents were already generally satisfied with the equipment, a few customers noted being hesitant

to give the heat pump a higher rating until after using the heating function more consistently in colder weather. The Evaluation team conducted follow up interviews with Small Commercial initiative participants as part of on-site impact evaluations completed following the 2021/2022 winter heating season to assess participant experiences with the heat pumps in cold weather. [17]

Despite high satisfaction with heat pump performance, almost half of respondents (43%; n=3) reported some minor issues with their heat pumps, including not cooling down to the expected temperature and two issues with the installation that required a contractor to fix. The biggest challenge customers reported was needing to learn how to use their new smart thermostat; this finding was echoed in the winter heating impact analysis, which revealed that some customers would benefit from additional training or support to optimize heat pump controls and settings to maximize savings. These findings suggests that customers easily adapted to their new technology but could use some higher touch support during the first few weeks or months after installation to confirm that all the equipment is performing well and that the customer knows how to use the equipment properly.

Initiative Experiences and Satisfaction

When asked about their overall initiative experience, most respondents said they were *very satisfied* with their participation in the initiative. Most respondents (86%, n=6) had initially learned about the initiative offering from Consumers Energy staff and all seven reported that they had received excellent support throughout their participation. While respondent motivations for deciding to participate in the initiative included the fact that the equipment and installation were free, the support and persistence from Consumers Energy staff was also a motivating factor.

> "Just the willingness that they had to do this for just a small [facility] was huge […] People don't just give stuff away, and [a new heating system] was definitely something that was needed, and we would have had to purchase it in the future."
>
> -Respondent

Respondents' overall satisfaction with the pilot was an average of 9.9 out of 10, and 86% of respondents (n=6) *strongly agreed* that Consumers Energy made it easy to participate in the initiative. When asked if they were likely to recommend Consumers Energy to a friend or colleague if they had a choice in energy providers, most respondents (71%; n=5) said they were extremely likely to do so. The two respondents who gave lower ratings said that it was only because their utility is not something they really think or talk about. One satisfied respondent compared Consumers Energy to the utility that provides electricity at their home: "I've always had great service with Consumers [Energy]. I've had less outages and …anything I need for my business, I'm able to get immediate responses."

Appendix A. Survey and Interview Methodology and Details

This appendix provides survey and interview details and methodologies by initiative or stakeholder.

Contractor Interviews

Consumers Energy provided the Evaluation team with a sample of 177 contractors who had engaged with Consumers Energy HVAC energy waste reduction offerings at some point, but who had not participated in the CCHP Initiatives. The sample did not include any information regarding the number or type of projects completed by the contractor, so the Evaluation team was unable to stratify the sample in any meaningful way. As such, recruitment of contractors proceeded randomly until research quotas were satisfied. We interviewed a total of 11 contractors for this research.

Table A-1 includes contractors' company information such as type, number of projects per year, and products offered.

Table A-1. Interviewed Contractor List

Company Location	Customer Base	Number of Projects/Year	Average Heat Pump Installation/Year
Ada	Primarily residential, more high-end homes	~100	<5 ducted systems >20 mini-splits
Allen Park	Residential multifamily, some single family, very little commercial	1,000–1,500	75 since last fall
Allendale	Data not collected	Data not collected	Data not collected
Benzonia	90% to 95% residential, lots of big homes on shore of Lake Michigan used as seasonal residences; a little bit of multifamily, a little low income	200 installs	20–30
Dearborn Heights	Mostly residential, some multifamily	100	3 last year
Jackson	50% residential, 50% commercial	200–225	6–8 ducted systems >50 mini-splits
Livonia	Primarily (75% or more) income-qualified multifamily, with client that is the largest affordable housing provider in Michigan	5–10 projects per year 100–300 pieces of equipment	10–20 mini-splits per year (primarily server rooms and elevator machine rooms)
Okemos	60% residential and 40% commercial, lots in the city, also lots of dual-fuel applications with propane and lots of air-to-air and geothermal projects	~1,000	~100 in 2020, 80% air-to-air 24 mini-splits in the past year
Parma	Residential and some multifamily (very little commercial)	150–200 pieces of equipment	<10
Sparta	75% residential, commercial is mostly service maintenance, with a rare design/build	~100	12–15 per year for ASHPs and mini-splits.
Warren	50% residential and 50% commercial	200	<5

Distributor and Manufacturer Interviews

The Evaluation team interviewed five distributors and two manufacturers involved in the production and distribution of CCHPs (including mini-split heat pumps) in Michigan. We fielded the interviews via telephone, and each took 30 to 45 minutes to complete. The team recorded and transcribed each interview to assist with our analysis. To motivate manufacturers and distributors to participate, we offered a $75 incentive to each respondent in the form of an Amazon, Target, or Meijer gift card or a donation to a local United Way.

Sampling

For this effort, the Evaluation team specifically targeted manufacturers who have supplied equipment for Consumers Energy programs and associated distributors in Michigan that supply CCHPs produced by these manufacturers. The list of manufacturers and distributors interviewed is shown in Table A-2.

Table A-2. Interviewed Distributor and Manufacturer List

Company Type	Role of Interviewee	Primary Brands Offered	Primary Types Offered	States/Regions Served
Manufacturer	Manager, Utility & Efficiency Programs	(Confidential)	Mini-split	Central U.S.
Manufacturer	Regional Representative	(Confidential)	Mini-split	MI, OH, PA, WV
Distributor	President	Robur	Absorption	MI, OH, IN
Distributor	Director of HVAC Services	Mitsubishi, Rheem, Trane	Mini-split	MI, OH, Eastern U.S.
Distributor	Territory Manager	Trane, Mitsubishi	Mini-split, unitary	MI
Distributor	Regional Sales Manager	LG, Rheem, Bosch	Mini-split, unitary	MI, OH, IN, PA, WV
Distributor	Owner	Daikin, Amana	Mini-split, unitary	MI, WI, IL, IN, OH, PA

The team sampled distributors from a contact list provided by Consumers Energy staff as well as from internet searches for distributors associated with key manufacturers. Additionally, the Evaluation team asked for referrals for distributors during interviews with contractors. We targeted distributors such that representation across manufacturers was roughly equal (ensuring that interviewed distributors do not represent one manufacturer more than another).

Recruiting

The Evaluation team reached out to manufacturers and distributors by phone to schedule interviews. During phone recruitment, we explained the research and provided an Evaluation team contact person so the organization could reach out if they had additional questions or were interested in scheduling an interview. The team primarily used email to recruit referrals, which similarly included an explanation of the research and a request for scheduling an interview.

Profile of Distributors and Manufacturers

Table A-2 above shows respondent information including company type, the role of the interviewee at the company, primary brands offered, types of CCHPs offered, and regions served. Most interviewees represented mini-split CCHP technology and were responsible for operations in several states.

Residential Market Rate Participant Surveys

The Evaluation team sent a survey invitation to the census of 29 Residential Market Rate pilot participants in November 2021. The email survey invitation included a $15 incentive for taking the survey. The Evaluation team sent two reminder emails; after one week and after two weeks. Nine of the 29 participants completed the survey, for a 31% response rate: with such a small sample size, the results should be interpreted with caution and only viewed as directional indications (not intended to be analyzed with statistical confidence).

Income Qualified Multifamily Property Manager and Owner Interviews

The Evaluation team conducted in-depth telephone interviews with three site contacts (a construction manager, a resident manager, and an owner) in November 2021. Each interview lasted approximate 30 minutes. We targeted owners and managers of income-qualified multifamily properties who had participated in the Consumers Energy Income Qualified Multifamily initiative. Franklin Energy provided PMO contact information, including email address and phone numbers, for Evaluation team outreach and recruitment.

The Evaluation team initially distributed emails to six property site contacts and attempted phone recruitment for the seventh due to a missing email address. Though the team made three email attempts, the emails did not result in any successful recruitment for the interviews. The Evaluation team then pivoted to making recruitment calls from Monday through Friday, mid-morning to early evening, calling each number a maximum of five times.

With an interview target for a census (seven) of participating PMOs, the actual number of three interviewed PMOs was consistent with expectations, even with an increased incentive of $150 to make the interview more attractive for potential participants.

Income Qualified Single Family and Multifamily Participant Surveys

The Evaluation team collected feedback from 32 multifamily tenant surveys in November 2021. The email survey invitation included a $15 incentive for taking the online survey. We targeted tenants of income-qualified multifamily properties who had participated in the Consumers Energy heat pump offering. The Evaluation team did not have access to participating tenant contact information, so we attempted to identify tenants through two distinct efforts. First, the team relied on existing income-qualified tenant records to match CCHP properties based on physical address. Using this approach, the team identified 46 potential income-qualified multifamily tenants to recruit. Second, during the team's interviews with multifamily PMOs, we asked and all three PMOs if they were willing to distribute the survey recruitment email to their tenants. This second approach resulted in the potential for 90 additional tenant respondents, though the Evaluation team is unsure of the final count of emails distributed by the PMOs.

The Evaluation team solely relied on email distribution to recruit tenants for the online-only survey. Though the team made three email attempts for the address-matched income-qualified tenant group, the emails combined with the PMO email recruitment effort resulted in 32 successful recruitments for the surveys, for a response rate of 24% (32 of 136).

Small Commercial Participant Interviews

The Evaluation team conducted in-depth telephone interviews with seven business owners and decision-makers in September and October 2021. Each interview lasted approximately 30 to 45 minutes and we offered respondents a $75 gift card for their time. We targeted owners and decision-makers of small commercial and industrial facilities (<20,000 square feet) who had participated in the Consumers Energy Small Commercial initiative offering. Consumers Energy provided these decision-makers' contact information, including email address and phone numbers, for Evaluation team outreach and recruitment. The interview guide was reviewed and approved by Consumers Energy staff to ensure that questions were consistent with their expectations and reflected the issues of interest to Consumers Energy.

The Evaluation team recruited customers via email and phone. Due to the small sample size of nine participants, we attempted to recruit the entire sample with a minimum goal of five completes. The Evaluation team was able to recruit seven of the nine participants, with a response rate of 78%. An eighth participant was interested in participating but their heat pump had not been installed yet, so they were not able to answer questions about the full experience. The ninth participant was unreachable after a total of five contact attempts via email and voicemail.

CADMUS

Appendix B. Impact Analysis Methodology and Details

This appendix provides the methodology and details related to the Residential Market Rate pilot engineering analysis and the Income Qualified Multifamily initiative billing analysis.

Market Rate Engineering Methodology

The Evaluation team conducted an engineering analysis of the impacts from the Residential Market Rate pilot and relied on MEMD assumptions and information we had collected on customer data such as such as home vintage, presence of central cooling, installed system COP at 5°F, rated HSPF and SEER, tonnage, and other data. The Evaluation team relied on the MEMD weighting tool, which generates single measure outputs based on home vintage, climate zone, sizing, and efficiency levels.

The MEMD building simulation data provided end-use level consumption details broken out by the seven Michigan climate zones (Alpena, Detroit, Lansing, Muskegon, Saginaw, Sault Ste. Marie, and Traverse City) and three building vintages (old, average, and new). The Evaluation team used the MEMD building simulation end-use consumptions for ASHP heating, ASHP electric resistance back-up heating, and ASHP cooling to calculate pre– and post–CCHP equipment consumption on a per-ton basis. We then adjusted these end-use consumptions using COP from ASHP federal standard HSPF and SEER values to reflect site-specific equipment. We used several types of CCHP-collected site data in the analysis:

- Home vintage
- Presence of central AC
- Home heating fuel type
- Home heating equipment type
- Premise zip code
- CCHP details: quantity, COP at 5°F, HSPF, SEER, and tons

Since existing space heating equipment data collection was limited to fuel type, the team assumed that existing equipment represents federal standard equipment (in AFUE) and represents a 50/50 average of boilers and furnaces, if applicable. The Evaluation team created this split because the data field for system type collected was either “Furnace/Boiler” or “Resistance.” The difference in federal standard efficiency is minimal: 0.8 for furnaces and 0.82 for boilers. Therefore, the team used 0.81 AFUE.

We also assumed that existing central cooling equipment represents the federal standard SEER value. For homes without central cooling, we assumed that a portion of homes use room or window AC units to provide a portion of cooling, and we based this portion of homes on *2015 Residential Energy Consumption Survey*[18] data for the East North Central census division. The Evaluation team used data

[18] U.S. Energy Information Administration Residential Energy Consumption Survey 2015 Data Website: https://www.eia.gov/consumption/residential/data/2015/

from the Consumers Energy 2021 *Electric Energy Waste Reduction Potential Study*[19] to develop a ratio of room AC tonnage for single family homes when compared to a central system (since the room AC unit likely did not provide cooling load equivalent to the CCHP system). Like with central ACs, we assumed the room AC efficiency to represent the federal standard EER value.

Since no sizing information was collected on the sites about the existing HVAC systems, the Evaluation team assumed equivalent kBtu per hour heating or cooling tonnage as the CCHP, except for existing room AC sizing (for which we made an adjustment). Therefore, results only reflect offset heating and cooling load by the CCHP, and not total household heating and cooling load.

We used two data points to map MEMD 2019 data to the site-specific data: "Approximate House Age" and "Premise Zip." The household age was a one-to-one match with MEMD vintages, and therefore was a simple mapping lookup. The Evaluation team mapped the zip codes nearest to the available MEMD weather station based on distance and engineering judgment for weather impacts. With these two site-specific data points—vintage and zip code—we were able to map the MEMD 2019 building simulation consumptions to each specific site.

To adjust the MEMD 2019 ASHP end-use consumptions to reflect the existing equipment on a per ton basis, the team applied COP adjustments using the federal standard definitions outlined above. To adjust the MEMD 2019 ASHP end-use consumptions to reflect the CCHP equipment, we performed a more detailed analysis (as additional equipment data was available). Using typical meteorological year version 3 (TMY3) 8760 hourly data for each MEMD modeled reference city, we performed hourly bin analysis to determine hours based on temperature bins in 5°F buckets. Assuming the HSPF value reflected performance at 47°F, the team developed a linear relationship using the COP at 5°F system performance data. We capped this linear relationship during cold temperatures to not be less than 1 COP, representing 100% electric resistance performance. Using the hourly bin analysis data by 5°F buckets and assuming CCHP heating did not occur above 65°F, the Evaluation team developed a weighted average CCHP HSPF efficiency to represent annual heating performance of the CCHP specific to the unit installed. We then used the weighted average CCHP HSPF and SEER values to adjust MEMD 2019 ASHP end-use consumptions to reflect CCHP performance on a per-ton basis. In order to represent total heating and cooling load, we multiplied the CCHP installed tonnage by the pre/post heating and cooling loads per ton.

The Evaluation team relied on Consumers Energy 2021 residential natural gas and electric marginal rates (per kilowatt-hour and per therm), which include all surcharges for single-family customers. The team used previously developed load shapes to reflect equipment usage during peak and non-peak periods for the electric bill impacts. We created annual electric fuel costs by applying each specific equipment type's consumption load shape to the peak and off-peak rates. For fuel oil and propane costs, the

[19] 2021 Energy Waste Reduction Electric Potential Study Report: https://cadmus.sharepoint.com/sites/collaboration/6409-P01/ces/Shared%20Documents/Final%20Reports/2021/Electric%20Potential%20Study/2021%20Energy%20Waste%20Reduction%20Electric%20Potential%20Study%20Report%20FINAL%202021.06.10.pdf

Evaluation team used the latest Michigan monthly data from U.S. Department of Energy resources. These fuel costs utilized in the impact analysis are shown below in Table B-1.

Table B-1. Market Rate Fuel Costs Utilized in Impact Analysis

Fuel Type	Cost
AC_Central Loadshape - Electricity with Surcharge	$0.18
AC_WallWindow Loadshape - Electricity with Surcharge	$0.18
ASHP Loadshape - Electricity with Surcharge	$0.17
ZONAL_ER_HEAT Loadshape - Electricity with Surcharge	$0.16
AC Central Load Shape - Electricity with Surcharge	$0.18 per kWh / $52.48 per MMBtu
AC Wall Window Load Shape - Electricity with Surcharge	$0.18 per kWh / $52.19 per MMBtu
ASHP Load Shape - Electricity with Surcharge	$0.17 per kWh / $48.57 per MMBtu
Zonal Heat Load Shape - Electricity with Surcharge	$0.16 per kWh / $48.18 per MMBtu
Propane	$2.44 per gallon / $26.71 per MMBtu
Fuel Oil	$3.10 per gallon / $22.56 per MMBtu
Natural Gas	$7.91 per thousand cubic feet / $7.62 per MMBtu

Electric and natural gas rates used from Consumers Energy.

Multifamily Billing Analysis Methodology

To estimate electric energy usage changes within the Income Qualified Multifamily initiative projects, the Evaluation team designed and conducted a statistical billing analysis. The team relied on historical advanced metering infrastructure (AMI) interval data to estimate facility-wide and per-tenant-unit savings associated with CCHP installations using the Princeton Scorekeeping Method. The team incorporated TMY3 data to normalize usage and control for weather. We also included a nonparticipant comparison group, selected from other income-qualified electrically heated multifamily nonparticipants to control for the impacts of nonprogrammatic factors (such as changes in economic conditions including COVID-19–related behavior changes).

Data Sources

The Evaluation team requested and compiled participant and household data for the CCHP billing analysis from several sources:

- ***Heat pump initiative tracking data.*** The team received initiative tracking data from the implementation contractor to identify CCHP properties. These initiative tracking data included all participants from March 2020 to December 2020, including property name, participation dates, building square footage, and heat pump efficiency and capacity ratings. The tracking data did not include specific tenant unit addresses or the specific account information connected with each tenant.
- ***Multifamily composite database.*** The team developed a multifamily database to identify multifamily properties based on property size for prior 2020 evaluation research, which we used to identify all unique addresses (and all accounts associated with each property), including tenant units.

- ***Electric AMI data.*** Consumers Energy provided electric AMI data for all properties that had identifiable account data. This included meter read dates and times and all kilowatt-hour usage, by account, between June 2019 and September 2021.
- ***Michigan weather data.*** The team collected average hourly temperatures from June 2019 through September 2021 for four weather stations corresponding to the nearest monitoring station locations associated with CCHP participants. We matched hourly heating degree hours (HDHs) and cooling degree hours (CDHs) to AMI data read dates and times, and compiled hourly TMY3 15-year normal weather averages from 1991 through 2005 from the National Oceanic and Atmospheric Administration to assess energy usage under normal weather conditions.

Data Processing

The Evaluation team conducted several data processing steps to review, validate, and transform the raw AMI and tracking data into an analysis dataset:

- Imported and cleaned the tracking, AMI, and weather station datasets into Statistical Analysis System software
- Merged tracking and AMI datasets using account ID
- Filled in missing or zero AMI data readings with averages based on similar day-types or as the average of the previous and following hours
- Checked the hourly AMI histories for problems such as vacancies, outliers, and too many missing/interpolated readings
- Mapped each property to the nearest weather station using the property zip code
- Used hourly temperatures to determine variable base HDHs and CDHs for each station
- Merged the HDHs and CDHs onto the AMI and tracking data, using respective dates and times for each account
- Matched TMY3 HDHs and CDHs from the nearest station to weather-normalize the AMI data

Participant and Nonparticipant Groups

For the AMI analysis, the Evaluation team assigned properties into participant and nonparticipant groups. To be selected for the participant group, all multifamily heat pump properties had to have a continuous nine-month period of available usage data both before and after their participation in the pilot. The team used a rolling specification to assign pre- and post-periods, identifying a range of months around the installation period for each participant. Starting with a census of participants from the March through December 2020 period (initially seven properties), the Evaluation team identified a final participant group for analysis (after screening for participants who had at least nine months of pre-period and post-period billing data). We conducted account-level reviews of pre- and post-period usage for all individual participants to identify anomalies (periods of vacancies or other anomalies) that could bias the results. The team also applied additional screening criteria, described in detail in the *Data Screening and Model Attrition* section.

The team used a comparison group of nonparticipants to account for exogenous factors that may have occurred coincident with heat pump initiative activities. These factors can include macroeconomic effects, COVID-related behavior or occupancy changes, or other interactions that may have affected energy usage outside the heat pump influence. The Evaluation team identified comparison groups using customers who we had identified as living in income-qualified electrically heated multifamily properties. After creating the eligible group of nonparticipants, we further refined the nonparticipant group by matching each property to a participant property based on pre-installation usage. This assisted us in creating groups with baseline usage profiles as similar as possible to those of participants.

Disaggregation

Consumers Energy had the Evaluation team focus the heat pump analysis on electric-heated properties to create savings associated with reducing electric heating and cooling loads. Because of the focus on electric heating and cooling loads, the Evaluation team disaggregated the billing data to isolate the weather-sensitive electric heating and cooling usage from overall annual electric usage (which may include water heating, cooking, plug load, and lighting usage). First, we estimated weather-normalization models for each customer in the pre- and post-installation periods using actual observed weather data. Then we estimated the weather-sensitive components of electric usage using TMY3 data. Finally, we estimated the heating- and cooling-related components of usage.

Data Screening and Model Attrition

Data anomalies, outliers, missing data points, incomplete records, and other data issues all introduce potential bias into a billing analysis. The Evaluation team used several rules to flag and then remove accounts that failed to meet certain conditions:

- ***Must have sufficient pre- and post-installation billing data for analysis.*** All accounts had to contain a minimum of nine months of pre- and post-installation usage data.
- ***Must have a pre- and post-installation change within 70%.*** All accounts showing post-installation usage changes of up to 70% of pre-installation usage were retained in the analysis.
- Must not be an outlier or vacancy. The Evaluation team performed account-level reviews of pre- and post-installation period usage for all individual participants and removed anomalies (such as periods of vacancies) that could bias the savings results. We also removed units that participated in another energy-efficiency program from the analysis, as we could not determine which project created the observed savings.

The data screening resulted in a final analysis sample of three unique participant properties representing 77 tenant units. This corresponds to just under half (43%) of the original participating properties. As shown in Table B-2, the largest source of attrition for the billing analysis of participants originated from removing vacancies from the analysis, primarily because the billing data was only available for accounts that were active at the time of the request. Many of the accounts that were currently active did not have the necessary historical usage data at the apartment unit level to be included in the analysis. For the nonparticipant group, the single largest source of attrition resulted from units that did not show an electric heating signature.

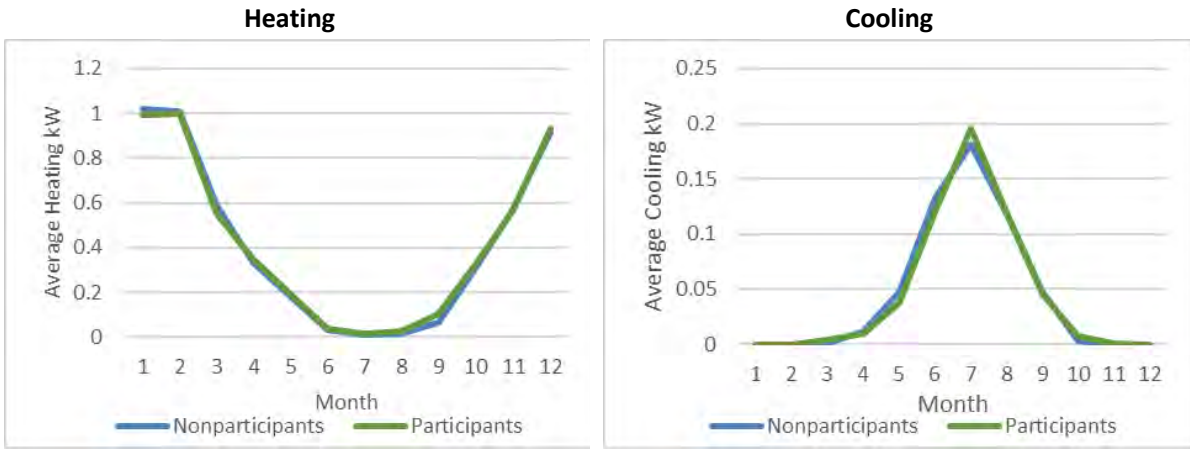
Table B-2. Income Qualified Multifamily Heat Pump Billing Analysis Summary Attrition

Screen	Participants	Nonparticipants
Initial Requested Sample	**97**	**2,329**
AMI Data Available	96	2,308
Sufficient Pre-Post Data	94	2,192
Removed Outliers/Vacancies	84	1,733
Matched Nonparticipant Property Type to Participant Property Type (such as removed high rise and mobile homes)	84	1,583
Determined that Dwelling Used Electric Heating	84	145
Passed Pre-Post Hourly PRISM Models/Hourly Prediction	84	132
Change within 70%	77	119
Matched Usage to Participants	77	112
Final	**77**	**112**

Baseline Electric Energy Use

Baseline multifamily building electric usage—the whole-building electric usage before installing energy-efficiency upgrades—is a critical input to whole-building energy savings estimation for electric-heated properties. The Evaluation team, using hourly PRISM (Princeton Scorekeeping Method) weather normalization and energy load disaggregation models, estimated the annual and monthly heating and cooling loads for the Income Qualified Multifamily participating tenant units. Additionally, estimating baseline heating and cooling energy usage across both participating and nonparticipating tenant units allows for isolating initiative-induced impacts specific to heat pump installation. This is important, as it accounts for non-programmatic influences on energy use, controlling for occupancy changes, behavior changes, changes attributable to COVID-19, and any other non-programmatic changes. A summary of the monthly average heating and cooling loads (in average kilowatts) across the participants and nonparticipant groups is shown in Figure B-1. There is little discernable difference—and, more importantly, no statistically significant difference—between participants' and nonparticipants' monthly heating and cooling loads.

Figure B-1. Baseline (Pre-Installation) Annual Heating and Cooling Load



The Evaluation team, with access to tenant apartment electric usage, estimated an average weather-normalized pre-installation baseline tenant unit usage of 3,860 kWh. Table B-3 shows the breakdown of the heating, cooling, and annual baseline pre-period annual weather-sensitive usage (per tenant apartment). As expected, given that multifamily tenant units in the CCHP were electrically heated, heating electric energy use is the predominant component (approximately 94%) of annual weather-sensitive use in these units.

Table B-3. Participant Tenant Unit Pre-Period Baseline Electric Weather-Normalized Per-Unit Usage

Usage Type	Weather-Sensitive Annual Usage (kWh)	Heating Usage (kWh)	Cooling Usage (kWh)
Billing Analysis	3,860	3,626	234

Source: Evaluation team AMI billing analysis.

Assess Change in Energy Use

As the final step in the analysis, the Evaluation team estimated real world changes to energy use between pre-and-post-installation usage patterns for participants and nonparticipants. Energy savings are the difference between participants' and nonparticipants' energy usage between the pre- and post-installation periods.

Engineering Calibration and Validation

The Evaluation team benchmarked the billing analysis findings relative to values produced from a simplified heat pump engineering model and the initiative-claimed savings (the initiative relied on current MEMD savings estimates). The goal of benchmarking was to help frame the billing analysis findings and understand how close the changes to energy usage tracked with alternative sources. The Evaluation team compiled initiative tracking claimed savings from eTracker and normalized the savings at the tenant apartment unit level by using the total number of installed heat pumps, the claimed savings, and the total number of apartment units. The team relied on the heating load requirement (3,626 kWh), assumed a CCHP COP of 2.75, and entered this data into a simple algorithm expressing continued baseboard heating, CCHP heating, and total heating demand based on several different displacement scenarios (Table B-4).

Table B-4. Cold-Climate Heat Pump Simplified Engineering Estimate

DHP Heating Load Displacement	Baseboard kWh	CCHP with COP of 2.75 (kWh)	Savings (kWh)	Total kWh
100%	-	1,319	2,307	3,626
75%	907	989	1,731	3,626
50%	1,813	659	1,154	3,626
36%	2,319	475	832	3,626

Bill Savings Estimation

To estimate the bill savings attributable to the CCHPs installed in the multifamily tenant units, the Evaluation team estimated the bill savings occurring during the time-differentiated bill periods across the year. According to residential rate data, peak period rates occur in summer months, from May 1 through September 30, during weekdays from 2 p.m. to 7 p.m. The Evaluation team then estimated the savings occurring during the peak and off-peak periods. Table B-5 shows a summary of the seasonal peak and off-peak rates and savings.

Table B-5. Cold-Climate Heat Pump Bill Savings Calculations

Residential Rate	Residential Billing Rate ($)	Income Qualified Multifamily CCHP Savings Occurring During Each Period (kWh)	Bill Savings ($)
Summer Peak	$0.213	6.1	$1.30
Off-Peak	$0.164	889.9	$145.94
Total Bill Savings			**$147.24**

Electric Savings: Engineering Comparison

The Evaluation team developed a simplified engineering estimate to compare how the evaluated electric savings compared with anticipated savings from a CCHP and added the initiative-claimed savings based on MEMD measures. Table B-6 shows a comparison of Income Qualified Multifamily initiative savings from the billing analysis sample, two engineering estimates based on two different displacement scenarios, and the initiative MEMD claimed savings estimate. The billing analysis estimate showed lower realized savings relative to the engineering estimate (assuming 50% of the electric baseboard heating was displaced by the CCHPs) and the MEMD estimate. In order for the engineering estimate to match the billing savings estimate of 832 kWh of heating load savings, the CCHPs would need to displace just over one-third (36%) of the heating load, which therefore assumes that the legacy baseboard heating systems still account for the majority of heating load for the apartments. The continued use of baseboard heat is consistent with feedback from the tenant survey, in which tenants reported continued use of baseboard heat as their primary heating source.

Table B-6. Annual Per–Tenant Unit Cold-Climate Heat Pump Electric Weather-Sensitive Savings Estimates Comparison

Source	Weather-Sensitive Usage (kWh) (A)	Weather-Sensitive Savings (kWh) (B)	Savings versus Weather-Sensitive Usage (%) (B / A)
Billing Analysis	3,860 (Annual)	896	23.2%
Billing Analysis	3,626 (Heating)	832	22.9%
Engineering @ 50% Displacement [a]	3,626 (Heating)	1,154	31.8%
Engineering @ 36% Displacement [a]	3,626 (Heating)	832	22.9%
MEMD/Pilot Claimed Savings [b]	3,860 (Annual)	1,474	38.2%

[a] This is an engineering estimate based on the heating season only and derived from AMI billing analysis.

[b] This represents annual weather-sensitive usage from the AMI billing analysis.

CADMUS

Appendix C. Consumers Energy Heat Pump Market Rate Customer Survey

Objectives	Research Questions	Question Number
Assess customer awareness and motivations to install heat pumps	Were participants aware of heat pumps prior to participating in the offering? How do customers learn about heat pumps? What are participants' motivations for installing a heat pump? What are important decision factors for installing a heat pump? How much rebate is required to motivate participation?	Section B
Assess participant installation experience	How did participants experience the installation? Are there opportunities to improve the installation experience?	D1–D3
Document participant perceptions of heat pumps, energy or cost savings, comfort levels, and satisfaction	What are participants' experiences with heating/cooling comfort? How satisfied are participants with the heat pumps and the offering? How satisfied are participants with Consumers Energy?	D4–D12, B1, B2
	What non-energy benefits did the offering generate (such as reduced bill impacts, enhanced comfort levels, and improved operational issues)?	D11
Document participant usage behavior and home characteristics	How do respondents manage energy use at the thermostat?	Section C
	What are participants' home characteristics?	Section E

Survey Overview: The Evaluation team administered an online survey to residential customers who received a new heat pump. Then the team sent an email with a link to the survey, followed by reminder emails to encourage households to complete the survey withing the desired timeframe. In addition, the Evaluation team offered participants a $15 Meijer or Amazon.com gift card for completing the survey.

Target Audience: Census of Residential Market Rate pilot participants who installed a new heat pump as part of the Consumers Energy heat pump offering.

Survey Introduction and Purpose

Welcome, thank you for taking a few minutes to provide feedback about your cooling and heating equipment. Your feedback is very important to us and will help us improve rebates and incentives for new products that help customers save energy. This survey should take about 10 minutes. Your responses are confidential and will be used for research purposes only.

Be sure to enter your name and address at the end of the survey to receive your $15 Meijer or Amazon gift card as our thanks.

Click on the Next and Back buttons at the bottom of each page to navigate through the survey.

A. *Screener*

A1. Our records indicate that you received a rebate for a heat pump installed in your home. Is this correct?
1. Yes
2. No **[TERMINATE]**
98. Don't know **[TERMINATE]**

A2. Approximately how long have you lived in your current home?
1. Less than one year
2. One to three years
3. Over three years

A3. **[If A2=1]** Were you living in your current home when the heat pump was installed?
1. Yes
2. No **[TERMINATE]**

TERMINATION MESSAGE: This survey is for Consumers Energy customers who received a rebate for a heat pump through the heat pump rebate program and who were living in the home when the heat pump was installed. Thank you for your interest in participating in this survey.

B. *Current Company Metrics and Awareness*

We'd like to ask some questions about your opinions toward Consumers Energy.

B1. How likely would you be to recommend Consumers Energy to a friend or family member if you had a choice in energy providers?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

B2. Please describe in detail why you gave that rating. _____

With these next questions, we would like to know more about your experience with heat pumps.

B3. Were you familiar with heat pumps before deciding to purchase and install the heat pump?
1. Yes
2. No
98. Don't know

B4. **[DISPLAY IF B3=1]** Prior to participating in this offer, had you ever had a contractor recommend a heat pump?
1. Yes, I had a contractor recommend a heat pump
2. No, a contractor has never recommended a heat pump to me

B5. Before you participated in this offer, were you aware that Consumers Energy offered rebates for heat pumps?

1. Yes, I was aware of heat pump rebates
2. No, I was unaware of heat pump rebates

B6. How did you first learn about the heat pump rebate? Please select only one response. **[RANDOMIZE 1–6]**

1. Contractor recommendation
2. Consumers Energy website
3. Consumers Energy flyer or other marketing material
4. Friend, family, neighbor, or colleague
5. Email from Consumers Energy
6. Online search
7. Other (please specify)

98. Don't know

B7. What were the main reason(s) you decided to install a heat pump in your home? (Select up to three) **[RANDOMIZE 1–9]**

1. To reduce energy bills in the winter months
2. To reduce energy bills in the summer months
3. To distribute heating and cooling more evenly throughout the home
4. To add heating and/or cooling for a new or renovated space in the home
5. To replace a broken heating or cooling system
6. To reduce reliance on natural gas or delivered fuels
7. To add cooling (where there was not previously a whole-home system)
8. To take advantage of heat pump incentives (from Consumers Energy and/or my contractor)
9. To take advantage of electricity produced at my home by renewable sources (such as solar or wind)
10. Something else (please describe)

B8. Please rate the importance of the following items on your decision to install a heat pump. **[RANDOMIZE ITEMS]**

Items	Not at All Important 1	2	3	4	5	6	7	8	9	Extremely Important 10	Don't know
a. The amount of rebate from Consumers Energy (up to $1,000)	○	○	○	○	○	○	○	○	○	○	○
b. Recommendation from a contractor	○	○	○	○	○	○	○	○	○	○	○
c. Possible energy savings over the previous heating/cooling system	○	○	○	○	○	○	○	○	○	○	○

B9. Would you have installed a heat pump if Consumers Energy had not offered a heat pump rebate?
1. Yes (I would have installed a heat pump without a rebate)
2. No
98. Don't know

B10. **[IF B9>1]** Would you have installed a heat pump if the rebate had been one-quarter of the value you received (up to $250)?
1. Yes (I would have installed the heat pump with a $250 rebate)
2. No
98. Don't know

B11. **[IF B9>1]** Would you have installed a heat pump if the rebate had been half as much as the amount you received (up to $500)?
1. Yes (I would have installed the heat pump with a $500 rebate)
2. No
98. Don't know

C. *Thermostat Use*

Next, we have a few questions about how you typically use your thermostat to manage the level of comfort in your home.

C1. What type of thermostat do you have in your home? (Select one.)
1. **Non-programmable** thermostat (set temperature manually and it did not change automatically)
2. **Programmable** thermostat with **set-backs programmed** (thermostat set to automatically change temperature at specific times)
3. **Programmable** thermostat—**not programmed** (thermostat has programming capability, but these were not used.)
4. **Basic networked or Wi-Fi–enabled** thermostat (had remote control, but not occupancy sensing or learning features)
5. **Smart learning** thermostat that includes advanced features such as occupancy sensing and schedule learning (examples include Nest, Ecobee, Honeywell Lyric, and Emerson Sensi)
98. Don't know

C2. Who in your household tends to monitor and adjust your thermostat?
1. I mostly monitor and adjust my home thermostat
2. Everyone in my household monitors and adjusts my home thermostat
3. Other members of my household typically monitor and adjust my home thermostat

C3. How did your household **most frequently** manage your thermostat to control the temperature in your home this summer? (Select one)
1. Keep it at a constant temperature
2. Manually adjust the temperature as needed
3. Create customized/programmed settings to automatically change temperatures at different times of the day
4. Allow the smart thermostat to manage the temperature by learning my preferences and/or detecting when home or away
5. Other (please describe)
98. Don't know

C4. Your heat pump offers the ability to use heating and cooling schedules. Did the installation technician setup your heat pump on a heating and cooling schedule?
1. Yes, the installer set up a heating and cooling schedule
2. No, the installer did not set up a heating and cooling schedule
98. Don't know

C5. **[IF C4=1]** Are you still using this heating and cooling schedule?
1. Yes, I have kept the heating and cooling schedule
2. No, I (or someone in my household) turned off the heating and cooling schedule
3. No, I (or someone in my household) changed the heating and cooling schedule to my own
98. Don't know

C6. Have you been provided with instructions on how to set up and control your heating and cooling schedule on your heat pump?
1. Yes, I received instructions
2. No, I did not receive instructions
98. Don't know

D. *Installation and Usage Experience*

Next, we would like to know about your experience with the heat pump.

D1. Our records indicate that the heat pump was installed in your home around **[INSTALLATION-COMPLETE DATE]**. Were you present during the installation of the heat pump?
1. Yes
2. No

CADMUS

D2. Using a rating scale from 1 to 10, where 1 is *unacceptable* and 10 is *outstanding*, how would you rate each of the following installation experiences with the heat pump offering?

Question	Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know / NA
Scheduling a time for installation	O	O	O	O	O	O	O	O	O	O	O
Staying informed about the installation	O	O	O	O	O	O	O	O	O	O	O
[If D1=1] Overall installation time	O	O	O	O	O	O	O	O	O	O	O
[If D1=1] The professionalism of the installation technician	O	O	O	O	O	O	O	O	O	O	O
Education and instructions provided to you about heat pump usage	O	O	O	O	O	O	O	O	O	O	O
Follow-up from the installation technician or Consumers Energy	O	O	O	O	O	O	O	O	O	O	O

D3. **[IF ANY QUESTION IN D2=6 OR LOWER]** If there was something unsatisfactory about the heat pump installation, please describe in detail why you gave that rating.

_____

D4. In general, how did the heat pump affect your home comfort? (Select all that apply)

1. My home is **just as comfortable** as it was previously
2. My home is **more comfortable** than it usually was
3. My home is uncomfortably warm
4. My home is uncomfortably cold
5. My home is **too humid**
6. My home is **too dry**
7. My home was more evenly heated and/or cooled prior to the installation
8. Something else (please describe)

D5. **[IF D1=1 AND COMPLETE DATE IS PRIOR TO APRIL 1, 2021]** How would you rate the heating comfort level provided by the heat pump during winter months?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
O	O	O	O	O	O	O	O	O	O	O

[If D5<6] What concerns do you have about the heat pump's ability to heat to your comfort level?

_____

D6. How would you rate the cooling comfort level provided by the heat pump during summer months?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
O	O	O	O	O	O	O	O	O	O	O

[If D7<6] What concerns do you have about the heat pump's ability to cool to your comfort level?

_____

D7. Taking everything into consideration, how would you rate your overall experience with the heat pump so far?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
O	O	O	O	O	O	O	O	O	O	O

D8. Based on your experiences with the heat pump so far, how likely would you be to recommend it to a friend?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
O	O	O	O	O	O	O	O	O	O	O	O

D9. Based on your experience so far, do you have any recommendations to improve the heat pump rebate offer? _____

98. Don't know

D10. Since the heat pump was installed, have you seen a lower-than-expected energy bill?

1. Yes
2. No
3. Too soon to tell
98. Don't know

D11. In addition to energy savings, if any, are there additional benefits you have experienced or observed from the installation of a heat pump? (Select all that apply) **[RANDOMIZE]**

1. Increased comfort
2. Lower utility bills
3. Improved appearance of my home
4. Improved air quality
5. Improved heating and cooling distribution (across sections of my home)
6. Less maintenance required

7. Improved ability to manage heating/cooling on a schedule
8. Fewer illnesses for household members
9. Other (please specify)
10. Too soon to know **[EXCLUSIVE OF OTHER RESPONSES]**
11. No other benefits **[EXCLUSIVE OF OTHER RESPONSES]**

98. Don't know **[EXCLUSIVE OF OTHER RESPONSES]**

D12. **[If D12=1 AND D11<10]** Considering that the heat pump offering provided both saved energy and some additional benefits to your home, please indicate which was the most important to you:

1. The energy savings
2. The other benefits previously identified
3. The energy savings are equal to the other benefits

98. Don't know

E. *Demographics*

Finally, we have a few questions about your home.

E1. How many people live in your household on a regular basis, year-round?

1. 1
2. 2
3. 3
4. 4
5. 5
6. More than 5

99. Prefer not to answer

E2. Approximately how many square feet of living space does your home have? Do not include the basement unless it is a space that you consider lived in.

1. Under 1,000 square feet
2. 1,000 to less than 1,500 square feet
3. 1,500 to less than 2,000 square feet
4. 2,000 to less than 2,500 square feet
5. 2,500 to less than 3,000 square feet
6. 3,000 to less than 4,000 square feet
7. 4,000 or more square feet

98. Don't know

CADMUS

F. *Closing*

F1. On occasion, managers of the Consumers Energy programs may want to contact a customer to learn more about their participation experience. Please check here if you prefer not to be contacted by a program manager.
1. Do not contact me

F2. Do you have any recommendations for ways Consumers Energy can support you in helping you save energy?
1. Please describe_____

F3. To thank you for your time spent completing this survey, we would like to send you a $15 gift card to either Meijer or Amazon.com. Please choose which gift card you would like to receive.
1. $15 Meijer gift card
2. $15 Amazon.com gift card
3. Neither – I do not wish to receive a gift card

F4. **[IF F3=1 OR 2]** Please provide your name, address, and email to receive your gift card. This information will only be used to mail your gift card.
1. Name:_____
2. Address:_____
3. Address 2:_____
4. City:_____
5. State:_____
6. Zip:_____
7. Email**:** _____

Please click Next to submit the survey.

[END OF SURVEY MESSAGE] Those are all the questions we have at this time. Thank you for your participation in the Consumers Energy heat pump offer.

For more information on energy efficiency, here's where to find it:

- **Want Online Information about Our Other Energy-Efficiency Rebates and Programs?** For details of additional ways Consumers Energy may be able to help you make your home more energy efficient and help you manage your monthly energy bills, please visit us online at ConsumersEnergy.com/myhome.
- **Want to Speak to an Energy-Efficiency Advisor by Phone?** To talk to someone about additional rebates and programs, please contact one of our Energy Advisors at (888) 652-1237.

Appendix D. Consumers Energy Heat Pump Property Owner and Manager Interview Guide

Research Questions

Objectives	Research Questions	Interview Section
Document participant installation experience	How well did the offering manage the user installation experience? Are there opportunities to improve the installation experience?	B1, B3
Document participant usage behavior and experience	How are tenants using and operating the heat pumps? Did customers retain secondary or supplemental heating equipment after the heat pump was installed?	B2, B4
Document awareness and perceptions of heat pumps	What is the current perception of heat pump technologies? Were participants aware of heat pumps prior to being approached by Consumers Energy or the contractor? What are the perceived energy benefits of heat pumps? What non-energy benefits did the offering generate (such as reduced bill impacts, enhanced comfort levels, or improved operational issues)?	C1–C4, E2–E5
Document participant decision-making around participating in the heat pump offering	What key factors affected participants' decisions to install a heat pump? What are the key barriers to adopting heat pumps?	D1–D4
Identify marketing and outreach best practices	How did the participant learn about the offering?	C3
	What are the most effective means of marketing heat pumps?	F1–F3
Assess satisfaction with the offering and with Consumers Energy	How satisfied are property owners and managers with the heat pump offering? How satisfied are tenants with the heat pumps and the offering? How satisfied are property owners and managers with Consumers Energy?	G1–G4

Target Audience: The target audience for these interviews was multifamily PMOs who participated in the CCHP initiatives. The Evaluation team attempted to interview a census of participating PMOs.

A. General Introduction

A1. To begin, please tell me about your multifamily properties.

1. How many unique multifamily properties do you own or manage?
2. How many of them are located in Michigan?
3. Do you own/manage only subsidized or income eligible housing or do you also own/manage market rate properties?

B. Installation and Usage Experience

B1. Please describe your experience, including any positive or negative elements, of the heat pump installation for each of the following installation components (please note if you are not aware of any of these elements):

1. Scheduling a time for the installation
2. Informing the tenants
3. Overall installation time
4. Professionalism of the installation technicians
5. Education and instructions provided to management about heat pump usage
6. Education and instructions provided to tenants about heat pump usage **[PROBE: WERE YOU INFORMED ABOUT PRIORITIZING HEAT PUMP USAGE OVER BASEBOARD HEATING?]**
7. Follow up

B2. Have you received any feedback from your tenants about the new heat pumps? **[PROBE: DO THE COMMENTS TEND TO BE POSITIVE, COMPLAINTS, OR QUESTIONS?]**

B3. Have you had any concerns or issues with the heat pumps installed in your property? **[PROBE: HAVE TENANTS COMPLAINED, DO MAINTENANCE STAFF HAVE ANY FEEDBACK ABOUT THEM?]**

B4. It is our understanding that the existing baseboard heating equipment was left in tenant apartments. Are you aware of whether tenants are continuing to use their baseboard heaters or if they rely mostly on the new heat pumps for heating?

1. Are you aware if the tenants received educational materials or training on the use of the heat pumps? **[PROBE: HAVE TENANTS SEEN THESE MATERIALS? HOW WERE THEY DISTRIBUTED? DO THEY FIND THE MATERIALS TO BE USEFUL?]**

C. Heat Pump Awareness and Perceptions

C1. Before participating in this heat pump offering, were you familiar with heat pumps?

C2. Prior to participating in this offering, had you ever had a contractor recommend heat pumps?

C3. Before you participated in this offering, were you aware that Consumers Energy offered rebates for heat pumps?

1. **[IF HEARD ABOUT OFFERING]** Where did you hear about the heat pump offering?
2. **[IF HEARD ABOUT OFFERING]** What were your immediate perceptions of the offering?

C4. Other than **[NAME OF PROPERTY IN THE HEAT PUMP OFFERING]**, do any of your properties currently have heat pumps installed for heating and cooling?

1. **[IF HAS HEAT PUMPS INSTALLED]** How many (if any) of the properties you own/manage use heat pumps? **[PROBE TO SEE IF THEY ARE IN MICHIGAN]**
2. For those properties, do residents typically retain secondary or supplemental heating equipment after the heat pump is installed? Please describe.

D. Motivators and Barriers

D1. What were the most important factors in your decision to participate in the heat pump offering? **[DO NOT READ OR PROMPT; SELECT ANY THAT ARE MENTIONED]**

1. Lower tenant utility costs
2. Lower owner utility costs
3. Improve the property appearance
4. Improve tenant comfort
5. Increase the property value
6. Replace old or broken equipment
7. Take advantage of low-cost/no-cost improvements
8. Reduce impact on the environment
9. Lower operating and maintenance costs
10. Improve property aesthetics
11. Improve health and safety
12. Satisfaction with previous Consumers Energy program experience
13. Turnkey and easy to participate
14. Other (Please specify)

98. Don't know

D2. Which of these factors was the most important to your decision? **[REPEAT THOSE MENTIONED IN PREVIOUS QUESTION TO ALLOW SELECTION FROM LIST]**

D3. What do you consider to be the primary barriers to adding heat pumps to other properties? **[DO NOT READ OR PROMPT; SELECT ANY THAT ARE MENTIONED]**

1. Overall upfront costs
2. Logistical effort required to deal with installation
3. Finding the right contractor
4. Getting management approval
5. Tenant disruption
6. Tenants' ability to use the equipment to reduce energy consumption
7. Other (Please specify)

98. Don't know

D4. Which of these factors is the most significant barrier to your decision? **[REPEAT THOSE MENTIONED IN PREVIOUS QUESTION TO ALLOW SELECTION FROM LIST]**

E. Savings and Benefits of Participation

E1. Do you or your tenants pay the electric utility bills?

E2. **[IF TENANTS PAY]** Have your tenants provided feedback about their bills since installation of the heat pumps? If so, please describe what this feedback has entailed.

E3. **[IF PROPERTY OWNER/MANAGER PAYS UTILITY BILLS]** Have you noticed any change in your utility bills since installation of the heat pumps? If so, please describe the change. **[PROBE: HAVE THERE BEEN ANY DIFFERENCES IN UTILITY BILL CHANGES BETWEEN WINTER HEATING AND SUMMER COOLING?]**

E4. In addition to energy savings, are there any other benefits that your property, your tenants, or property management have experienced from installing the heat pumps? **[DO NOT READ OR PROMPT; SELECT ANY THAT ARE MENTIONED]**

1. Lower maintenance costs
2. Improved operations
3. Increased property value
4. Decreased vacancy rates
5. Increased rental income
6. Increased net operating income
7. Increased tenant comfort
8. Decreased late or nonpayment of rent
9. Decreased tenant complaints
10. Improved property aesthetics
11. Health and safety improvements
12. Other (Please specify)
13. Too soon to tell
14. No other benefits

98. Don't know

E5. **[ASK IF E3=YES AND E4≠13, 14, OR 98]** Considering that the heat pump offering provided both energy savings and some other benefits to your property, please indicate which was the <u>most important</u> benefit:

1. The energy savings
2. The non-energy benefits (previously identified)
3. The energy savings benefits are equal to the non-energy benefits

98. Don't know

F. Outreach and Marketing

F1. What, in your opinion, could be done to increase the adoption of heat pumps in the multifamily market?

F2. What are the most effective ways to let other multifamily property owners and managers know about the benefits of heat pumps?

F3. What information would be helpful for other property managers and owners to become interested in heat pumps?

CADMUS

G. Opinion of Heat Pump Offering and Consumers Energy

G1. Taking everything into consideration, how would you rate your overall experience with the multifamily heat pump offering, where 1 means *unacceptable* and 10 means *outstanding*?

Unacceptable 1	2	3	4	Average 5	6	7	8	9	Outstanding 10	Don't know
○	○	○	○	○	○	○	○	○	○	○

G2. Based on your experiences with the heat pump offering, how likely would you be to recommend the offering to a business colleague, where 1 means *extremely unlikely* and 10 means *extremely likely*?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

G3. Based on your experiences with the heat pump offering, how likely would you be to recommend Consumers Energy to a business colleague if you had a choice in energy providers, where 1 means *extremely unlikely* and 10 means *extremely likely*?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

G4. Based on your experience with the heat pump offering, how likely would you be to make similar improvements to some or all the properties you manage, where 1 means *extremely unlikely* and 10 means *extremely likely*?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

H. Wrap Up

H1. In what ways can Consumers Energy programs better help you manage your multifamily properties' energy use?

H2. Our research also includes a tenant survey to capture their experience and usage with the heat pumps, but we do not have tenant contact information to recruit them for this effort. Would you be interested in **[OPTION A]** securely sharing tenant emails with us so they can receive an email link to complete an online survey or **[OPTION B]** would you be willing to forward an email invitation to your tenants to complete the online survey? Tenants will receive a $15 gift card for their time. [**ENTER WILLINGNESS RESPONSE OPTION AND BE SURE TO REQUEST THE PMO EMAIL ADDRESS TO ENSURE EITHER OPTION CAN BE SHARED**]

Those are all the questions we have. Thank you very much for taking the time to assist us with this evaluation. Your contribution is a very important part of the process. We are planning to send you your choice of a $50 Amazon or Meijer card (if you choose Meijer, we will need your mailing address, as there is no e-card option). Please let us know your choice of card **[ENTER CARD CHOICE AND REQUEST EMAIL ADDRESS IF AMAZON OR MAILING ADDRESS IF MEIJER]**.

Look for your gift card in the mail in the next three weeks. If you have any questions about this survey or about your gift card, please call **[APEX STAFF]** at **[303-590-9888 Ext XXX]**. Thank you for your time.

CADMUS

Appendix E. Consumers Energy Heat Pump Multifamily Tenant Survey Guide

Objectives	Research Questions	Question Number
Document participant awareness of heat pump	Are tenants aware of what a heat pump is? Were tenants aware of a heat pump installed for their apartment? Are tenants who were aware of the heat pump also aware that Consumers Energy funded it?	Section B
Document participant installation experience	How did the heat pump offering help Consumers Energy to manage the tenant installation experience? Are there opportunities to improve the installation experience?	D1–C3
Assess participant perceptions of heat pump impact on comfort levels and electricity bills	What perceptions do tenants have of heating and cooling comfort levels? What are the perceived energy benefits of heat pumps? What non-energy benefits did the offering generate (such as reduced bill impacts, enhanced comfort levels, and improved operational issues)?	C4–C11, D2–D4
Document participant usage behavior and experience	How are tenants using and operating the heat pumps? Are tenants continuing to use their baseboard heating?	C12–C18
Assess participant satisfaction with the offering and with Consumers Energy	How satisfied are tenants with the heat pumps offering? How satisfied are tenants with Consumers Energy?	E1–G3, A1, A2

Survey Overview: The Evaluation team administered a web-based survey with multifamily tenants who received a new heat pump. Then the team sent an email with a link to the survey to participants who could be matched to participating multifamily buildings and had an email address, followed by reminder emails to encourage households to complete the survey within the desired timeframe. In addition, the Evaluation team offered participants a $15 Meijer or Amazon.com gift card for completing the survey.

Target Audience: Census of individual tenant dwellings that could be matched to the multifamily building and had an email address. The Evaluation team had 75 emails associated with the multifamily properties by linking an income-qualified survey contact database with the Income Qualified Multifamily incentive properties. Assuming a 10% response rate, we hoped to receive approximately eight completed surveys.

CADMUS

A. Current Company Metrics

First, we'd like to ask some questions about your opinions toward Consumers Energy.

Consumers Energy Count on Us®

A1. How likely would you be to recommend Consumers Energy to a friend or family member if you had a choice in energy providers?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
O	O	O	O	O	O	O	O	O	O	O	O

A2. Please describe in detail why you gave that rating. _____

B. Awareness

B1. Are you familiar with what a heat pump is?

1. Yes, I am familiar
2. No, I do not know what a heat pump is

[IF B1=2, PROVIDE EXPLANATION ABOUT HEAT PUMPS: HEAT PUMPS ARE EQUIPMENT THAT PROVIDES BOTH HEATING AND COOLING FOR HOMES.]

B2. Our records indicate that the apartment you currently occupy received a new heat pump. Are you aware of this?

1. Yes
2. No

B3. **[If B2=1]** Were you aware that Consumers Energy funded this project and made the heat pump technology available in your home?

1. Yes, I was aware of Consumers Energy involvement
2. No, I was unaware of Consumers Energy involvement
98. Don't know

CADMUS

C. Installation and Usage Experience

Next, we would like to know about your experience with the heat pump.

[SHOW QUESTIONS D1 TO C3 IF COMPLETE DATE IS NOT EMPTY]

C1. Our records indicate that the heat pump was installed in your apartment around **[COMPLETE DATE]**. Were you present during the installation of the heat pump?

1. Yes, I was present during installation
2. No, I was not present during installation

C2. Using a rating scale from 1 to 10, where 1 is *unacceptable* and 10 is *outstanding*, how would you rate each of the following installation experiences with the heat pump offering?

Question	Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
Scheduling a time for installation	○	○	○	○	○	○	○	○	○	○	○
Staying informed about the installation	○	○	○	○	○	○	○	○	○	○	○
[IF C1=1] Overall installation time	○	○	○	○	○	○	○	○	○	○	○
[IF C1=1] The professionalism of the installation technician	○	○	○	○	○	○	○	○	○	○	○
Education and instructions provided about heat pump usage	○	○	○	○	○	○	○	○	○	○	○
Follow-up from the installation technician or Consumers Energy	○	○	○	○	○	○	○	○	○	○	○

C3. **[IF ANY QUESTION IN C2≥6]** If there was something unsatisfactory about the heat pump installation, please describe in detail why you gave that rating.

_____

C4. Approximately how long have you lived in your current apartment?

1. Less than six months
2. Between six months and one year
3. Over one year

C5. Were you living in your apartment last winter, before the heat pump was installed?

1. Yes
2. No

C6. **[IF C5=1]** How would you rate the heating comfort level provided by the heat pump during winter months?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
○	○	○	○	○	○	○	○	○	○	○

C7. **[IF C6<7]** What concerns do you have about the heat pump's ability to heat to your comfort level? _____

C8. Were you living in your apartment last summer, before the heat pump was installed?

1. Yes
2. No

C9. **[IF C8=1]** How would you rate the cooling comfort level provided by the heat pump during summer months?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
○	○	○	○	○	○	○	○	○	○	○

C10. **[IF C9<7]** What concerns do you have about the heat pump's ability to cool to your comfort level? _____

C11. In general, how did the heat pump affect your home comfort? (Select all that apply)

1. My home is **just as comfortable** as it was previously
2. My home is **more comfortable** than it usually was
3. My home is uncomfortably warm
4. My home is uncomfortably cold
5. My home is **too humid**
6. My home is **too dry**
7. My home was more evenly heated and/or cooled prior to the installation
8. Something else (please describe)

C12. Our records indicate that the existing baseboard heating equipment was left in all apartments where heat pumps were installed.
Which of the following best describes how you heated your apartment last winter?
[RANDOMIZE 1-3]

1. Mostly used baseboard heating
2. Relied evenly on the heat pump and baseboard heating
3. Mostly used the new heat pump

98. Don't know

C13. Your baseboard heating should have a thermostat that controls your home's heating.
What type of thermostat do you have in your home?

1. **Non-programmable** thermostat (set temperature manually and it did not change automatically)
2. **Programmable** thermostat with **set-backs programmed** (thermostat set to automatically change temperature at specific times)
3. **Programmable** thermostat—**not programmed** (thermostat has programming capability, but these were not used.)
4. **Basic networked or Wi-Fi–enabled** thermostat (had remote control, but not occupancy sensing or learning features)
5. **Smart learning** thermostat that includes advanced features such as occupancy sensing and schedule learning (examples include Nest, Ecobee, Honeywell Lyric, and Emerson Sensi)

98. Don't know

C14. Who in your household tends to monitor and adjust your thermostat associated with your baseboard heating?

1. I mostly monitor and adjust my home baseboard thermostat
2. Everyone in my household monitors and adjusts my home baseboard thermostat
3. Members of my household (other than me) typically monitor and adjust my home baseboard thermostat

C15. How did your household **most frequently** manage your baseboard thermostat to control the temperature in your home this summer?
1. Keep it at a constant temperature
2. Manually adjust the temperature as needed
3. Create customized/programmed settings to automatically change temperatures at different times of the day
4. Allow the smart thermostat to manage the temperature by learning my preferences and/or detecting when home or away
5. Other (please describe)
98. Don't know

C16. Your heat pump offers the ability to use heating and cooling schedules. Did the installation technician set up your heat pump on a heating and cooling schedule?
1. Yes, the installer set up a heating and cooling schedule
2. No, the installer did not set up a heating and cooling schedule
98. Don't know

C17. **[IF C16=1]** Are you still using this heating and cooling schedule?
1. Yes, I have kept the heating and cooling schedule
2. No, I (or someone in my household) turned off the heating and cooling schedule
3. No, I (or someone in my household) changed the heating and cooling schedule to my own
98. Don't know

C18. Have you been provided with instructions on how to set up and control your heating and cooling schedule on your heat pump?
1. Yes, I received instructions
2. No, I did not receive instructions
98. Don't know

D. Savings and Benefits of Participation

D1. How would you describe how your electric utility use is billed?
1. I receive a monthly electric utility bill directly from the utility for my usage
2. My landlord receives an electric utility bill for the whole building's usage
3. The electricity use for my unit is billed some other way (please describe)
4. I'm not sure how the electric utility use is billed

D2. **[IF E1=1]** Have you seen a lower-than-expected energy bill?
1. Yes
2. No
3. Too soon to tell
98. Don't know

D3. In addition to energy savings, if any, are there other benefits that you have experienced or observed from the installation of heat pumps? (Select all that apply) **[RANDOMIZE 1–8]**

1. Increased comfort
2. Lower utility bills
3. Decreased complaints about my apartment temperature
4. Improved air quality
5. Improved appearance of my apartment
6. Improved heating and cooling distribution (across sections of my home)
7. Fewer illnesses for household members
8. Improved ability to manage heating/cooling on a schedule
9. Other (Please specify)
10. Too soon to tell [EXCLUSIVE OF OTHER RESPONSES]
11. No other benefits [EXCLUSIVE OF OTHER RESPONSES]

98. Don't know [EXCLUSIVE OF OTHER RESPONSES]

D4. **[ASK IF D2=1 AND D10≠10, 11, OR 98]** Considering that the heat pump offering provided both saved energy and some additional benefits to your apartment, please indicate which was <u>most important</u> to you:

1. The energy savings
2. The other benefits previously identified
3. The energy savings are equal to the other benefits

98. Don't know

E. Opinion of Heat Pump Offering and Consumers Energy

E1. Taking everything into consideration, how would you rate your overall experience with the heat pump?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
○	○	○	○	○	○	○	○	○	○	○

E2. Based on your experiences with the heat pump, how likely would you be to recommend a heat pump to a friend?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already Did Recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

E3. Do you have any recommendations for ways Consumers Energy can further support you in saving energy?
1. Please describe_____

F. Closing

F1. On occasion, managers of the Consumers Energy programs may want to contact a customer to learn more about their participation experience. **Please check here if you prefer not to be contacted by a program manager.**
1. Do not contact me

F2. To thank you for your time spent completing this survey, we would like to send you a $15 gift card to either Meijer or Amazon.com. Please choose which gift card you would like to receive.
1. $15 Meijer gift card
2. $15 Amazon.com gift card
3. Neither – I do not wish to receive a gift card

F3. **[ASK IF F2=1 OR 2]** Please provide your name, address, and email to receive your gift card. This information will only be used to mail your gift card.
1. Name:_____
2. Address:_____
3. Address 2:_____
4. City:_____
5. State:_____
6. Zip:_____
7. Email**:** _____

Please click Next to submit the survey.

Those are all the questions we have at this time. Thank you for your participation in the Consumers Energy heat pump offer.

For more information on energy efficiency, here's where to find it:

- **Want Online Information about Our Other Energy-Efficiency Rebates and Programs?** For details of additional ways Consumers Energy may be able to help you make your home more energy efficient and help you manage your monthly energy bills, please visit us online at ConsumersEnergy.com/myhome.
- **Want to Speak to an Energy-Efficiency Advisor by Phone?** To talk to someone about additional rebates and programs, please contact one of our Energy Advisors at (888) 652-1237.

CADMUS

Appendix F. Consumers Energy Heat Pump Commercial Interview Guide

Cold-Climate Heat Pump Participant Interview Research Objectives and Questions

Objectives	Research Questions	Interview Questions
Explore key factors in customer decision-making regarding heat pump installations	Were customers aware of heat pumps prior to the pilot outreach?	C1, C1a, C1b, C1c
	What were customers' perceptions of heat pumps prior to installation? What barriers did customers face when considering the installation of heat pumps?	C3
	What motivated customers to install heat pumps?	C5, C5a, C5b
	What technology would customers have installed without the initiative intervention and why?	C4, C4a
Explore customer experiences during the heat pump installation process	How did participants find their contractor who installed the equipment? How did participants perceive their contractors knowledge of heat pump technology and installation methods? How did participants perceive the length of time to purchase and install the heat pump and how long did that process take?	D1, D2, D4, D4a, D5
	What type of equipment did customers use prior to the heat pump? Did participants need to install new duct work, a new thermostat, and/or back-up systems for their heat pump?	D6, D7, D8, D9, D10
	Were participants satisfied with their contractors (including their interactions with their contractors and the contractors' performance), the installation process, and the timeline? Why or why not? Would they use the contractor again?	G1a, G1b, G1d, D3
Explore customer experiences using their heat pump	Does the heat pump provide the level of heating required for comfort and meeting customer needs?	E2, E2a
	Does the heat pump provide the level of cooling required for comfort and meeting customer needs?	E3, E3a
	Can customers operate the heat pump easily, including the remote controls? Do they need to change their habits in any way?	E1, E4, E4a, E5, E5a, E5b, E6
	How does the heat pump compare to prior equipment with regards to air quality?	E7, E7a
	How does the heat pump compare to prior equipment with regard to noise?	E8, E8a
	Are participants satisfied with their heat pump? Why or why not?	G1c
Explore customer experiences with the initiative offering	How did participants learn of the initiative opportunity?	C2
	Did participants interact with program staff? If so, what were their experiences?	F1, F1a, F1b
	Were participants satisfied with the pilot offering?	G1e
Identify opportunities to best support heat pump technology moving forward	Which aspects of the initiative offering were most helpful to customers (such as the staff support versus the financial incentive)?	F4
	What additional support, if any, did participants need to pursue the installation and use of their heat pump?	F2, F2a, F3, F3a, D4b

Survey Overview. The Evaluation team attempted to interview the full population of participating customers, with a goal to complete at least five interviews. The team included a $75 incentive to increase the likelihood of response. The Evaluation team sent advance emails to all respondents with available email addresses and followed up with phone calls as needed to schedule interviews. This email explained the research and provided a Consumers Energy and Evaluation team contact person if the respondent had additional questions or wanted to schedule an interview. For phone recruitment, the

team left a voicemail or receptionist message on the first attempt whenever possible, then used discretion to determine any additional messages left on subsequent attempts (with a maximum of five attempts to each contact).

A. Introduction

A1. First, can you tell about the work you do at **[BUSINESS NAME]**?

A2. And what is your role at the business? **[PROBE FOR ROLE AND RESPONSIBILITIES]**

B. Consumers Energy

Next, we'd like to ask you a few questions about your opinions toward Consumers Energy.

B1. How likely is it that you would recommend Consumers Energy to a friend or colleague if you had a choice in energy providers using a scale from 1 to 10, where 1 means *extremely unlikely* and 10 means *extremely likely*?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

B2. Please describe why you gave that rating.

B3. To what extent do you agree that Consumers Energy made it easy to participate in the Cold-Climate Heat Pump Initiatives, using a scale from 1 to 5, where 1 means *strongly disagree* and 5 means *strongly agree*?

Strongly disagree 1	2	3	4	Strongly agree 5
○	○	○	○	○

C. Decision-Making

Next, I'd like to ask some questions about your decision to install a heat pump.

C1. Prior to Consumers Energy contacting you about the heat pump offering, how familiar were you with heat pump technology to heat and cool your facility?

1. **[IF AWARE, PROBE]** What were your perceptions of heat pumps?
2. **[IF AWARE, PROBE]** Had you heard anything about their performance in colder climates?
3. **[IF KNOW ABOUT HEAT PUMP PERFORMANCE IN COLD CLIMATES]** Where did you hear about it?
4. **[IF AWARE, PROBE]** Had you heard anything about their performance in colder climates?

C2. How did you first learn of the opportunity to receive a heat pump through Consumers Energy?

C3. What key concerns or considerations did you have when deciding whether or not to install the heat pump?

C4. What motivated you to agree to install the heat pump?
1. Were there any other factors? **[PROBE FOR COST, ENERGY SAVINGS, ENERGY-EFFICIENCY, REBATE FROM CONSUMERS ENERGY]**

C5. Did you have plans to install new heating or cooling equipment if Consumers Energy hadn't reached out to you?
1. **[IF WOULD HAVE INSTALLED NEW HVAC EQUIPMENT]** When would you have installed this new equipment?
2. What steps would you have taken to decide what equipment to purchase?

D. Experience with Contractor Selection and Installation Process

The next set of questions are about your experiences finding a contractor and installing of your new heat pump.

D1. So, once you decided to participate in Consumers Energy's Cold-Climate Heat Pump offering, can you talk me through the steps you took to find and select a contractor to perform the work?

D2. Did you have any difficulties finding a contractor to perform the work?

D3. How knowledgeable were the contractors you worked with about heat pumps? What about the installation process? **[PROBE IF ANY DID NOT SEEM TO BE KNOWLEDGEABLE ABOUT THE EQUIPMENT, WHERE THEY WERE LACKING KNOWLEDGE]**

D4. Once you found a contractor, how long did the project take from start to finish (purchasing to installing)? Did this timeline meet your expectations?
1. **[IF TIME EXPECTATIONS NOT MET]** What were your expectations?
2. **[IF TIME EXPECTATIONS NOT MET]** Is there anything that could have been done differently? **[PROBE IF ANY PART OF THE PROCESS TOOK LONGER THAN EXPECTED]**

D5. If you had to do it over again, would you work with the same contractor?

D6. Prior to the installation, what type of heating equipment did you use? Did you use electric or natural gas or another type of fuel to heat the property?

D7. What type of cooling equipment did you use?

D8. Did your contractor need to install new duct work, a new thermostat, or other infrastructure as part of the heat pump installation?

D9. What did your contractor do with the old heating system? **[PROBE IF REMOVED, KEPT IN PLACE AS BACKUP, CAPPED]**

D10. Did you need to install a new back-up system along with the heat pump? **[PROBE FOR HEATING OR COOLING SYSTEMS]**

E. Experience Using the Heat Pump

Next, I'd like to ask some questions about your experiences using the heat pump itself.

E1. What have been your experiences with operating the equipment to date?

E2. Have you had a chance to use the heating function on the heat pump that was installed at your facility?
   1. **[IF USED HEATING]** What time of year did you use the heating function? Did you have any issues with the heat pump providing sufficient heat for your comfort and meeting your needs? **[PROBE FOR IF THEY EVER HAD ISSUES PROVIDING HEAT]**

E3. Have you used the cooling function?
   1. **[IF USED COOLING]** Did you have any issues with the heat pump providing sufficient cooling for comfort and meeting your needs?

E4. Does the heat pump require any new operating procedures that you needed to learn how to use?
   1. How did that go?

E5. Does the equipment rely on a remote control or app?
   1. Do you use that feature?
   2. How has that gone?

E6. Have you had to change your heating/cooling habits in any way to accommodate the new technology?

E7. Have you noticed any changes in air quality since the heat pump was installed? **[PROBE: DECREASED AIR PARTICLES, NOXIOUS GASES, DEBRIS]**
   1. **[IF YES]** How so?

E8. How does the sound of the new equipment compare to your old heating/cooling equipment?
   1. **[IF SOUND WORSE]** What have you done to deal with the noise, if anything?

F. Experience with Pilot Offering

Next, I have a few questions about your experiences with Consumers Energy in relation to this pilot and then we'll be almost done.

F1. Did you interact with Consumers Energy program staff at any point in the process?
   1. **[IF YES]** What did you discuss?
   2. Did you get your questions answered?

F2. What additional support, if any, did you need *when considering to purchase and install* your heat pump?
   1. Who did you talk to? What questions did you have?

F3. Did you require any additional support—other than what you received from Consumers Energy—during the *installation process*?
   1. What about when using the equipment?

F4. Thinking about all the aspects of the initiative, from the support you received in picking equipment or a contractor to the financial rebate for the project, what aspect was most helpful in your decision to pursue the heat pump installation?

G. Satisfaction

I'd like to wrap up the conversation by asking you to rate your satisfaction on a few different factors.

G1. Feel free to expand on any answers you provide. Each of these items will be on a 1 to 10 scale, where 1 means *unacceptable* and 10 means *outstanding*.

Question	Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know / NA
The installation your contractor performed	○	○	○	○	○	○	○	○	○	○	○
The time it took to receive and install your equipment	○	○	○	○	○	○	○	○	○	○	○
The performance of the heat pump equipment	○	○	○	○	○	○	○	○	○	○	○
The interactions you had with your contractor	○	○	○	○	○	○	○	○	○	○	○
The overall Consumers Energy offering	○	○	○	○	○	○	○	○	○	○	○

CADMUS

H. Closing

As we wrap up, I want to provide an opportunity for you to share anything I might have missed with my questions.

H1. Do you have any other comments or information you think might be useful for me to know given what we have talked about today?

H2. These are all the questions I have for you today. It is likely that one of our colleagues will be following up with you in a few months to better understand the energy use of your new cold-climate heat pumps during the winter months, so look out for that email or call. As a thank you for your input, we'd like to send you a $75 gift card redeemable at many businesses, including Amazon, Target, and Kroger. This gift card is called a Tango card and would be sent to your email address within the next five to 10 business days. Alternatively, we can donate the $75 to your local United Way. Which would you prefer?

H3. **[IF TANGO]** Could you please provide your preferred email address to receive the Tango virtual gift card? **[REPEAT BACK EMAIL ADDRESS]**
You should expect to receive your virtual gift card within the next five to 10 business days. The gift card will be emailed directly from **Tango,** with a reference to "Thank you for your participation!" If you have any questions, or have not received your gift card by then, please contact me at **[contact information]**.

H4. [IF UNITED WAY] In whose name should we make the donation to United Way? [INCLUDE FIRST AND LAST NAMES, COMPANY NAME, OR ANONYMOUS]
And what zip code should we use to find your local United Way?

On behalf of Consumers Energy, I want to thank you for taking time to provide input, and have a great day. **[END CALL]**

CADMUS

Appendix G. Consumers Energy Heat Pump Contractor Interview Guide

Introduction and Purpose

Thank you for taking the time to talk with us today. This interview is a discussion about air source cold climate heat pumps, your businesses experience with the technology, and to assess the current status of the technology in the market. The intended outcome of this discussion is to document the perception, concerns, opportunities, critical decision points, and key outcomes involved with heat pump sales and installations. Consumers Energy can use this documentation to guide future decision making around their energy efficiency programs. We are offering a $75 gift card that can be redeemed at your choice of Amazon or Meijer for those that complete the 30-45 minute interview. We have four main objectives for this interview:

- Identify current levels of awareness and perceptions of heat pump technologies.
- Identify the main barriers to installing heat pumps in Michigan and if the Michigan market is ready for widespread adoption of heat pump technology.
- Identify any marketing or outreach best practices
- Document awareness of available heat pump incentive offerings

We expect this interview to take around 30 minutes.

A. General Introduction

A1. To begin, tell me about your business.
   1. What types of customers do you typically serve? [Standard residential? Income qualified? Multi-family? Commercial? Something else?]
   2. How many projects do you typically complete in a given year?
   3. How many employees does your company have?

A2. What type of equipment do you typically install? [Furnaces? Boilers? Heat pumps? Something else?]

A3. Do you have any experience participating in utility energy efficiency programs?
   1. Which utilities? Which programs? How often?

B. Heat Pump Awareness and Perceptions

B1. Does your company sell and install heat pumps?

1. **[If installs heat pumps]** How many (if any) heat pump sales or installations have you/your company had in the past year (2020)?
2. For those installations, do residents typically retain secondary or supplemental heating equipment after the heat pump is installed? Please describe.
3. What heat pump brands do you carry and install?
   Have you received any manufacturer-specific certifications for installing those brands?
4. How does the average warranty of a CCHP compare to gas furnaces or boilers?
5. **[If does not install heat pumps]** Why don't you install heat pumps?

B2. Do you promote CCHPs to your customers?

1. Are there specific applications or customer types that make good candidates for heat pumps? (i.e. retrofit vs. new construction)
2. Which ones?
3. Why?
4. Are small businesses good candidates for heat pumps?
   Are the barriers to entry different than the residential homeowner?

B3. Generally, what are your perceptions of CCHPs?

1. Do you think that CCHPs are a viable option for widespread adoption in Michigan?
2. Do you think that CCHPs are capable of generating energy savings for end users?
3. What has led to those perceptions of the equipment?
4. What do you think is the value proposition for you to want to install heat pumps? Why would you not want to?
5. Do you know other contractors who install CCHPs? What are their perceptions of the technology?

B4. What are customer perceptions of heat pumps?

1. Do they typically have any awareness of the technology?
2. What do you think is the value proposition for customers to install a heat pump? What are their motivations? If needed: Why would they not want to?
3. Do customers ever request to have the equipment installed without being prompted by your company? How do you respond to that request?
4. Is customer interest in heat pumps increasing, decreasing, or staying about the same? What would you say is causing that change?

B5. To what extent does a negative experience with older heat pump technologies affect your opinion about heat pumps? What about customers experiences?

C. Market Barriers and Regulatory Readiness

C1. **[If installs heat pumps]** How do procedures for a heat pump installation compare to installing other HVAC equipment in terms of:
1. Time required (actual installation time).
2. Sales process/discussions with customers.
3. Revenue/Profit Margin.
4. Equipment availability.
5. What factors can cause variations in these procedures? (e.g. conversion vs. replacing similar equipment).

C2. What would you say are the main barriers or challenges preventing more widespread heat pump adoption in Michigan? [Probe for: customer awareness, contractor perceptions, equipment availability, codes and standards, energy prices, finding good candidates, etc.]

C3. If demand for heat pumps increases, how well do you think the supply chain is prepared to meet that demand (increasing production) for cold climate heat pumps? Why?
1. Do you have any concerns about the availability or delivery timing of heat pump equipment for current or future projects? Why or why not?

D. Outreach and Marketing

D1. What can Consumers Energy do to help drive adoption of heat pumps in the market?

D2. Do you think that messaging is needed to educate people that CCHPs, or heat pumps in general, have improved?
1. **[IF YES]** What would effective messaging look like?

D3. **[If Promotes heat pumps]** When you have a good candidate for a heat pump, what information is most convincing for the customer to install a heat pump?

E. Wrap Up

E1. Before we wrap up, is there anything else you'd like us to know?

Those are all the questions we have for you. Thank you very much for taking the time to assist us with this evaluation. Your contribution is a very important part of the process. Do you mind if we follow-up with you by phone or e-mail later, if additional questions arise?

E2. To thank you for your time spent completing this survey, we would like to send you a $75 gift card to either Meijer or Amazon.com. Please choose which gift card you would like to receive.
1. $75 Meijer gift card
2. $75 Amazon.com gift card
3. Neither – I do not wish to receive a gift card

E3. Please provide your name, address, and email to receive your gift card. This information will only be used to mail your gift card.

1. Name:_____
2. Address:_____
3. Address 2:_____
4. City:_____
5. State:_____
6. Zip:_____
7. Email**:** _____

You should receive your gift card within four weeks. If you have not received it by then, please contact (contact person at Cadmus).

CADMUS

Appendix H. Consumers Energy Heat Pump Manufacturer and Distributor Interview Guide

Research Objectives and Questions

Research Objectives	Research Questions	Interview Questions
Confirm/document the supply chain for CCHPs in Michigan	Do CCHPs follow the typical supply chain structure (Manufacturer -> Distributor -> Contractor -> Customer)?	EE1, EE2
	Does the supply chain vary for small commercial, multifamily, and residential end uses?	EE1
Identify the barriers leading to extended timelines for CCHP installation	How long does it typically take from manufacturing to distribution? Distribution to contractors?	FF1
	What caused delays in the timeline in 2020? Have there been any changes to this timeline due to COVID-19? Were delays different across states? Did demand for CCHP in Michigan differ in 2020 compared to 2019?	FF1, FF2, GG2
	Are any delays expected to improve in 2021?	FF1
Identify sources of differences in CCHP installation costs across states	Are wholesale costs in Michigan comparable to other states?	FF3
	What factors drive pricing of CCHPs?	FF3
Explore the cause of low participation by trade allies	What have manufacturers and distributors done to promote heat pump technology?	GG5, GG6
	What feedback have contractors (distributors) offered to distributors (manufacturers) on perceptions of CCHP?	GG3, GG4
Identify any additional barriers and challenges delaying widespread adoption of CCHPs in Michigan, like training or education	What are the primary barriers or challenges faced by manufacturers / distributors in selling and distributing CCHP?	GG1, G1
Identify ways in which Consumers Energy can influence market adoption	How can utilities best support the adoption of CCHPs? Where is the correct place to offer an incentive (downstream, midstream, or upstream)?	II1
	Are there successful market influences in other states that could be promoted in Michigan?	HH1
	Are there technology advancements that Consumers Energy should be aware of?	HH2

A. Firmographics

First, I have just a couple questions about your organization and your role. Please note that I will keep your individual responses anonymous.

A1. What is your role in the company?

A2. What areas of the country does your company primarily serve?

A3. **[DISTRIBUTORS]** Do you serve as a distributor of heat pumps in states other than Michigan? **[PROBE FOR DETAIL]**

A4. **[MANUFACTURERS]** Do you work with particular states/regions or nationwide? **[PROBE FOR DETAIL]**

B. Supply Chain

Now I have some questions about the supply chain for the cold-climate air-source heat pump market. If possible, I would like you to focus your responses on the market in the state of Michigan.

B1. How does heat pump equipment typically get from the manufacturer to the end-use customer?
   1. What are the key roles in the cold-climate heat pump market from production to installation (such as manufacturers, distributors, contractors, and electricians)?
   2. Does the supply chain for cold-climate heat pumps differ from traditional air-source heat pumps? What about other types of mechanical equipment (such as furnaces, boilers, or water heaters)? If so, how?
   3. Does the supply chain vary depending on the type of building where the unit will be installed (single family, multifamily, or small commercial building)?

B2. Are there particular distributors, manufacturers, or contractors you work with for cold-climate heat pumps in Michigan? **[PROBE FOR DETAIL]**

C. Timeline/Costs

Next, we would like to ask you some questions specifically surrounding production and distribution timelines and costs.

C1. On average, what would you say is the length of time it normally takes for a cold-climate heat pump to reach the distributor or contractor after an order is placed?
Does the timeframe in Michigan differ from other states?
   1. **[MANUFACTURERS]** When fulfilling orders for cold-climate heat pumps, what specific manufacturing challenges, if any, have you experienced in the Michigan market? **[PROBE FOR DETAIL]**
   2. How does this compare to other states?
   3. Did production times change from 2019 to 2020? If so, how? What do you attribute this to?
   4. What do you think production times will look like in 2021?
   5. **[DISTRIBUTORS]** Have you experienced any issues with the availability of cold-climate heat pumps in Michigan? **[PROBE FOR DETAIL]**
   6. How does this compare to other states?
   7. Did availability change from 2019 to 2020? If so, how? What do you attribute this to?
   8. What do you think availability will look like in 2021?
   9. Does the timeline for cold-climate heat pumps vary by season? If so, how?

C2. **[DISTRIBUTOR]** Do you typically stock cold-climate heat pumps or do you place orders after a purchase is made?
   1. How many units do you typically have on-hand? What types? Are NEEP specifications considered? What led to your decision to stock these units?
   2. **[IF NOT]** What prevents you from stocking cold-climate heat pumps?

C3. Compared to other states, are cold-climate heat pumps in Michigan competitively priced?

1. Have costs been stable over time?
   [PROBE] Have costs differed from 2019 to 2020?
   [PROBE] Do you think that change is temporary?
2. **[MANUFACTURERS]** Has there been much variation in cost of parts and labor in the manufacturing of the cold-climate heat pumps?
3. **[DISTRIBUTORS]** Has there been much variation in cost based on availability of cold-climate heat pumps?

D. Demand/Adoption

I would now like to spend a few minutes talking about overall interest for cold-climate heat pumps in the market.

D1. Compared to other states, how much demand is there for cold-climate heat pumps in Michigan?

1. What do you see as the primary barriers or challenges that are restricting widespread adoption of heat pump technology in Michigan?
2. How do warranties for cold-climate heat pumps compare to warranties for other technologies (such as natural gas furnaces)?

D2. In 2020, did demand for cold-climate heat pumps in Michigan differ from 2019?

1. **[IF YES]** What do you think caused that change?
2. Do you think the change was temporary or will it be resolved?
3. Have there been any impacts on demand related to COVID-19, that you are aware of?
   [PROBE FOR DETAIL]

D3. **[MANUFACTURERS]** What feedback have you received from distributors in Michigan about heat pump technology adoption?

1. What about cold-climate heat pumps, specifically?
2. Is this different from other states?

D4. **[DISTRIBUTORS]** What feedback have you received from contractors in Michigan about heat pump technology?

1. Is this different from other states?

D5. Do you know of any promotions or trainings your organization does to increase awareness of cold-climate heat pumps among your customers in Michigan?

1. Does this differ from other states?
2. Is this different from other types of equipment?

D6. Specifically, what has your organization done to promote heat pump technology to distributors/contractors?

1. Have you offered trainings, informational pamphlets, sales/discounts, or something similar?

E. Solutions

In this final section, I'd like to shift gears a little to understand your thoughts on how Consumers Energy and other utilities could provide support to further the adoption of cold-climate heat pump technology.

E1. Is there anything you think utilities could do to improve the adoption of cold-climate heat pump technology in Michigan? **[PROBE FOR DETAIL; SOLUTIONS BEYOND INCREASING INCENTIVES]**
   1. In your opinion, where is the right place to offer an incentive to drive adoption of a newer product such as cold-climate heat pumps (downstream, midstream, or upstream)?
   2. Have you seen models for promoting the adoption of cold-climate heat pumps in other jurisdictions that Consumers Energy should consider?

E2. Are there any recent or upcoming advancements in heat pump technology that Consumers Energy should be aware of?

F. Closing

As we wrap up, I want to provide an opportunity for you to share anything I might have missed with my questions.

F1. Do you have any other comments or information you think might be useful for me to know given what we have talked about today?

F2. These are all the questions I have. As a thank you for your input, we'd like to send you a $75 gift card to Amazon, Target, or Meijer. Amazon and Target gift cards are virtual and would be sent to your email address within the next 5 to 10 business days. Meijer is offered as a physical gift card, which will be mailed to your preferred address. Alternatively, we can donate the $75 to your local United Way. Which would you prefer?
   1. Amazon
   2. Target
   3. Meijer
   4. Please donate to my local United Way

F3. **[IF G2=1 OR 2]** Could you please provide your preferred email address to receive the **[AMAZON OR TARGET]** virtual gift card?

F4. **[IF G2=3]** Let me ask the information we need to mail your gift card to the intended recipient—this could be you personally or anyone else of your choosing:
   1. First name of recipient:
   2. Last name of recipient:
   3. Could you please provide the street address we should use to send the gift card?

You should expect to receive your gift card by no later than **[DATE]**. If you have any questions, or have not received your gift card by **[DATE]**, please contact **[contact information]** and reference the Consumers Energy heat pump interview.

F5. **[IF G2=4]** In whose name should we make the donation to United Way? **[INCLUDE FIRST AND LAST NAMES OR COMPANY NAME]**

On behalf of Consumers Energy, I want to thank you for taking time to provide input, and have a great day. **[TERMINATE]**

Across building types, single-family homes could be most likely to convert to hybrid ASHP, though there are obstacles to conversion

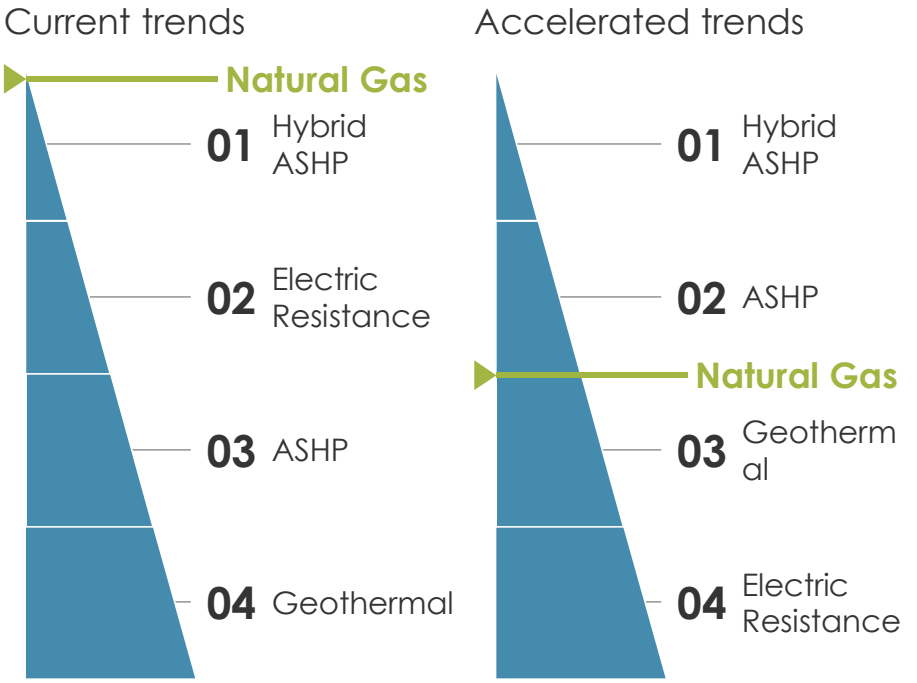
ILLUSTRATIVE ANALYSIS

Single-family homes – Urban

Considerations for converting away from natural gas space heating

- **Easier to convert**, due to less retrofit complexity
- **Individual decision-makers** (as compared to a co-op or HOA in a multi-unit building) enables more rapid decision-making to convert
- Lack of space may be a challenge, but **94% of single family homes are detached**, with more available space for heating appliances
- **Upfront cost of converting from natural gas to electric can be a deterrent** for many households
  - New gas furnace + installation: $ 4.500
  - New ASHP + installation: $12.000

Preferred technology based on trends assumptions



Compared to other building types, non-urban single-family homes may be able to more easily convert to geothermal space heating

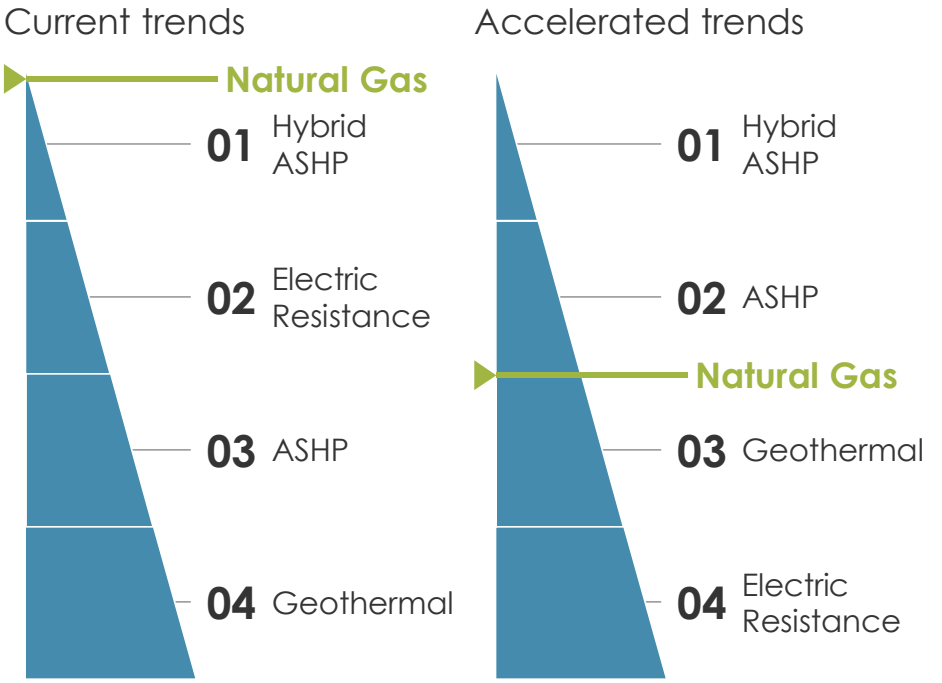
ILLUSTRATIVE ANALYSIS

Single-family homes – Non-urban

Considerations for converting away from natural gas space heating

- **Easier to convert**, due to less retrofit complexity
- **Available land** for technologies requiring more space
- **Individual decision-makers** (as compared to a co-op or HOA in a multi-unit building) enables more rapid decision-making to convert
- Located in least congestion areas, therefore **likely won't to require electric grid upgrade**
- **Upfront cost of converting from natural gas to electric can be a deterrent** for many households
  - New gas furnace + installation: $ 4.500
  - New ASHP + installation: $12.000

Preferred technology based on trends assumptions



Electrification is more challenging for multi-family home buildings compare to single-family homes due space constraints and stakeholder coordination

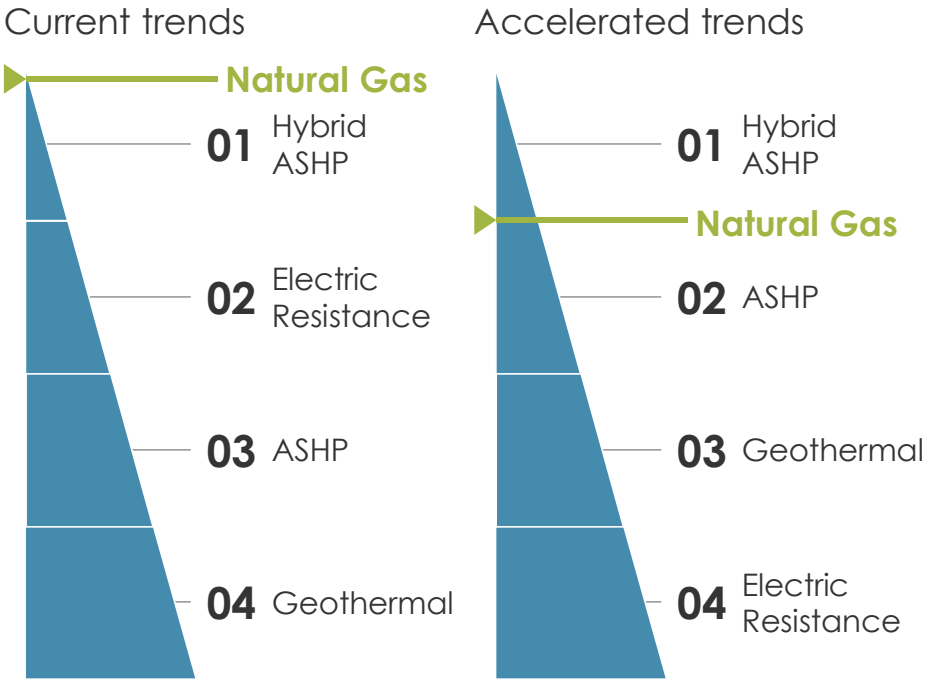
ILLUSTRATIVE ANALYSIS

Multi-family homes

Considerations for converting away from natural gas space heating

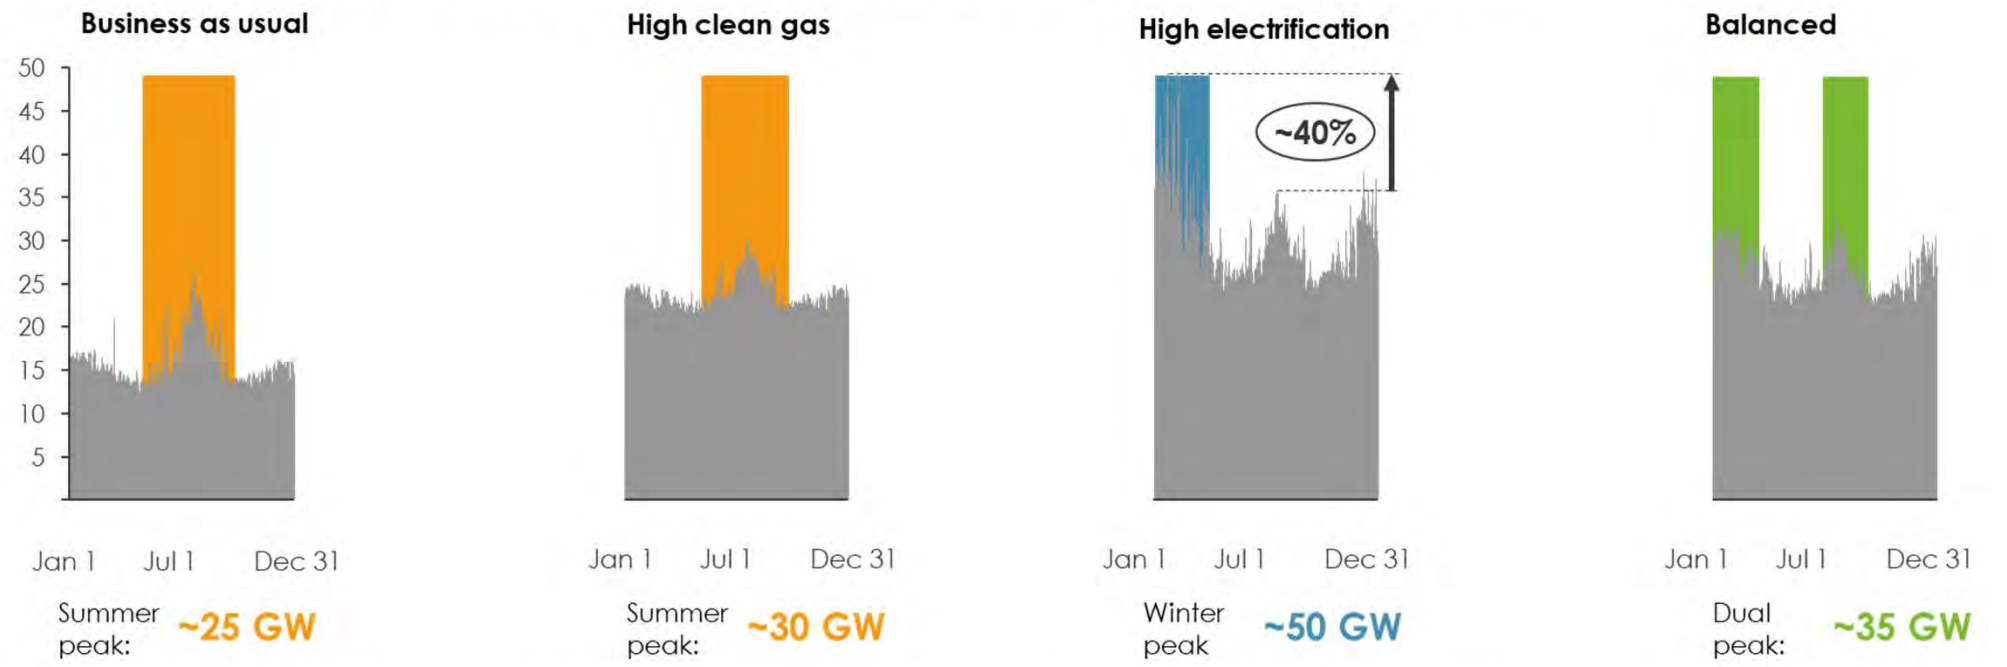
- Harder to convert, due to **complexity and costs associated with retrofit**
- **Lack of space** can make some technologies unfeasible
- **Collective decision** imposes additional challenge, as households with different preferences / willingness to invest, must agree upon technology
- Located in congestion areas, therefore **likely to require electric grid upgrade**

Preferred technology based on trends assumptions



Michigan Energy Load by Scenario

MI daily maximum electric load, from January 1 to December 31, 2050, GW

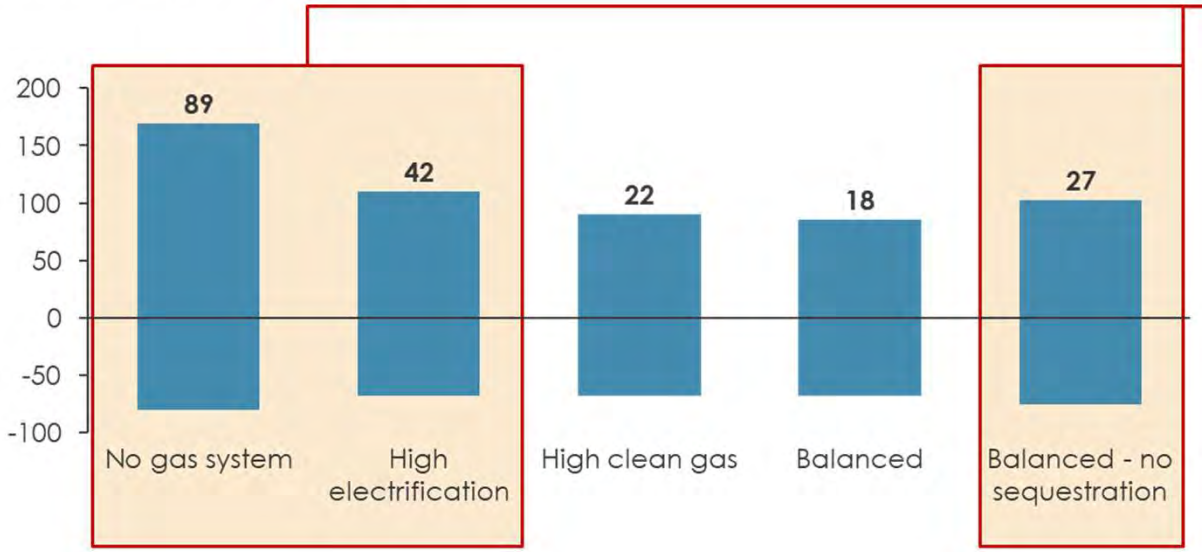


Winter peak with high electrification has significant cost implications due to additional electric T&D build out

Michigan Societal Cost Impact by Scenario

NPV of total system costs relative to reference case[1]

$B, 2020 – 2050, all of Michigan



Disallowing either the natural gas system or sequestration from the system results in **prohibitively expensive pathways**

1. **Gas distribution** enables cost effective heating
2. **Gas transmission is needed to supply gas to power plants that firm renewable power**
3. **Carbon sequestration** is needed to cost effectively negate emissions
4. Gas provides **system resiliency, diversification**, and energy for **hard-to-electrify end-uses**

1. Gas infrastructure costs based on high-level initial assessment. Granular data on Michigan-system pipeline inventory can be used to develop more detailed analyses

Renewable Energy and Electrification Infrastructure Enhancement and Development Grant

RESPONSE DOCUMENT

Bidder Name: Consumers Energy Company

ESTIMATED TIMELINE	
Issue Date	December 20, 2023
Inquiries Due (round one)	January 11, 2024
Reponses to Inquiries Posted	January 18, 2024
Inquiries Due (round two)	January 26, 2024
Responses to Inquiries Posted	February 5, 2024
Proposals Due	February 21, 2024
Proposals Posted Publicly	February 28, 2024
Public Comment Period End Date	April 12, 2024
Modified Proposals Due	April 29, 2024
Modified Proposals Posted Publicly	May 1, 2024
Anticipated Announcement of Grant Awards	September 2024
Anticipated Grant Start Date	November 15, 2024

PART III: WORK STATEMENT

III-A Purpose

The purpose of this Request for Proposals (RFP) is to obtain proposals from businesses, nonprofit organizations, local units of government, and tribal governments, for the purpose of planning, developing, designing, acquiring, or constructing renewable energy and electrification infrastructure projects. The MPSC may consider awarding up to 10% of the funding available to planning grants. The MPSC welcomes all technologies, project sizes, and locations to apply, consistent with the language outlined in Public Act 119 of 2023.

From the total amount of funding for grants awarded for electric vehicle fast-charging infrastructure, 25% of that total amount must be allocated for infrastructure that provides charging at a power level of 350 kilowatts or less and 75% of that total amount must be allocated for infrastructure that provides charging at a power level of more than 350 kilowatts.

NOTE: The MPSC reserves the right to award funds for an amount other than that requested and/or request changes to, or clarification of any and all proposals received as a result of this RFP.

III-B Problem Statement

This grant will support renewable energy and electrification infrastructure enhancement and development projects.

III-C Objectives

Prioritized infrastructure or planning projects funded hereunder will meet one or more of the MI Healthy Climate Plan goals, specifically to:

1. Commit to environmental justice and pursue a just transition
2. Clean the electric grid
3. Enable electric vehicle charging infrastructure and increase public transit
4. Repair and decarbonize homes and businesses
5. Drive clean innovation in industry
6. Protect Michigan's air, land, and water

III-D Tasks

The tasks outlined below must be included in an application for either a renewable energy and electrification facility or program (infrastructure) grant or a renewable energy and electrification planning grant.

A. Renewable Energy and Electrification Facilities or Program Infrastructure Grant applicant(s) must include the following to be considered for an award:

1. Submit an impact study of the project that includes an analysis of the following:
   a. Potential cost savings.
   b. Environmental impacts. In calculating the carbon emission reductions, a life cycle approach utilizing the Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) Model developed by Argonne National Laboratory is preferred. Emission must be expressed in terms CO2e (carbon dioxide equivalent).
   c. Local economic benefits.

   Note: A utility, at its sole discretion, may prepare a single impact study covering the utility's service territory that accounts for likely proposals, evaluates regional opportunities, and minimizes or eliminates the need for repetitive studies.

2. Submit details addressing how the proposed project will align with the governor's MI Healthy Climate Plan.
3. Submit a detailed project timeline and Gantt chart. The estimated grant start date is November 15, 2024. Projects must be completed by August 15, 2026 for the portion of the project being funded by the grant.

B. Renewable Natural Gas (RNG) Infrastructure Grant applicant(s) must include ALL of the following to be considered for an award:

"Renewable natural gas" or "RNG" means methane derived from organic material and degradable carbon sources, including, but not limited to, carbon sources and materials sourced from municipal solid waste, plant materials, or food waste. Renewable natural gas injected into a pipeline for downstream use must meet pipeline quality specifications.

1. Submit an impact study of the project that includes an analysis of the following:
   a. The project details, including the location of renewable natural gas and the proposed interconnection.
   b. The cost estimates for the interconnection, metering, and gas conditioning equipment needed to connect to an existing pipeline system.
   c. A summary of the environmental and health impacts of the project, including the forecasted emission reductions. In calculating the carbon emission reductions, a life cycle approach utilizing the Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) Model developed by Argonne National Laboratory is preferred. Emission must be expressed in terms CO2e (carbon dioxide equivalent).
   d. Any local economic impact from the RNG infrastructure development.
   e. The end-use application for the RNG infrastructure with a focus on projects being used for opportunities in this state.
2. Submit details addressing how the proposed project will align with the governor's MI Healthy Climate Plan.
3. Submit a detailed project timeline and Gantt chart. The estimated grant start date is November 15, 2024. Projects must be completed by August 15, 2026 for the portion of the project being funded by the grant.

C. Renewable Energy and Electrification Facilities or Program Planning Grant applicant(s) must include ALL of the following to be considered for an award:

1. Submit a narrative including all of the following information:
   a. Explanation of what planning will be taking place and how the grant award will be spent.
   b. Explanation of the future project(s) which the planning is being conducted for.
   c. Detailed Timeline and Gantt chart for the planning to be conducted and the future project being planned for. The estimated grant start date is November 15, 2024. Planning must be completed by August 15, 2026 for the portion of the project being funded by the grant.
   d. Potential impact to Michigan citizens and businesses, including how the planning grant applicant intends to engage affected or surrounding community members and stakeholders in planning and project design and/or implementation.
   e. How the future project(s) the planning is being conducted for will align with the governor's MI Healthy Climate Plan.

2. Identify potential funding sources to undertake construction of facilities or implementation of programs that a planning grant is being conducted for.

PART V: INFORMATION REQUIRED FROM APPLICANT(S)

Applicant(s) must submit one proposal. **Electronically submitted proposals must have a scanned signature or e-signature** and cannot exceed 15 MB.

Applicant(s) must provide responses to each section below. **The RFP Response Template document can be found on the Renewable Energy and Electrification Infrastructure Enhancement and Development Grant webpage.** Be as descriptive as possible and answer each question in its entirety; some questions have multiple components. In your responses, provide a straight-forward, concise description of the applicant(s)'s ability to meet the requirements of the RFP.

Questions that do not apply should be answered "N/A."

V-A Identification of Organization

Applicant will provide the following:

1. State the full name and address of the organization.
2. The organization's federal identification number.
3. The organization's telephone numbers.
4. What percentage of the organization is located in Michigan.
5. The organization's SIGMA ID number. Refer to Section I-B, Eligibility Requirements.
6. The organization's SIGMA ordering mail code Refer to Section I-B, Eligibility Requirements.
7. Name of the authorized signer(s) for any future grant agreements, their title, telephone number, fax number, and electronic mail address.

Bidder response:

1. Consumers Energy Company
   One Energy Plaza
   Jackson, MI 49201
2. Federal ID Number: 38-0442310
3. 800-477-5050
4. Company is 100% located in Michigan
5. SIGMA ID number, CV0018795
6. SIGMA Address Code: 008
7. Holly Bowers
   Vice President, Gas Engineering and Supply
   Phone: 517-740-3232
   Fax: 1-800-363-4806
   Email: holly.bowers@cmsenergy.com

V-B Authorized Negotiator

State the name of one (1) contact person and their title, telephone number, fax number, and electronic mail address. The contact person must be authorized to be the negotiator for the proposed Grant Agreement with the State of Michigan.

Bidder response:
Neal Dreisig
Sr. Strategy Manager
Phone: 989-239-8071
Fax: 1-800-363-4806
Email: neal.dreisig@cmsenergy.com

V-C Project Summary

Please provide a project summary not more than 500 characters in length.

Bidder response:
The proposed network geothermal Planning Project supports Public Act 119 of 2023 and objectives of the MI Healthy Climate Plan including environmental justice, decarbonizing homes and businesses, and clean innovation energy hubs. The Project seeks to site, configure, model and assess cost and benefits for a network geothermal system that best supports environmental justice, carbon reduction, energy efficiency, and energy cost savings.

V-D Method for Addressing the Problem

State in succinct terms how the applicant(s)'s proposed project will support renewable energy and electrification infrastructure enhancement and development. Refer to Section III-B, Problem Statement.

Bidder response:
The Planning Project is an electrification technology and infrastructure development project that will identify, assess and plan for the most cost effective and energy efficient location to electrify natural gas end uses using network geothermal system technologies that are mature and readily available today.

V-E Project Objectives

Explain how the applicant's infrastructure or planning project will meet the goals of the MI Healthy Climate Plan. Refer to Section III-C, Objectives. Also include any other identified project metrics that will be included in the project status reports as referenced in Section IV-B.

Bidder response:
The network geothermal Planning Project supports MI Healthy Climate Plan goals by reducing emissions related to heating Michigan homes and businesses 17 percent by 2030, and achieving economy-wide carbon neutrality by 2050. The MI Healthy Climate Plan says that "reaching our mid-century milestone will require particularly substantial effort and innovation in the sectors of our economy that are hardest to decarbonize, including industry, buildings and housing, and agriculture." Network geothermal uses mature technology innovatively to maximize energy efficiency and cost of energy in the most impacted regions.

1) **Commit to environmental justice and pursue a just transition**. With efficiencies up to 600%, network geothermal systems provide superior cost of energy savings and work best in regions with diverse energy loads and the patterns of those loads. Diverse load profiles makes low-

income neighborhoods often adjacent to industrial parks ideal for planning. Planning activities will assess these regions, using the Michigan Environmental Justice (MiEJ) screen, that best fit network geothermal system profiles. Additionally, planning activities support the Michigan State Housing Development Authority (MSHDA) 2022 Statewide Housing Plan goals, as described under "MI Healthy Climate Plan" section.

2) **Clean the electric grid.** The Planning Project will assess how network geothermal systems in specific locations mitigate seasonal peak electric loads and intermittency of renewable energy sources in an electrified future. With energy efficiencies upwards of 600%, network geothermal heating and cool capabilities could meaningfully mitigate increased costs associated with the buildout of electric infrastructure, therefore limiting the energy burden for cleaner electricity.

3) **Repair and Decarbonize homes and businesses.** The Planning Project directly supports eliminating emissions tied to the combustion of natural gas users using the most energy efficient technology available today. The network geothermal system will reduce approximately 8 tons of Carbon Dioxide equivalents (CO2e) per year per home using the Greenhouse Gases (GHG), Regulated Emissions, and Energy Use in Technologies (GREET) Model developed by the Argonne National Laboratory. The magnitude of overall carbon reduction will be assessed during planning and dependent on the size of the network.

4) **Drive clean innovation in industry.** As described in the MI Healthy Climate Plan, work should "encourage clean innovation hubs where private enterprises strategically co-locate and collaborate to develop and deploy new, cleaner manufacturing technologies and conduct research and development to reduce emissions from hard to decarbonize industries."[1] The essence of network geothermal systems is their hub-like ability to scale and pass benefits along to those connected to the network.

5) **Protect Michigan's air, land, and water.** The Planning Project supports air quality in Michigan by reducing emissions and mitigates environmental impacts associated with sourcing, transporting and burning fossil natural gas.

Primary metrics the Project will measure against include:

- Cost of energy savings per end user, measured in annual dollars saved
- Net energy efficiency impact, measured in the ratio of useful energy delivered to the amount of energy input into the system
- Carbon reduction, measured in tons CO2e and $/ton CO2e

V-F Work Plan

Provide a detailed work plan based on the requirements outlined in Part III-D Tasks. The applicant's impact study must be attached to the application. If applicant is applying for a Planning Grant, the Planning Narrative should be described in this section.

Bidder response:

1) Planning Project Narrative

[1] MI Healthy Climate Plan. (2022). Retrieved from MI Healthy Climate Plan (michigan.gov)

A. Planning Explanation

A networked geothermal system is a network of ground source heat pumps connected via common ground circuits as shown below in Figure 1. Network geothermal systems have two unique attributes. They share energy between demand centers, where a business that rejects heat for cooling purposes can be used down the street by a home for heating purposes, thereby greatly increasing energy efficiency. Secondly, these systems store excess heat in the earth during cooling seasons and withdraw that same heat months later during heating seasons just like a natural gas storage field. For these reasons, network geothermal systems drive energy efficiencies upwards of 600%.

Networked geothermal systems are mature technologies, used for decades on college campuses, and well considered the most energy efficient form of heating and cooling. Two natural gas utilities, Eversource and National Grid, have network geothermal demonstrations approved through public service commissions today with plans to expand.

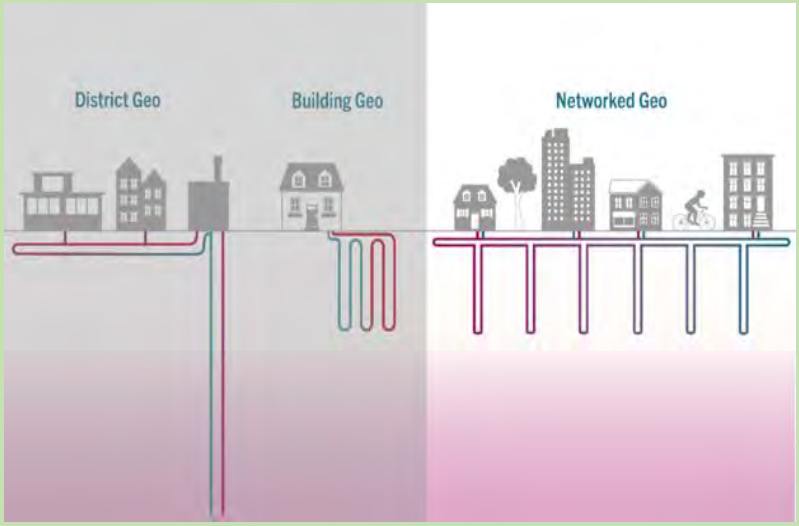

Figure 1 – Various geothermal system configurations

The outcome of the Planning Project is the following:

- Site and configure a network geothermal system in Consumers Energy's gas service territory given factors such as demographics, climate, geology, community interest, energy use diversity, and impacts to the existing system.
- Determine net energy impacts of the network geothermal system including incremental power consumption of heat pumps compared against energy efficiency gains.
- Determine additional costs to the electric distribution system and electric capacity needed to support a network geothermal system.
- Assess potential impacts to energy market prices due to additional energy demand.
- Determine how to best use existing tax subsidy incentives to reduce network geothermal system cost.
- Determine cost benefit analysis for homes and businesses on a network geothermal system including analysis for specific customer classes.
- Quantify the carbon reduction potential for the network geothermal system.
- Assess the scale of network geothermal systems throughout Consumers Energy's gas service territory.

Before the grant start date, a service territory wide assessment will occur to identify candidate locations ideal for network geothermal systems. Initial due diligence indicates Flint, Lansing, Jackson,

Battle Creek and Kalamazoo are potential sites. Initial community engagement activities will also occur before the grant start date to better understand community participation interest. Community engagement is described in further detail below.

Planning will occur in six (6) phases: site identification, site-specific geological evaluation, energy modeling, thermal resource assessment, infrastructure and implementation design and cost benefit planning. Grant award funds will be used to complete these six (6) phases.

i. **Site identification**: Site identification will be informed by service territory wide due diligence showing optimum locations for a network geothermal system based on MiEJ screen, population density, annual gross domestic product (GDP), GDP growth, demographic composition, diversity of energy load, current natural gas consumption, customer feedback and existing electric and gas infrastructure. These criteria will inform which location best supports disproportionately impacted communities, customer affordability and the MI Healthy Climate Plan. This phase will assess all criteria and select a site for further planning.

ii. **Geological evaluation**: Site specific geological evaluation will occur in two steps, deep (step one) and shallow (step two) evaluations. An initial deep test boring will evaluate geothermal capabilities of the site. Deep test borings will also evaluate glacial overburden and underlying bedrock characteristics to a depth of several hundred feet. The deep boring will provide thermal conductivity testing results to evaluate and obtain preliminary geothermal design characteristics.

Step two of the geotechnical evaluation will evaluate the shallow subsurface conditions to obtain parameters necessary for design of the overall system, including placement of network piping. Geotechnical investigations consisting of drilling soil test borings may include Standard Penetration Testing (SPT), undisturbed soil sampling using Shelby tubes, and other in-situ tests such as vane shear or groundwater monitoring. An overall subsurface geotechnical field assessment will be derived consisting of logging each test boring, performing soil/rock testing, and fluid testing.

Results of the field investigation and any corresponding recommendations will be documented in an engineering report including logs of test borings, a test boring location plan, results of thermal analysis, a summary of findings, and present evaluations, conclusions, and recommendations for the geothermal system.

iii. **Energy Modeling**: A thermal energy model will be developed using the determined geological characteristics. The thermal model will assess a network up to ten industrial/commercial structures and twenty residential structures. The model will be broken into clusters based on phasing and construction, which will be used in TRNSYS modeling software to determine the locations of all thermal energy resources within the system. The modeling software takes all energy load diversities and energy sharing into account when designing thermal resources.

This Phase will also look at incremental energy requirements for heat pumps and the associated energy load profiles across peak heating and cooling seasons to understand how the network geothermal system impacts electric loads, capacity requirements and market prices.

iv. **Thermal Resources**: This phase involves design and configuration of the network including geothermal heat exchangers to optimize energy and available space. This phase will also assess existing utilities within the street right of way (ROW). Other potential thermal resources such as water retention ponds, surface water systems or wastewater energy transfer (WET) systems that capture and reject heat into the community's main sewer line will also be assessed.

v. **Infrastructure Planning and Implementation**: This phase includes planning for mechanical and civil work to produce a conceptual distribution system design, geothermal fields, building interface, pumping stations, and central plant facilities as applicable. This phase also includes system descriptions, process diagrams, equipment lists, schematic arrangement drawings of central facilities, geothermal fields, and building interfaces. The outcome of this phase will be a schedule and conceptual execution plan including contracting methodology for development, construction, and operation of the system.

vi. **Cost benefit assessment**: Using the work in previous phases, this phase will develop a capital estimate, operations and maintenance estimate, infrastructure requirements, market price impacts, subsidy incentives, energy and associated cost savings, existing building retrofits required to connect to the network, and carbon reduction to determine the overall cost benefit attributable to specific customer classes. Capital cost estimates will include design, engineering, permitting, borehole drilling, drilling rig setup, ground circuit installation, heat pumps or circulating pumps, service connections to buildings, building envelope conversions and public ROW work.

B. Future project

Planning activities described above will provide the business case for a network geothermal system project at the selected site. A future project would continue with community engagement (described in detail below) and Michigan Public Service Commission collaboration to determine the appropriate path forward given results of planning activities.

Primary objectives from an initial project would be to demonstrate the reasonableness of scale, bill savings to customers, performance of shared energy circuits, energy efficiencies, and optimum configurations for Michigan's geology and the State's climate.

C. Timeline

See response box below for discussion on Planning Project timeline along with Attachment C, Gantt Chart.

D. **Impacts to Michigan citizens and businesses**

i. Planning activities and potential future projects have significant positive impacts to citizens and businesses, summarized below. Network geothermal is unique in that diverse energy loads are shared across the network, reducing energy consumption. In addition to energy sharing, network geothermal systems are preferred over air source heat pumps (ASHPs) due to superior energy efficiencies. The inherent properties and

heat transfer characteristics of water and soil allow network geothermal systems to provide efficiencies upwards of 600%. This is due to the ground maintaining stable temperatures all year, providing a reliable heat source compared to ambient air. Additionally, groundwater and soil are denser allowing better heat transfer characteristics than air. This means network geothermal systems obtain more heating energy per unit volume, which means greater energy efficiency. Further details are discussed in subpart E, MI Healthy Climate Plan.

Positive impacts to homes and businesses:

- Energy efficiencies upwards of 600%;
- Cost of energy savings due to high efficiencies;
- Less risk associated with water pipes as compared to natural gas pipelines;
- Emissions eliminated from combustion of fossil natural gas;
- Strong support for disproportionately and environmentally impacted communities;
- Economic development for businesses that support drilling, heating ventilation and air conditioning (HVAC), polyethylene pipe manufacturing and excavation.
- Excellent opportunity for clean energy job transition.

ii. A primary objective of planning activities and potential future project is understanding the willingness of existing natural gas customers to adopt geothermal heating technology. As noted, initial community engagement will occur ahead of the grant start date to educate on geothermal benefits, gauge participation interest and identify anchor users for specific locations. Anchor users are defined as higher load entities that reside near homes and other businesses.

As part of community engagement, a Community Stakeholder Engagement (CSE) Plan will be developed. A CSE uses a structured approach to building relationships with current stakeholders and disadvantaged communities. This framework is essential for proactively engaging potentially affected communities in upcoming projects, aiming to deliver community benefits, quality employment opportunities, and address any potential environmental concerns in a meaningful and impactful manner.

Upon reaching the grant start date, site selection will occur based on prior assessments and community feedback as described above. Concurrently with planning activities, a Stakeholder Engagement Group (SEG) will be created, ensuring a diverse representation of community priorities.

Throughout and after planning activities, CSE will be implemented. The two-way engagement will be dynamic, allowing for flexibility and adjustments based on insights gained through planning activities and engagement efforts. This approach will ensure a potential future project aligns with the evolving needs of community stakeholders. Feedback and insights collected from engagement activities will undergo a thorough analysis, serving as the foundation for continuous updates to engagement strategies and refining community priorities.

E. MI Healthy Climate Plan

The Planning Project directly contributes to the MI Healthy Climate goal of reducing emissions associated with heating homes and businesses 17% by 2030, achieving economy-wide carbon

neutrality by 2050 and maintaining net negative GHG emissions thereafter, while supporting disproportionately and environmentally impacted regions.

Environmental Justice and Pursue a Just Transition

As noted in the MI Healthy Climate Plan and research performed by Rewiring America, heat pump technology could provide immediate savings to Michigan homes. Network geothermal systems, which use heat pump technology, provide the highest cost of energy savings and are ideal for disproportionately impacted regions. The diverse energy load patterns of these regions where homes are near commercial and industrial sites make for ideal network geothermal systems.

In the coming decades, higher income residents are likely to adopt isolated electrified end uses first, leaving low-income customers subject to the fixed costs of the remaining natural gas network. Network geothermal evolves the natural gas system grid by grid, starting with low-income regions, so no one is left behind.

a. Michigan Environmental Justice (MiEJ) screen

The MiEJ screen will be used to help identify candidate locations for planning. The MiEJ screen uses 26 indicators summarized by 4 overall criteria to assess overall community impacts. Environmental indicators look at risk, pollution, or exposure to nearby facilities. Health and socioeconomic indicators look at a population's vulnerability or to pollution. As noted, "the screening tool is a useful first step in understanding or highlighting locations that require further review."[2] Based on initial screens, Flint, Lansing, Jackson, Battle Creek and Kalamazoo are potential sites for further evaluation.

b. MSHDA State-wide Housing Plan

Planning activities also support specific goals for the MSHDA 2022 Statewide Housing Plan. Planning activities will align with these goals throughout the process:

Goal 1.5: Increase opportunities for resident input throughout the development process.
Goal 4.3: Ensure that new housing development meets State climate and healthy housing goals and is affordable for the lifetime use of the building without increasing costs to residents.
Goal 4.5: Increase environmental sustainability, energy efficiency, and weatherization in housing rehabilitation and/or preservation.

c. Just transition of workforce

There are similarities between shared geothermal networks and natural gas networks, including materials, installation methods of underground pipe, permits, drilling boreholes, right of way work, and monitoring the system conditions to ensure safety and reliability service for customers. There are low barriers to transition due to these close similarities. For example, fluid pipes in network geothermal systems use the exact same polyethylene pipe material as natural gas distribution systems. This enables a quicker and more equitable transition than the current building-by-building approach for air source heat pumps.

Clean the Electric Grid

Network geothermal systems support a cleaner electricity grid by using the lowest total energy over the course of a year to heat and cool homes. Specifically, network geothermal systems reduce peak heating and cooling loads and mitigate the need to potentially expand electric infrastructure. This benefit will become more valuable as shoulder seasons potentially become shorter.

[2] MiEJ Screen. (2023), retrieved from MiEJScreen-Factsheet.pdf (michigan.gov)

Analysis performed by HEET in Figure 2 shows the incremental peak load in high demand seasons using various electrification technologies for space heating.[3] With efficiencies upwards of 600%, it is clear network geothermal systems have negligible impact to peak electric load in a highly electrified future. This ultimately helps citizens of Michigan avoid cost impacts of adding new electric capacity.

Like battery storage, network geothermal systems use the earth as a thermal battery. In this way, intermittency issues tied to solar and wind energy are mitigated by requiring less energy during off-peak hours.

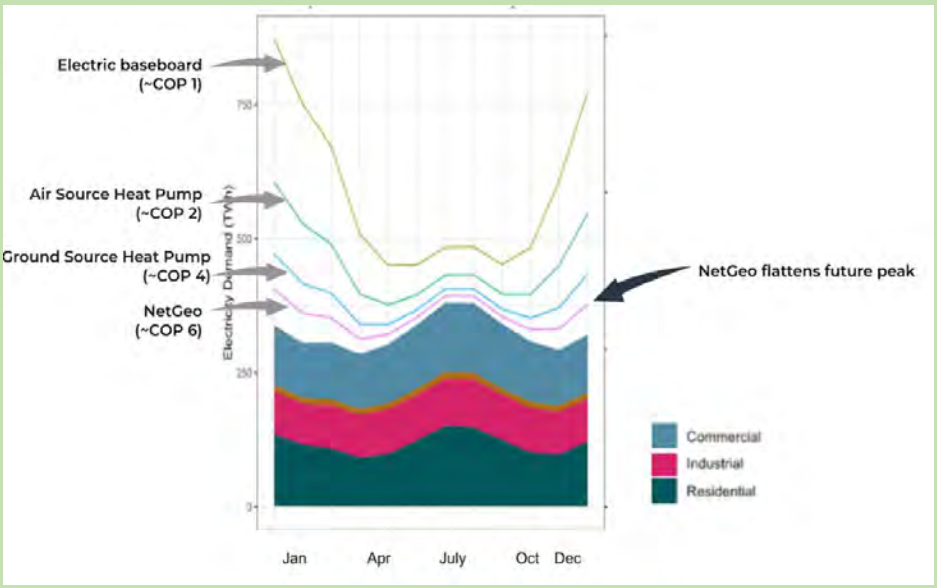

Figure 2 – Peak electric loads by technology

Repair and Decarbonize Homes and Businesses

The MI Healthy Climate Plan assessed that "replacing traditional fossil fuel use with cost-effective technologies that rely on electricity" can effectively decarbonize building heating.[4] The Planning Project will determine the extent of carbon reduction in Michigan using network geothermal systems. With natural gas showing a lifecycle emission of approx. 80 grams CO2e per megajoule, network geothermal systems could demonstrate meaningful impact in reducing carbon when scaled.

Prior analysis by Consumers Energy, confirmed by 3rd party experts, indicates that the combination of clean fuel technologies provides the most cost-effective solution to reaching the MI Healthy Climate Plan goals. Each technology including network geothermal, air source heat pumps, renewable natural gas, hydrogen, carbon capture, synthetic gas and long-term storage all reduce carbon affordably in unique sectors of society. Network geothermal systems may provide the most cost-effective form of electrification for low-income regions which this Planning Project seeks to understand.

Drive Clean Innovation in Industry

The Planning Project seeks to understand the scalability of network geothermal using a hub-like approach. Like municipal water and natural gas systems, network geothermal systems can be added onto making the system more diverse and energy efficient. Starting with a central hub network,

[3] HEET. (2023). Networked Geothermal. Retrieved from Networked Geothermal Wiki (gastogeo.wiki)
[4] Department of Environment, Great Lakes, and Energy. (2022). MI Healthy Climate Plan. Available at MI Healthy Climate Plan (michigan.gov)

planning activities will focus on the extent to which network geothermal can become scaled regional hubs.

Protect Michigan's Air, Land and Water

As noted above, the Planning Project supports air quality in Michigan by reducing emissions associated with sourcing, transporting and burning fossil natural gas. Network geothermal systems are ideally installed in existing rights of way for existing public utilities, which mitigates impact to undisturbed land and areas not already addressed with existing permits.

2) Potential funding sources to implement of project(s)

Specific for this planning grant request, Consumers Energy would seek funds for a future project through collaboration with the Michigan Public Service Commission and a potential future rate case.

Applicant must include a timeline and Gantt chart. Please attach as a separate document if necessary.

Bidder response:

Timeline for planning starts in December 2024 and continues through October 25. Prior to these planning efforts, a service territory wide assessment and initial community engagement will occur throughout 2024 to locate candidate sites and introduce the network geothermal technology to communities. At the start of the grant period, a site will be identified for detailed planning activities, which runs through geological assessment, energy modeling, thermal resource configuration and development of an implementation plan and cost benefit analysis. Planning work will complete on or before October 2025 with post community engagement occurring after. A Gantt Chart for these activities is shown on Attachment C.

	Finish
Identify and assess candidate sites	Dec-24
Establish stakeholder matrix	Dec-24
Site identification and conceptual network design	Feb-25
Engage community on assessment, technology and timeline	Feb-25
Engage key businesses with potential to serve as system anchors	Mar-25
Site-specific geological evaluation	Apr-25
Energy modeling	May-25
Thermal resource assessment	Jun-25
Infrastructure design	Aug-25
Implementation approach	Oct-25
Post-planning engagement with community	Jul-26

V-G Management Summary

(1) Describe management procedures that will be used by the organization to complete the proposed project.

(2) Describe the organization's quality control measures, including measures for ensuring compliance as well as eligibility determination. In your description, include information regarding separation of duties.

(3) Selected applicant(s) must provide fiscal control and financial accounting procedures that will

assure that grant funds will be accounted for and properly dispersed in a way that will allow the Issuing Office to clearly review and verify all grant related expenditures. Describe the organization's internal control policy:

- Identify the type of accounting system/software the organization will use to account for grant funds.
- Identify how duties will be separated.
- Describe how the organization will account for grant funds, i.e., will grant funds be placed in a separate bank account, will the grant funds be assigned a unique code(s) within the organization's overall accounting system. Ensure funds are maintained in a non-interest-bearing account.
- Indicate whether internal and external audits of the organization's operations are performed on an annual basis. Selected applicant(s) must provide a copy of the organization's most recent audited financial statement as well as a copy of the organization's most recent single audit as required by OMB Circular 200.36.

(4) Describe your agency's data security plan.

Bidder response:

1) Management procedures to be used include standard financial governance and project management practices. Financial governance refers to the review and potential approval of budgets, current year funding changes and financial management of contracts. Planning activities will also use standard project management practices referring the routine review of project status measured against their progress in achieving pre-defined metrics.

2) Consumers Energy is audited annually by a public accounting firm and has received unqualified opinions. Additionally, the Company has a separate public accounting firm, KPMG who performs internal audits annual based on a three-year risk assessment.

3) The Company will use our existing system SAP (System Applications and Products) to account for the potenial of grant funds. Proper internal controls, which would include segregation of duties, have been established and are reviewed as a part of the external and internal audits annually. The Company's management annually evaluates the effectiveness of its internal control over financial reporting and has deemed the controls effective. These controls are also audited annually by our external auditors. The Company will use various unique identifiers within our accounting system, SAP, to ensure all grant funds are properly accounting for and segregated from other funds. As noted above both external and internal audits are conducted on an annual basis. Below is a link to Consumers Energy's most recent financial filing.[5]

4) Consumers Energy has a comprehensive cybersecurity program aimed at securing our sensitive data and critical infrastructure. In addition, Consumers Energy has a privacy program aimed at ensuring data is handled appropriately at the company. Both programs include a number of technical controls, polices, procedures, standards and awareness activities.

V-H Personnel

Selected applicant(s) must be able to staff a project team that clearly possesses skill and experience relative to the project.

[5] Consumers Energy. (2024). Financial Information. Retrieved from CMS Energy Corporation - Investors - Financial Information - Annual Reports

1) Applicant(s) must identify the authorized contact person and key personnel to be involved with this project by name and title and provide a brief summary of their experience, qualifications, and the work to be performed.
2) If other organizations will be playing a role in the proposed project, provide sufficient background information that will give the MPSC a reasonable understanding of each organization's qualifications.
3) Include a detailed organizational chart including names, titles, and geographic location of all individuals that will contribute to the project.
4) If personnel or other organizations have signed a confidentiality agreement, attach a copy along with a list of personnel and the date that the confidentiality agreement was signed.

Bidder response:
The Planning Project will be staffed and managed with industry leading experts covering end to end details of the network geothermal technology. An organizational chart is shown in Figure 3 with qualifications for individuals described.

1) Authorized contact person: The following individual is the authorized contact person on behalf of Consumers Energy:

Neal Dreisig
Sr. Strategy Manager
989-239-8071
neal.dreisig@cmsenergy.com

2) Consumers Energy

- Neal Dreisig, Sr. Strategy Manager: Neal Dreisig is a Sr. Strategy Manager responsible for overseeing the decarbonization strategy for Consumers Energy's natural gas system. This includes renewable natural gas, hydrogen, carbon capture, electrification technologies and other alternative low carbon fuels. Prior to this, Neal held multiple roles within project management and generation operations. Neal holds a Bachelor of Science degree in construction management from Michigan State University and a Master of Science degree in Management from Colorado State University. Neal is also a certified Project Management Professional.

- Seth Epstein, System wide energy efficiency planning: Seth Epstein is Senior Product Manager at Consumers Energy where he leads the residential demand response product - AC Peak Cycling. Seth has deep knowledge of residential and commercial utility energy efficiency and demand response program design and delivery. He earned his master's degree in Natural Resources and Environment with a certificate in Industrial Ecology at the University of Michigan in Ann Arbor and his bachelor's degree in philosophy at St. Lawrence University in New York.

- Brian Snyder, Assessment Planning Engineer. Brian manages assessment planning, threat assignment, and risk analysis for the Transmission (gas pipeline) Integrity Management Program at Consumers Energy. This includes inline inspection, direct assessment and direct examination, and the analysis of probabilistic risk modeling to build forecasted work plans and budget. Previous experience includes HVAC design and energy modeling for commercial buildings specializing in healthcare applications. Brian has a Bachelors of Science, Mechanical Engineering, from the University of Michigan Dearborn, a licensed Professional Engineer in the State of Michigan, and a LEED Accredited Professional

- Dena Isabell, Community Engagement Manager. Dena leads statewide engagement internally and externally for major projects including coal plant decommissioning, gas pipeline projects, major hydro facility investments, significant electric reliability projects and all non-solar renewable energy development. Dena has an MBA from Ferris State University and a Bachelors in Biosystems Engineering from Michigan State University.

Salas O'Brien
Salas O'Brien is an engineering and technical services firm focused on advancing the human experience through the built environment. Salas O'Brien provides decarbonization expertise, leadership, and support to plan, design, and implement ground source heat exchange and solar photovoltaic systems that achieve exceptional operational cost savings and drastic carbon emissions reductions. To date, more than 400 geothermal projects are completed, providing over 84,000 tons of system capacity; and, over 100mW of installed solar, over 50mV of fuel cells, and over 200 central plant replacements and modernizations.

- Jeff Urlaub, Principal in Charge: Jeff has been responsible for the design and implementation of innovative, environmentally responsible solutions for clients across the United States. Jeff has more than 20 years of professional engineer experience in HVAC design, project management, design of engineered systems and mechanical services, with an emphasis in renewable energy, energy analysis and geothermal design.

- Rick Humphries, Project Manager: Rick is a mechanical engineer with a background in thermal systems design. Over the past decade he has focused on the creation of project companies to serve specific energy needs. Rick approaches projects in a holistic way, considering the application of technology, market drivers, and economic incentives to produce outcomes.

- Brian Urlaub, Geothermal Exchange Expert: Brian oversees Salas O'Brien's geothermal projects and is involved in procurement, design, and project management. He has 25 years of experience in the geothermal industry, beginning with installation and servicing in the field, then transitioning to design and sales. He is adept at working with clients to develop solutions that meet their goals while responding to site conditions, as well as schedule and budget expectations.

- Andy LaFerriere, Energy Analyst: Andy is an energy engineer with over a decade of experience in commercial, industrial, and institutional building analysis and campus energy master planning. His skillset ranges from basic screening of energy efficiency projects to advanced analysis, design, and optimization of large central plants, including an array of alternative energy technologies. Throughout his career he has played a key role in the development of some of the largest geothermal projects in the world.

NTH Consultants
NTH Consultants, Ltd. (NTH) provides practical and innovative solutions to a multitude of engineering challenges. A full service geotechnical, infrastructure and environmental engineering firm, NTH has been providing professional consulting services to public and private clients throughout the United States as a Michigan corporation since 1968. NTH Consultants' extensive knowledge of environmental regulations and conditions helps clients manage both state and federal environmental regulations for ecological, wetlands, habitat restoration, hazardous waste management, wastewater discharge, air emissions, hazardous materials storage, and health and safety issues.

- Craig Johnson, Senior Principal Engineer: Mr. Johnson offers 22 years of energy industry leadership, project management, and technical consulting, with 13 years of enterprise-wide utility operations, engineering, regulatory compliance, risk identification and mitigation, and overall program leadership. Within the utility roles, he had responsibility for all aspects of natural gas delivery

(production wells through customers burner tip), electric distribution operations and engineering, utility scale solar generation development and operation, and leadership of a coal-fired generation facility and associated landfill.

- Mark Hushebeck, Senior Project Geologist: Mr. Hushebeck has 37 years of experience in various geological aspects of geotechnical engineering, including: landslide evaluations and stabilizations, site feasibility, dams and levees, geologic mapping, field exploration, directional drilling studies, forensic evaluation and construction monitoring, land use planning, and preparation of bidding and specification packages. His experience includes large hillside residential developments, roads and highways, industrial / commercial structures, motor sports complex developments, geophysical and geotechnical instrumentation setup/monitoring, geologic field mapping, distressed single-family and multi-family residential building evaluations, resource potential evaluations and Level 1 environmental impact reports.

3) Organizational chart:

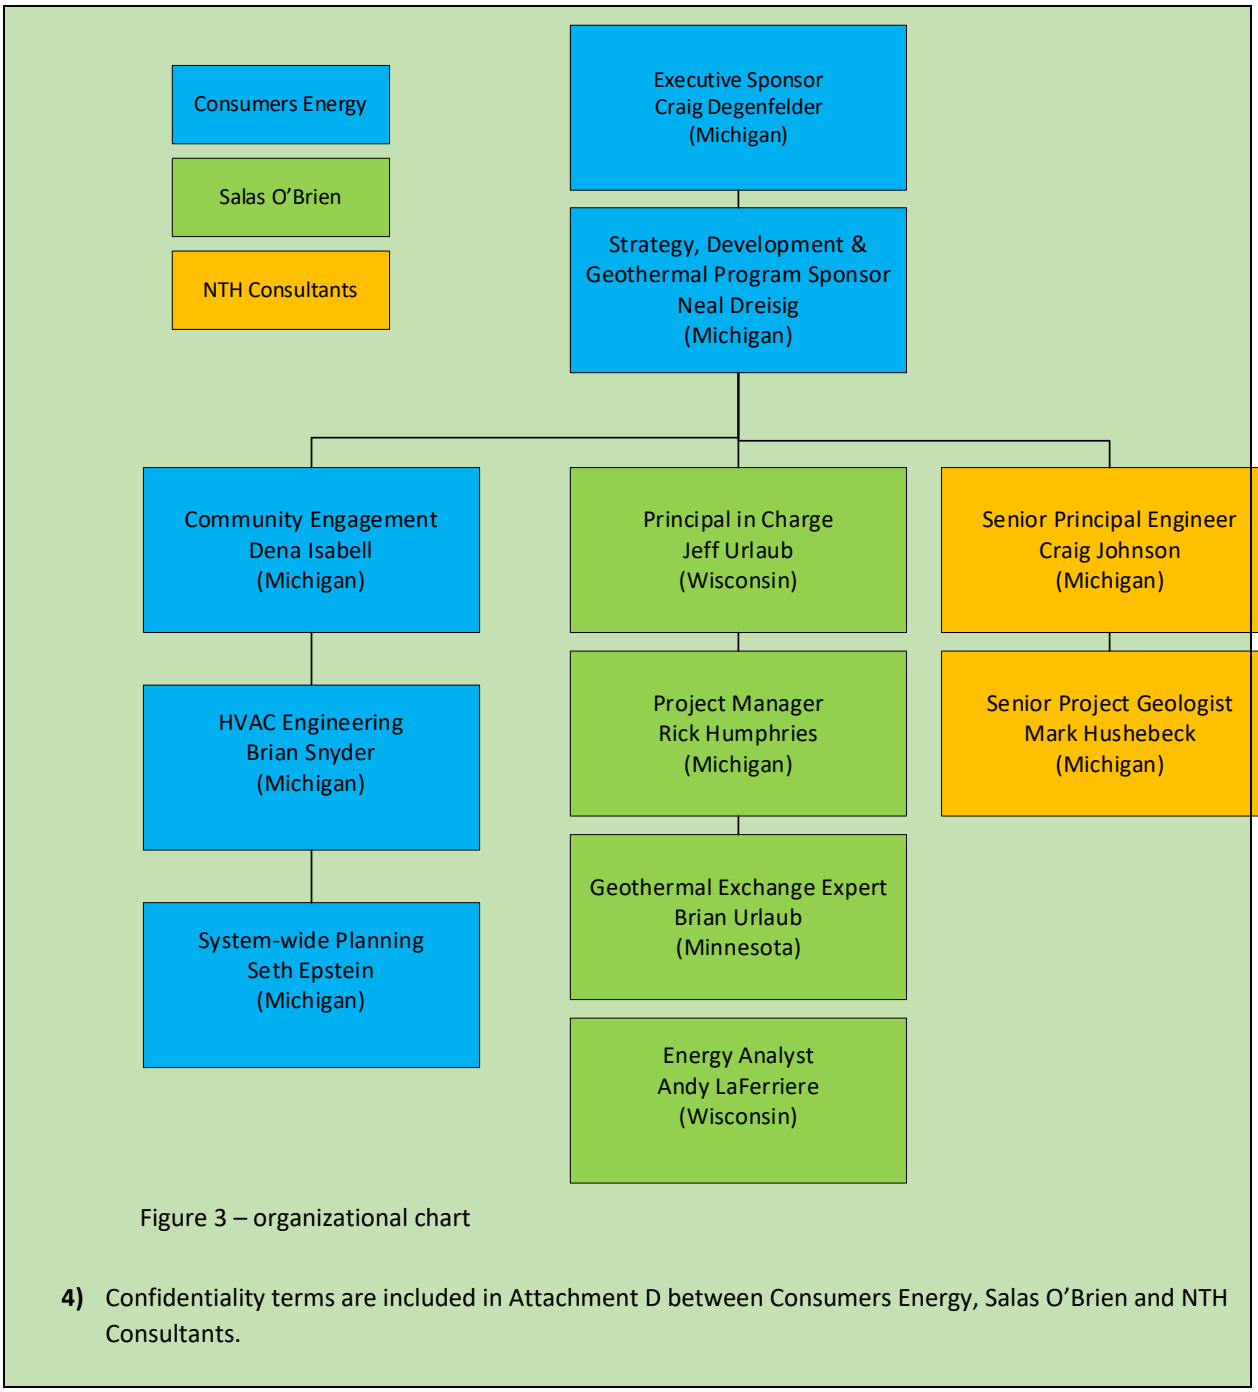

Figure 3 – organizational chart

4) Confidentiality terms are included in Attachment D between Consumers Energy, Salas O'Brien and NTH Consultants.

V-I Budget

To enable the MPSC to evaluate all project costs, applicant(s) will submit a proposed budget and corresponding budget narrative. Please see Attachment A for the required budget format. The budget and narrative must include only Renewable Energy and Electrification Infrastructure Enhancement and Development Grant Program funds in the budget; do not include matching, leveraged, cost share or any other type of supplemental funds. The budget narrative must identify the budget line item and number, provide a detailed description for each line, and include individual unit prices.

Selected applicant(s) will be required to provide supporting documentation for all grant expenditures incurred during the term of the grant. Accounting records must be supported by source documentation

including, but not limited to, general ledgers, time sheets, payroll registers, invoices, check copies and bank statements, or cancelled checks. Expenses will be verified based on actual expenditures incurred within the grant period that are supported by source documentation, not budgeted amounts.

1) **Budget Changes** – Any changes to the budget must be pre-approved by the MPSC Grant Administrator. Changes in the budget of less than 5% of the total line item amount, or $2,000 (whichever is greater), do not require a formal amendment; however, a revised budget should be submitted to the MPSC Grant Administrator for approval. The allowable transfer should be calculated as less than 5%, or $2,000 (whichever is greater), of the total line item that the funds are being transferred from.

   Cumulative changes in the budget equal to or greater than 5% of the total line item amount, or $2,000 (whichever is greater), may be permitted only upon prior review and written approval by the MPSC Grant Administrator. A formal grant amendment must be signed by both the Grantor and Grantee.

2) **Disallowed Costs** – Disallowed costs include but are not limited to the following: sick pay, vacation pay, holiday pay, bonuses, overtime, tuition reimbursement/remission, vehicle allowance, seminars, conferences, meetings, subscriptions, dues, and memberships.

3) **Administrative Costs** – Administrative costs cover expenses related to general administrative functions and coordination of functions and oversight directly related to the Renewable Energy and Electrification Infrastructure Enhancement and Development Grant Program administrative functions. Administrative costs should include costs of goods and services required for administrative functions of the program; travel costs incurred for official business in carrying out administrative activities or the overall management of the Renewable Energy and Electrification Infrastructure Enhancement and Development Grant Program; costs of information systems related to administrative functions; and contractual services related to sub-recipients or vendors that are solely for the performance of administrative functions. **Total direct administrative costs must be identified and labeled clearly.**

4) **Budget Requirements** – The proposed budget will display three (3) headings identified as the: Line Item, Budget Category, and Total Grant Request. The budget line items that need to be included, at a minimum, are listed below. The budget should reflect the best estimate of actual costs using whole numbers. Please refrain from using decimals or formulas. Refer to the budget example provided in Attachment A.

   - **Personnel** – In the budget, include the name, job title, and salary for each staff position to be paid for by the grant. Time sheets and payroll registers must be submitted for each staff position, and hours worked must be grant related. Fringe benefits may not exceed 35% of each employee's salary. Fringe benefits will be reimbursed based on actual expenditures per employee up to 35%, not on budgeted amounts. Allowable benefits include: health, dental, and optical insurance, employer-paid Social Security and Medicare tax, Michigan and Federal unemployment tax, and other miscellaneous fringe benefits (life insurance, long- and short-term disability insurance, worker's compensation, and retirement program contributions up to 4%). Within the budget narrative, applicant(s) must provide details on the organization's method of calculating fringe benefit expenses that will be charged to the grant including whether fringe benefits are calculated on an annualized basis or based on the length of the grant term.

     The budget narrative must include the number of weeks the individual will work on the grant; number of hours per week a full time employee of the organization is expected to work; a description of the work to be performed by each individual; the estimated hours to be worked; actual pay rate; the fringe benefit percentage being charged to the grant for each employee; the percentage of the employee's time allocated to the grant; whether each employee is salaried-exempt, salaried-non-exempt or hourly; and any other applicable information related to the individual's duties and responsibilities in connection with this grant.

     Individuals that are not on selected applicant(s)'s payroll, e.g., independent contractors, individuals

receiving a Form 1099, temporary workers, etc., must be placed under the Contractual Services budget category. Only employees on the selected applicant(s)'s payroll should be included in the Personnel budget category.

- **Supplies, Materials, and Equipment** – Specify item(s) and cost. The budget narrative should include the anticipated cost of each item, a detailed explanation of the item's purpose, and how it relates to the project being funded. Be as detailed as possible.

- **Contractual Services** – These services must be competitively bid. Individuals that are not on selected applicant(s)'s payroll, e.g., independent contractors, individuals receiving a Form 1099, temporary workers, etc., must be placed under **Contractual Services**. When competitive selection is not feasible or practical, the selected applicant(s) agrees to obtain the written approval of the MPSC Grant Administrator before making a sole source selection. Selected applicant(s) must provide a copy of contracts, memoranda of understanding or agreements signed by selected applicant(s) and contractors.

  Selected applicant(s) assumes responsibility to select subcontractors on a competitive basis. A minimum of three (3) bids must be solicited and proposals must include, at a minimum: (1) name of selected applicant(s), grant number, and grant period; and (2) the type, number, and description of projects as described in the proposal.

  Selected applicant(s) must provide the MPSC Grant Administrator with the solicitation, list of vendor responses (including amounts), and name of the selected vendor. Selected applicant(s) must maintain bids on file at their place of business according to Section II-H, Records Maintenance, Inspection, Examination, and Audit. The MPSC Grant Administrator will reserve the right to request a copy of all bids for services that are competitively bid.

  Selected applicant(s) must award the project to the lowest bid unless the MPSC Grant Administrator has given prior written approval for selection of a higher bid. Selected applicant(s) must provide a written justification for the selection of a higher bid. When awarding subcontracts, the selected applicant(s) must ensure that preference is given to products manufactured in or services offered by Michigan-based firms.

- **Other Expenses** – This category is solely for use by organizations charging a per-case fee for work performed by subunits or internal agencies within the organization that do not require a competitive bid, i.e. contract, memorandum of understanding or any other type of signed agreement.

- **Indirect Costs** – Indirect costs are costs not directly or specifically related to the grant program. Indirect costs are costs of administering the organization and must be spread over a number of products, services, or grant programs proportionately. Examples include office supplies and equipment, utilities, rent, maintenance and repair, insurance, accounting and bookkeeping services, and legal services. Non-cash expenses like depreciation, amortization, and depletion are not allowable indirect costs under this grant. **Total indirect costs must be identified, labeled clearly, and may not exceed an amount equal to 10% of the total direct costs.**

  Selected applicant(s) will be reimbursed for its proportional share of indirect costs. This means the MPSC should be allocated a portion of the selected applicant(s)'s indirect costs and not 100% of the organization's total indirect cost.

  Indirect costs should be displayed on the face of the budget on a single line item and the indirect rate should be rounded to six (6) decimal places. The budget narrative should contain a list of indirect costs, how the selected applicant(s) determined its indirect costs, and the percentage rate calculation for reimbursable indirect costs. Selected applicant(s) is not required to provide documentation supporting indirect costs; however, documentation verifying the costs must be retained by the selected applicant(s).

Indirect costs should be displayed on the face of the budget on a single line item and the indirect rate should be rounded to six (6) decimal places. The budget narrative should contain a list of indirect costs, how the selected applicant(s) determined its indirect costs, and the percentage rate calculation for reimbursable indirect costs. Selected applicant(s) is not required to provide documentation supporting indirect costs; however, documentation verifying the costs must be retained by the selected applicant(s).

5) **Grant Expenditure Guidelines** - To ensure efficient review and approval of grant expenditures, selected applicant(s) will be provided additional guidelines to assist with calculating and determining accurate and appropriate grant expenditures.

6) **Budget Subtotal** - Each budget category should have a subtotal displaying the total anticipated amount to be expended, and the budget should include a subtotal for total direct project costs and a sum of total project costs.

7) **Travel** - In the event that any necessary travel is anticipated, all expenses must be reflected in the applicant(s) hourly rate.

8) **Budget Modifications** - After grants are approved by the MPSC, modifications of proposals and budgets may be necessary. If the MPSC does not approve the total amount requested in the original proposal, selected applicant(s) will be required to submit a revised proposal, budget and budget narrative for the purpose of entering into a Grant Agreement. New line items to the revised budget are not allowed.

9) **Unexpended Grant Funds** - Selected applicant(s) assumes the responsibility of ensuring all unexpended grant funds are returned to the State of Michigan at the end of the grant period. Failure to do so may render selected applicant(s) ineligible for future grant awards and/or subject to legal action.

10) **Commingling Grand Funds** - Selected applicant(s) may not commingle grant award funds with current or future grant awards. All funding sources must be managed and accounted for separately.

Bidder response: Templates for the Budget and Budget Narrative are attached to the RFP Response document located on the Renewable Energy EIED webpage. In this bidder response, add any information not included in the Budget or Budget Narrative.

See below completed budget templates and narrative

V-J Current and Prior Experience and Funding Disclosure

Current and prior experience is important to the selection process. Proposals submitted by applicant(s) should include:

1) A description of the organization's experience in conducting the type of work proposed. Include current activities and activities for the previous ten years. Include project results.

2) If applicant(s) received a similar grant award from the State of Michigan in prior years for the type of project proposed, provide a summary of project accomplishments. Include a plan for addressing and resolving past problems.

3) Current funding source(s) and the level of funding for the current year and the previous ten years.

4) If additional dollars beyond these grant funds are being used for this project, indicate the source and amount.

5) If applying for a planning grant, identify potential funding sources (both internal and external) that

are secured to undertake construction of facilities or implementation of programs that a planning grant is intended to identify.

Bidder response:

1) Consumers Energy has assembled a team of highly experienced individuals and firms familiar with Michigan, its geological characteristics and demographics. This team includes Consumers Energy, Salas O'Brien and NTH Consultants.

Consumers Energy

Consumers Energy has over 100 years of experience with nearly all components of a network geothermal system including underground survey, drilling, energy efficiency, pipeline installation, right of way work, municipality coordination, and community engagement.

Salas O'Brien & NTH Consultants

Together Salas O'Brien are NTH Consultants are national leaders in the planning, design, and implementation of geothermal systems, central energy plants, and district energy systems, completing over 400 associated geothermal projects. Select project results are shown below.

U21806-MNSC-CE-0039_ATT 4

Converting Ford's Dearborn Campus to District Energy

Ford Motor Company Dearborn Campus - Low Entropy Campus Master Plan and Central Utility Plant DEARBORN, MI, USA

SERVICES
District Systems

COMPLETION YEAR
2020

CONSTRUCTION COST
Confidential

SIZE
100,000 square feet plant serving up to 9 million square feet of facilities

Redeveloping six million gross square feet of research, engineering, and design facilities, Ford is upgrading to a modern district energy system. Salas O'Brien developed a Low Entropy Campus Master Plan and provided design services for the new Central Energy Plant and distribution systems. As the project prime, we managed all design disciplines including architectural services and structural engineering.

The facility includes: a 34 MW combined heat and power system with two Solar Titan 130s; a 16,000-ton chiller plant with heat pumps and high-efficiency cooling-only chillers; and, 40,000 ton-hours of thermal energy storage.

Results

- 40,000 ton-hours of thermal energy storage
- 16,000 ton chiller plant
- 34 MW combined heat and power system

Scalable single-family neighborhood geothermal

Mattamy Homes, Berczy Glen MARKHAM, ON, CANADA

SERVICES
Geothermal and Renewables

SIZE
500,000 square feet; 312 Homes

COMPLETION YEAR
2024

PROJECT PARTNERS
Enwave Energy Corporation

Upon completion, Ontario's 327-home Berczy Glen development will be the first residential neighborhood in Canada to have its heating and cooling needs met by a central geothermal system. Salas O'Brien designed a net zero carbon system, 3.5 to 4 times more efficient than the conventional natural gas alternatives. Homeowners are expected to see 30-50% reduction in monthly utility bills.

The geothermal system consists of 170 vertical loop boreholes, 850' deep, distributed entirely under neighborhood streets in twelve pods, connected by a two-mile ambient water loop. Circulation pumps serving the loop and individual pods are housed in subgrade vaults, eliminating visible infrastructure.

The system will be maintained by Enwave Energy Corporation, demonstrating the feasibility of community-scale geothermal systems for Berczy Glen developers, Mattamy Homes.

80% reduction
in system carbon emissions

100% reduction
in household carbon emissions

Evaluating conversion options

Xcel Energy Denver DENVER, CO, USA

SERVICES
District Systems

SIZE
120 Buildings

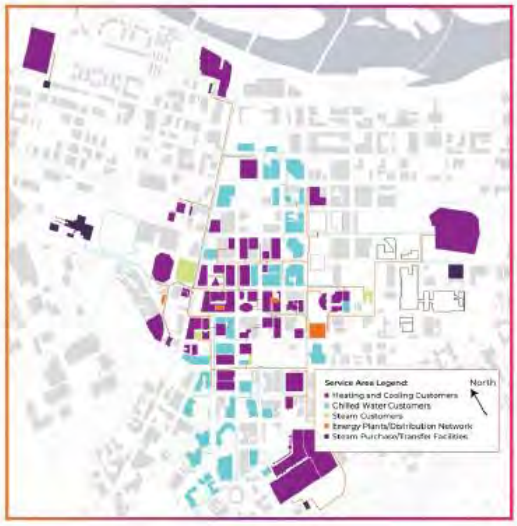
COMPLETION YEAR
In Progress

CONSTRUCTION COST
Confidential

Our team is currently performing a study on Xcel Energy's district steam system to review technological options, technical feasibility, and costs for converting to an ambient temperature heating/cooling system. Xcel would convert the existing steam system to an ambient temperature system and the second would utilize the chilled water system as an ambient temperature loop. The study will evaluate options to temper the ambient loop fluid including, the use of a community ground source heat exchanger, integration with the central steam plant, integration with the district chilled water system, use of system renewable electricity that would otherwise be curtailed, waste heat recovery, and thermal balancing that leverages customer loads.

The study will consider whether the steam system can serve existing service customers with a technology or technologies that align with state sector-based and state-wide GHG reduction targets as well as any requirements of Energize Denver. The study will provide a baseline of information on the technical feasibility and costs of the ambient temperature heating/cooling system.

Minneapolis



District energy solution to serve a new mixed-use development

Harmonia - Mixed Use Building MINNEAPOLIS, MI, USA

SERVICES
District Systems

SIZE
1,300,000 square feet

COMPLETION YEAR
Expected xxxxx

CONSTRUCTION COST
Confidential

The project through Cordia Energy aims to investigate a solution to serve a proposed development, dubbed "Harmonia" will cover a city block in downtown Minneapolis and will include two residential buildings with mixed use on the ground floor and one commercial office building.

Our team is developing a thermal profile based on current project concepts and programming to asses thermal needs of the future district and gain a preliminary understanding of geothermal system feasibility. We are evaluating three general geothermal system concepts which include open loop production and re-injection wells, open loop Darcy system, and closed loop vertical bore for ground heat exchange. A unique challenge is that below grade parking consumes the entire footprint of the property up to and below the sidewalks that border the city block, which would require both open and closed loop systems to be installed. While open loop looks like a promising solution from a thermal energy perspective; regulatory constraints will prevent locating well heads below grade without a variance. The variance will not likely be granted, thus eliminating the feasibility.

2) Consumers Energy received two grant awards in 2023 for the Swisslane and TDI Farm renewable natural gas Projects. These projects remain on schedule for in-service in 2026. Since award, both projects actively engaged the community achieving ordinance approval for the Swisslane Project to apply for a special land use permit. The Projects are managed through Consumers Energy's Enterprise Project Management Office, which requires due diligence and oversight reviews to highlight problems, incorporate lessons learned and ensure projects remain on track to achieve business case results.

3) Funding sources for the current year and previous 10 years is through our regulated rates to customers. The funding for this work is intended to be covered directly by the planning grant award.

4) The funding for this work is intended to be covered entirely by the planning grant award. Funding for work prior to the grant start date including community outreach and service territory wide assessments for potential network geothermal sites will use funds in a study-based balance sheet account until a capital asset or O&M expense is determined.

5) Specific for this planning grant request, Consumers Energy would seek potential funds to undertake construction of a potential project through collaboration with the Michigan Public Service Commission and a future rate case.

V-K Additional Information and Comments

Include in this section any other information that is believed to be pertinent but not specifically requested elsewhere in this RFP.

Executive Summary

In its March 5, 2020 Order Approving Settlement Agreement in Consumers Energy's *2020-2023 Energy Waste Reduction (EWR) Plan*, the Michigan Public Service Commission (MPSC) authorized the Company to invest in cold-climate heat pump (CCHP) initiatives for both income-qualified and non-income-qualified residential customers and business customers to test the efficacy, performance, and customer experience, among other factors. The Settlement Agreement[1] required the Company to submit an interim and final report delineating cold-climate heat pump (CCHP) initiative findings with the Company's 2020 and 2021 EWR Reconciliation filings, respectively. This report supplements the CCHP final report submitted as required by the March 5 Order and documents 2021 evaluation activities.[2]

The approved Settlement Agreement included both increased investment to support the income-qualified program performance metric associated with CCHP installations and a CCHP retrofit pilot initiative targeted to residential homes and businesses heated with electricity or heating fuels not regulated by the Michigan Public Service Commission, such as delivered propane or fuel oils. Given the challenges with implementing the CCHP initiatives, as well as unanticipated delays due to COVID-19, participation for income-qualified single-family and small commercial customers in 2021 occurred late in the year. This late participation has delayed the evaluation impact analysis for these two initiatives. All impact evaluation efforts will be completed in 2022 and the report will be filed in the case docket.

The main objective of these CCHP Initiatives was to demonstrate the potential for energy savings by replacing inefficient heating and cooling equipment with CCHPs. Consumers Energy targeted four distinct customer groups:

- Residential customers with electric or delivered fuel heating
- Income-qualified single-family customers with electric or delivered fuel heating
- Income-qualified multifamily customers with electric heating
- Small commercial customers with electric or delivered fuel heating

Consumers Energy designed its CCHP Initiatives to address both the supply and demand for CCHPs. The initiatives were implemented through Consumers Energy's existing residential, income qualified and small business product offerings. They aimed to strengthen trade allies' capabilities to install and service advanced heat pumps while increasing customers' awareness of and confidence in heat pumps as a viable, affordable, and environmentally friendly home heating source.

The CCHP Initiatives' incentives varied by customer type and ranged from $1,000 for market-rate customers to the full cost of installation for income-qualified and small business customers.

[2] Cadmus. 2020-2021 Cold-Climate Heat Pump Initiatives Final Report. May 18, 2022.

CADMUS

Consumers Energy marketed the initiatives through participating contractors, who were familiar with heat pump technology and had been educated about the offering, as well as through mass marketing campaigns and other Consumers Energy network partners like Habitat for Humanity. Table 1 through Table 3 shows participation and investments through December 31, 2021, by customer group and year.

Table 1. 2020 and 2021 Cold-Climate Heat Pump Participation and Investment

	Residential Market Rate	Income Qualified		Small Commercial	Total
		Single-Family	Multifamily		
2020 - 2021 Target	50 [a, b]	160	558	25 [b]	**793**
2020 - 2021 Installations	53	179	663	26 [c]	**921**
Percentage of Target	106%	112%	119%	88%	**116%**
Total Investment	$579,297	$3,184,143	$3,664,670	$999,000	**$8,427,110**

[a] The original Settlement Agreement targeted 100 heat pumps. Per the end of July 2020 reforecast; this was adjusted to 50 heat pumps.

[b] While the income qualified targets are specific to each year and summed in this table, the residential market rate and small commercial targets represent the total adjusted targets for the two-year period.

[c] This is updated from the 2020–2021 Cold Climate Heat Pump Initiatives Final Report.

Table 2. 2020 Cold-Climate Heat Pump Participation and Investment

	Residential Market Rate	Income Qualified		Small Commercial [a]	Total
		Single-Family	Multifamily		
2020 Target	100 [b]	100	225	25	**450**
2020 Installations	5	78 [c]	276	0	**359**
Percentage of Target	5%	78%	123%	0%	**80%**
2020 Investment	$258,771	$1,447,290	$1,523,558	$225,204	**$3,454,823**

[a] The small commercial initiative had eight commitments with three customers at the end of 2020, but no completed installations.

[b] The original Settlement Agreement targeted 100 heat pumps. Per the end of July reforecast, this was adjusted to 50 heat pumps.

[c] Of the 78 heat pumps, 74 were installed for a large group of duplexes owned by one landlord. Duplexes are classified as single-family homes.

Table 3. 2021 Cold-Climate Heat Pump Participation and Investment

	Residential Market Rate	Income Qualified		Small Commercial	Total
		Single-Family	Multifamily		
2021 Target	50	60	333	25	**468**
2021 Installations	48	101	387	26 [a]	**562**
Percentage of Target	96%	168%	116%	112%	**120%**
2021 Investment	$320,526	$1,736,853	$2,141,112	$773,796	**$4,972,287**

[a] This is updated from the 2020-2021 Cold-Climate Heat Pump Initiatives Final Report.

In addition to persistent market barriers to the adoption of CCHPs documented in the first-year summary of pilots, the Settlement Agreement imposed eligibility restrictions for Consumers Energy CCHP initiatives, requiring heat pump systems to displace at least 50% of a customer's heating load from delivered fuels or electric resistance heating systems and limiting residential eligibility to primary residences only (i.e. secondary or vacation homes were ineligible).

Consumers Energy continued to encounter several challenges with encouraging heat pump adoption across all income levels and all residential and multifamily building types. These challenges resulted in lower participation than expected and are attributed to a lack of consumer awareness, difficulty identifying eligible customers, lack of contractor participation, and, in some cases, high incremental costs. Consumers Energy encountered fewer challenges with small business owners given that the Initiative covered the full installation cost of the CCHP, but Consumers Energy recognizes this is not a sustainable program option and expects to encounter similar challenges as the residential market when the incentive no longer covers the full equipment and installation cost for customers.

Despite these challenges, participants were generally satisfied with their experience and gave high satisfaction ratings for the overall performance of their new heat pump. Participants also reported better working equipment and increased comfort compared to their previous equipment. In addition, the Evaluation team's impact analysis for market rate and income-qualified multifamily customers show most participants will save energy, and in turn, money on their heating and cooling bills; however, the ranges of savings vary based on the heating fuel type of the replaced equipment. An engineering analysis for income-qualified single-family customers and metering analysis for small commercial customers is currently underway and will be completed by end of 2022.

Consumers Energy contracted with independent teams led by Cadmus and TRC to evaluate its respective residential and commercial program portfolios (referred to jointly as the Evaluation team throughout this report). The Evaluation team focused on providing Consumers Energy with the necessary details to inform later phases of the CCHP Initiatives and on monitoring early performance in 2021 to comply with the evaluation and reporting requirements in its Settlement Agreement.

Research Objectives

The Cadmus team focused our evaluation on providing Consumers Energy with the necessary details to inform later phases of promoting CCHPs. Following discussions with Consumers Energy's program management staff, the Cadmus team identified several research objectives regarding the evaluation.

Cadmus assessed four research objectives:

Assess the CCHP Initiatives' performance according to energy savings, customer satisfaction, impacts to customer bills, operational issues, and customer comfort.

Understand market readiness to adopt heat pump technology on a large scale and learn about the challenges of installing CCHPs.

Determine current limitations in the CCHP supply chain and their potential implications for the CCHP Initiatives.

Understand how CCHPs impact low-income customers and property managers who own income-qualified housing on non-energy factors such as changes in energy bills, heating and cooling equipment operation, and comfort levels.

Research Approach

Starting in 2021, the Evaluation team conducted several research and evaluation activities:

- Interviews with Consumers Energy CCHP Initiatives managers and implementation contractors (n=7)
- Interviews with HVAC contractors, distributors, and CCHP manufacturers (n=18)
- Billing analysis, engineering reviews, site visits, and metering for commercial participants (n=9)
- Surveys or interviews with Initiative participants and property owners (n=51)
- Residential Market Rate Participant Engineering Analysis (n=51)
- Multifamily and Income Qualified Billing Analysis (n=77 participants and 112 comparison buildings)

Participation was limited across all initiatives. This meant there were small populations to survey, interview, and perform billing analysis activities even using the census of participants. Therefore, the generated results, in most cases, are not statistically significant and while the evaluation team has made some conclusions and recommendations in this report, there is remaining uncertainty about the technology performance and market potential of CCHPs in Michigan. In addition, participation for small business customers occurred later in 2021, which delayed the metering of small business CCHPs.[3] Results from this activity will be prepared for Consumers Energy in Q4 2022.

Report Organization

We organized this report as follows:

- Summary of Key Findings, Conclusions, and Recommendations
- Contractor, Distributor, and Manufacturer Findings
- Residential Market Rate Initiative Findings
- Income Qualified Multifamily Initiative Findings
- Commercial and Industrial Cold-Climate Heat Pump Pilot Findings
- Appendices
  - Appendix A: Survey and Interview Methodology and Details
  - Appendix B: Impact Analysis Methodology and Details
  - Appendix C: Consumers Energy Heat Pump Market Rate Customer Survey
  - Appendix D: Consumers Energy Heat Pump Property Owner and Manager Interview Guide
  - Appendix E: Consumers Energy Heat Pump Multifamily Tenant Survey Guide
  - Appendix F: Consumers Energy Heat Pump Commercial Interview Guide
  - Appendix G: Consumers Energy Heat Pump Contractor Interview Guide
  - Appendix H: Consumers Energy Heat Pump Manufacturer and Distributor Interview Guide

[3] Initial impact analysis for commercial customers is reported in " 2021 Cold Climate Heat Pump Pilot Impact Evaluation Results Memo submitted to Consumers Energy by TRC. Updated cooling savings will be provided at the conclusion of additional metering in November 2022.

Summary of Key Findings, Conclusions, and Recommendations

This section presents the Evaluation team's key research findings, conclusions, and recommendations associated with the four cold-climate heat pump (CCHP) research objectives, which informed our evaluation tasks. The remaining chapters of this report provide further explanation of these findings and support for our conclusions and recommendations.

Key Findings and Recommendations

CONCLUSION 1. There is low and varied awareness of cold-climate heat pumps by homeowners, property owners and their tenants, and commercial businesses and even lower awareness that Consumers Energy offers cold-climate heat pump rebates.

Participants' awareness of CCHPs and Consumers Energy rebates was largely driven by HVAC contractors and Consumers Energy. However, awareness varied among contractors and within the territories they served. Where contractors were aware of CCHPs, they were a driving force of information dissemination about heat pumps and Consumers Energy rebates for both residential and commercial customers.

TRADE ALLIES: Contractors' overall awareness of heat pump technologies was largely correlated with the heating fuels used by their customer base. Contractors serving rural populations (where delivered fuels are more common) were more familiar with ducted heat pump systems, while contractors serving urban populations (where electric resistance heating is more prevalent) were more familiar with ductless heat pump systems. Contractors indicated that Consumers Energy could be instrumental in driving awareness of heat pump technologies, citing the success of the campaigns used to promote smart thermostats.

MARKET RATE: Most Residential Market Rate pilot participants reported being familiar with CCHPs before deciding to purchase one for their home (eight of nine), but few (three of nine) were aware that Consumers Energy provided heat pump rebates. While CCHP rebates were new in 2020, respondents' awareness of heat pumps came primarily from contractors, with about half (five of nine) indicating that a contractor had recommended a heat pump before they learned about and applied for the Consumers Energy heat pump rebate. A small number of participants (two of nine) heard about the rebate through Consumers Energy email communications.

INCOME QUALIFIED MULTIFAMILY: Multifamily property owners and managers were generally aware (31%, or n=10 of 32) of CCHPs prior to being approached by Consumers Energy, though they were not aware of Consumers Energy incentives until their involvement. However, the property owners and managers' tenants reported a lack of knowledge regarding heat pumps, with 66% of tenant respondents (n=21 of 32) saying they did not know about CCHPs, and half saying they were not aware that there was a CCHP installed in their apartment at the time of the survey. Of the half that were aware of the heat pump installation, 56% (n=9 of 16) did not know that Consumers Energy was involved in the project.

COMMERCIAL: Only two out of seven interviewed commercial respondents were familiar with cold-climate heat pump technology prior to participation. Those who had heard of cold-climate heat

pumps were unaware of the advancements in technology that made heat pumps more feasible for regions, like Michigan, with very cold winters. After learning about the new cold-climate heat pumps and Consumers Energy's pilot, most respondents were motivated to participate, but still held reservations about performance during the winter, prompting some to ask to keep their old heating system as a back-up.

RECOMMENDATIONS

High Priority: Identify opportunities for Consumers Energy to promote the cold-climate heat pump technology and incentives. Consider providing materials, such as one-page initiative summaries, for distributors to leave with contractors during their interactions. Continue to promote cold-climate heat pumps through events like the Annual Trade Ally Kickoff or identify larger distribution events or trainings where Consumers Energy can interact with trade allies.

High Priority: Increase contractor and customer education of cold-climate heat pump benefits and technology. Consider increasing the promotion of cold-climate heat pumps through planned marketing campaigns (such as bill inserts and online advertising) and through cross-program promotions.

CONCLUSION 2. Because natural gas is the predominate heating fuel in Michigan, and current Michigan Public Service Commission policy limits fuel-switching, there are limited cost-effective cold-climate heat pump installation opportunities. This contrasts with other states such as Maine and Vermont where a higher percentage of homes use more costly heating fuels such as propane and oil and where state policies incentivize fuel-switching.

TRADE ALLIES: While demand is increasing, trade allies reported that multiple barriers have limited demand for CCHPs in Michigan compared to other states. Manufacturers and distributors noted that awareness of and affinity for CCHPs among contractors varied and some maintain the belief that heat pumps are not effective in cold climates. Contractors and distributors also reported that increased customer awareness would help increase adoption; however, the cost of new CCHPs remains prohibitive. A homeowner likely needs to financially benefit from switching to a CCHP to be interested, but the lifecycle cost of a new CCHP compared to alternative heating technologies supplied by natural gas (the predominate heating fuel in Michigan) likely does not financially benefit the homeowner at a time when natural gas rates are low. Contractors acknowledged this fuel-switching challenge and said that even when they identify a potential cold-climate heat pump customer, there are few tools available for the contractor or customer to make accurate projections of the total system lifetime cost savings.

MARKET RATE AND COMMERCIAL CUSTOMERS: During 2021 and 2022, the Michigan Public Service Commission allowed Consumers Energy to target market rate and commercial customers who receive non-regulated fuels and those with electric heating systems. Consumers Energy's *2018 Residential Appliance Saturation and Home Characteristics Study* found that approximately 82% of customers in single-family homes across Consumers Energy's natural gas, electric and combination fuel

service territory heat their homes with natural gas, while 4% use electric heat and 14% use another source such as propane, fuel oil, or wood. This heating fuel distribution creates a significant challenge with identifying homeowners and businesses that may be eligible for a CCHP under the current regulatory rules (i.e., heat their homes or buildings with electric or distributed fuels), and limits market potential. Of the residential market rate participants for which baseline analysis was conducted (n=51), the majority (59%) used propane or oil, while 31 % used electric heat and 10% used natural gas heat prior to installing their heat pump[4].

Four of the seven commercial respondents interviewed discussed wanting to move away from using propane, and two of the respondents were motivated to participate in the pilot specifically so they could stop using propane. While respondents appreciated the opportunity to move from propane to electric heating, it is unclear whether Consumers Energy can continue with this targeted approach beyond the pilot phase. Future negotiations between the Michigan Public Service Commission and Consumers Energy and its stakeholders will determine whether Consumers Energy can continue to rely on this targeted approach in future initiative cycles.

RECOMMENDATIONS

High Priority: Because contractors reported that it is not always simple to determine when cold-climate heat pumps are economically more beneficial than traditional equipment, provide them with sales tools, such as a cost-effectiveness calculator, that can assist them in identifying when a cold-climate heat pump makes financial sense for their customers.

Low Priority: Promote the space cooling benefits associated with a cold-climate heat pump. Cold-climate heat pumps are a good option to add cooling where there was not previously a whole-home space cooling system or where the cold-climate heat pump can replace inefficient central air conditioners and room air conditioners.

CONCLUSION 3. Participants were generally satisfied with their experience and gave very high ratings for the CCHP Initiatives offering. However, multifamily tenants' satisfaction was split, largely based on whether the tenant received education on how to operate the new equipment.

MARKET RATE: Market rate customers gave high satisfaction ratings, with all nine respondents giving a rating of 8 or higher for their overall experience with the heat pump. In addition, market rate customers were highly likely to recommend the heat pump to a friend (with a net promoter[5] score of +89).

[4] Consumers Energy excluded most customers that used natural gas for space heating from the CCHP initiative, but a small number of participants recruited by contractors used natural gas prior to installation of the CCHP.

[5] The net promoter score is expressed as an absolute number between -100 and +100 that represents the difference between the percentage of promoters (respondents giving a rating of 9 or 10) and the percentage of detractors (respondents giving a rating of 1 to 6).

INCOME QUALIFIED MULTIFAMILY: The three interviewed income qualified multifamily property owners and managers provided an average rating of 9.5 (on a 10-point scale) for their satisfaction with the CCHP Initiatives and their likelihood to recommend heat pumps to a colleague. The property owners and managers also rated their likelihood to adopt similar CCHP equipment in their other properties as a 9.0 on a 10-point scale.

Income-qualified multifamily tenants (n=23 of 32) were *very satisfied* with their CCHP experience, and generally felt that the heat pumps provided improved winter heating and summer cooling comfort. Multifamily tenant participants gave an average rating of 8.7 for their overall experience with the heat pump, though some may not have been aware of their heat pump until they were contacted for the survey. Respondents also gave an average rating of 8.8 regarding summer comfort and 7.9 regarding winter comfort. However, tenants' willingness to recommend Consumers Energy was dependent on the level of communication and instruction provided to them regarding equipment operation. Tenants who provided verbatim feedback around lack of instruction were more likely to provide a lower overall net promoter score (averaging +13) than those who received instructions (averaging +50). Similarly, tenants who reported that the installer did not set up their heating and cooling schedule were also more likely to provide a lower overall net promoter score (averaging +10) than those who had the installer set up a schedule (averaging +67).

COMMERCIAL: Commercial participants rated their overall satisfaction with the CCHP Initiatives as an average of 9.9 out of 10, and 86% (six out of seven interviewees) strongly agreed that Consumers Energy made it easy to participate in the initiative.[6] In follow up interviews with participants, four out of five interviewees reported being satisfied with their heat pump's performance during the winter.[7]

CONCLUSION 4. Some participants received a new thermostat with their CCHP. Participants who received a new thermostat had varied knowledge about how to use it to optimize operation of their heat pump and some could have benefitted from additional instructions and training.

MARKET RATE: Seven of the nine residential market rate participants had a programmable or smart thermostat, while two reported having a non-programmable thermostat. Of those who had a programmable thermostat, only two programmed temperature setbacks. Despite most having thermostat programming capability, four of nine tended to adjust the temperature manually.

INCOME QUALIFIED MULTIFAMILY: Only three income qualified multifamily respondents could confirm with certainty that the contractor set up a heating and cooling schedule for their heat pump. These three participants also confirmed that the heating and cooling schedule set up by the

[6] Commercial participants were interviewed prior to experiencing a full heating season and some respondents listed this uncertainty about how the equipment would perform during the heating season as a reason for not giving a higher satisfaction rating for their heat pump, though the average rating was still 9.3 out of 10.

[7] The one respondent who was displeased, noted that the heat pump took a while to turn on, they often felt a cool breeze that was discharged directly onto an employee, and they had to adjust their thermostat higher than usual in order to achieve their preferred temperature.

contractor was still in operation. Only 25% (n=8) reported receiving instructions or documentation about the heat pump or use of their thermostat with the heat pump.

COMMERCIAL: Most respondents needed additional time to learn how to use their new thermostats and a few had minor issues operating their heat pumps. While most respondents did not have any problems with their new heat pumps, some (43%; n=3) reported that learning how to use their new thermostat was the most challenging aspect of their new equipment. Two respondents (29%) also reported needing a contractor's assistance with minor issues related to operating their heat pump. These minor issues included resolving an installation error and adjusting the cooling so that the air temperature was reaching the thermostat's temperature setpoint. Another finding from the follow up interviews was that some customers needed additional support understanding the controls and settings of the heat pumps to maximize the value, especially when sites have overlapping building controls with multiple heating units.

RECOMMENDATION

High Priority: Consider increasing follow up communications and support after the installation to ensure participants understand their new technology. Sending follow-up emails with resources and providing high-touch support after the installation engenders a positive equipment experience, which is critical for word-of-mouth testimonial marketing. Encourage contractors to provide set up and programming instructions and provide contractor training to ensure they are familiar with different types of thermostats and systems.

CONCLUSION 5. Participants reported better working equipment and increased home and business comfort levels after the installation of their CCHP.

MARKET RATE: Most market rate participants surveyed (seven of nine) said their home was more comfortable after installing the heat pump. The nine respondents rated their comfort level as 9.1 on average during the summer, with a slightly lower rating of 8.6 (n=5) during the winter. None of the respondents indicated any concerns with the heat pump's ability to heat to a preferred comfort level. Five respondents also mentioned improved heating and cooling distribution across sections of the home.

INCOME QUALIFIED MULTIFAMILY: Income-qualified multifamily tenants said their homes were as comfortable with the CCHPs as before (43%), with one-quarter reporting increased comfort levels. A few tenants said their home was too hot or too cold after the heat pump installation. Property owners and managers indicated that tenant comfort was a key decision factor to install CCHPs.

COMMERCIAL: Customers were very satisfied with heat pump performance overall , though three interviewees (43%) reported some minor initial issues with their heat pumps, including one who said it did not cool down to the expected temperature and two who had issues with the installation that required a contractor to fix.

RECOMMENDATION

Medium Priority: Promote the increased home and business comfort that cold-climate heat pumps can provide during both the heating and cooling seasons. Developing and using home and business testimonials could be an effective way Consumers Energy can promote the benefits of cold-climate heat pumps such as increased comfort, lower energy bills, and for some, the addition of space cooling.

CONCLUSION 6: Distributors generally had heat pump inventory on hand, so delivery times were either not impacted or were only impacted temporarily by manufacturing delays.

While manufacturers and distributors reported manufacturing delays as a result of COVID-19, as well as on-going transportation delays, distributors generally reported having sufficient stock on hand to meet current demand. Only one distributor reported a delay (6 to 8 weeks) in getting equipment to the customer. Note that custom equipment was generally not discussed in the interviews with manufacturers and distributors, and it is possible that timelines for custom equipment could be different. It is also worth noting that the manufacturer and distributor interviews were conducted in April of 2021, and the factors influencing supply chains may have changed since this time.

CONCLUSION 7: Most residential market rate and income-qualified Multifamily participants realized heating and cooling utility bill savings after the installation of their CCHP. However, bill savings largely depends on heating fuel prior to the heat pump installation, as well as how the homeowner used their new equipment.

MARKET RATE: The majority of market rate participants replaced propane heating systems (51%), followed by electric heating (31%), natural gas heating (10%), and fuel oil heating (8%).[8] Based on engineering estimates, market rate participants who replaced propane or electric heating systems will realize approximately $910 to $1,680 in heating and cooling savings per year[9]. The five homes that previously heated with natural gas will likely see an increase in their utility bill of $450 per year on average due to the higher cost of electricity compared to natural gas; also, four of the five homes did not have existing central air conditioning, which means they will add electrical load in the summer.

INCOME QUALIFIED MULTIFAMILY: Income-qualified multifamily tenants, even though retaining their original baseboard heating systems, experienced annual savings of 896 kWh, which translates to approximately $147 in annual bill savings. Most of the savings (93%) were realized during the heating season (largely October-April). These savings during the heating season were equivalent to approximately 23% of baseline weather-sensitive electric heating use. Income qualified multifamily tenants experienced lower than anticipated savings attributable to the heat pumps because they continued use of their baseboard heating systems, consistent with other recent evaluation findings.

[8] At the time of conducting the engineering analysis the evaluation team had a sample of 51 CCHP installations.

[9] Based on fuel costs at the time of the analysis in January 2022.

INCOME QUALIFIED SINGLE FAMILY: Due to low participation and delays due to COVID, the Income Qualified Single-Family Impact analysis will be completed in 2022. The Evaluation team is currently conducting an engineering analysis of the impacts for the income-qualified single-family installations, relying on MEMD parameters and assumptions collected from customers such as home vintage, presence of central cooling, equipment efficiencies, tonnage, and other data. The analysis will be completed later in 2022 and filed in the case docket.

COMMERCIAL: Because participation in the small business pilot occurred later in 2021, the impact evaluation was delayed. The impact evaluation is based on metered data, and TRC is keeping the meters in place to collect data for at least one complete heating season and one complete cooling season for each site.[10] The results of the heating season impact analysis are presented in a separate memo that is included in the filing of 2021 studies made on August 31, 2022.[11] Metering for the 2022 cooling season is still in progress as of the writing of the report, and analysis will take place in later in 2022.

RECOMMENDATIONS

High Priority: Provide multifamily property owners who had cold-climate heat pumps installed with information for how continued use of baseboard heating systems will minimize the tenant's ability to achieve the highest potential heating, and cost savings.

High Priority: Provide multifamily property owners with handouts they can distribute to tenants with simple operational instructions to ensure all new tenants understand how to operate their heat pump systems. Additional follow up and coordination with maintenance staff to review proper operations would ensure persistence of heat pump savings.

High Priority: If the Michigan policy on fuel switching should change, natural gas heating customers should be screened prior to approval to ensure the heat pump has potential to reduce energy bills.

Table 4 shows the Evaluation team's conclusion for each research objective outlined above.

[10] Metering analysis was performed for 22 CCHP installations.

[11] TRC. 2022. C&I 2021 Cold Climate Heat Pump Pilot Impact Evaluation Memo

Table 4. Research Objective Mapping

Conclusion	Research Objective			
	1. Assess Cold-Climate Heat Pump Initiative Performance	2. Understand Market Readiness and Challenges	3. Determine Current Supply Chain Limitations	4. Understand Impacts on Low-Income Customers
There is low and varied awareness of cold-climate heat pumps by homeowners, property owners and their tenants, and commercial businesses and even lower awareness that Consumers Energy offers cold-climate heat pump rebates.		✓		
Because natural gas is the predominate heating fuel in Michigan, and current Michigan Public Service Commission policy limits fuel-switching, there are limited cost-effective cold-climate heat pump installation opportunities. This contrasts with other states such as Maine and Vermont where a higher percentage of homes use more costly heating fuels such as propane and oil and where state policies incentivize fuel-switching.		✓		
Participants were generally satisfied with their experience and gave very high ratings for the Cold-Climate Heat Pump Initiatives offering. However, multifamily tenants' satisfaction was split, largely based on whether the tenant received education on how to operate the new equipment.	✓			✓
Some participants received a new thermostat with their cold-climate heat pump. Participants who received a new thermostat had varied knowledge about how to use it to optimize operation of their heat pump and some could have benefitted from additional instructions and training.		✓		
Participants reported better working equipment and increased home and business comfort levels after the installation of their cold-climate heat pump.	✓			✓
Distributors generally had heat pump inventory on hand, so delivery times were either not impacted or were only impacted temporarily by manufacturing delays.			✓	
Most residential participants realized heating and cooling utility bill savings after the installation of their cold-climate heat pump. However, bill savings largely depends on heating fuel prior to the heat pump installation, as well as how the homeowner used their new equipment.	✓			✓

Recommendation Priority

To assist Consumers Energy in prioritizing the actions needed to address these recommendations, the Evaluation team organized each evaluation recommendation by topic and prioritized them based on the following definitions.

- ***High Priority:*** The evaluation revealed compelling and conclusive data on a concern or a current initiative strength that are likely to have a significant impact on customer satisfaction, achievement of participation goals, or initiative savings if not addressed or maintained.
- ***Medium Priority:*** The evaluation revealed data that are inconclusive and require additional investigation or the issue is likely to have a moderate impact on initiative effectiveness or efficiency.
- **Low Priority:** The issue is likely to have little impact on initiative effectiveness or efficiency.

Table 5 lists the CCHP initiatives evaluation recommendations.

Table 5. Summary of Heat Pump Pilot Recommendations and Priorities

Priority	Summary of Recommendations
High Priority	Identify opportunities for Consumers Energy to promote the Cold-Climate Heat Pump technology and incentives. Consider providing materials, such as one-page initiative summaries, for distributors to leave with contractors during their interactions. Continue to promote cold-climate heat pumps through events like the Annual Trade Ally Kickoff or identify larger distribution events or trainings where Consumers Energy can interact with trade allies.
	Increase contractor and customer education of cold-climate heat pump benefits and technology. Consider increasing the promotion of cold-climate heat pumps through planned marketing campaigns (such as bill inserts and online advertising) and through cross-program promotions.
	Because contractors reported that it is not always simple to determine when cold-climate heat pumps are economically more beneficial than traditional equipment, provide them with sales tools, such as a cost-effectiveness calculator, that can assist them in identifying when a cold-climate heat pump makes financial sense for their customers.
	Consider increasing follow up and support after the installation to ensure participants understand their new technology. Sending follow-up emails with resources and providing high-touch support after the installation engenders a positive equipment experience, which is critical for word-of-mouth testimonial marketing. Encourage contractors to provide set up and programming instructions and provide contractor training to ensure they are familiar with different types of thermostats and systems.
	Provide multifamily property owners who had cold-climate heat pumps installed with information for how continued use of baseboard heating systems will minimize the tenant's ability to achieve the highest potential heating and cost savings.
	Provide multifamily property owners with handouts they can distribute to tenants with simple operational instructions to ensure all new tenants understand how to operate their heat pump heating systems. Additional follow up and coordination with maintenance staff to review proper operations would ensure persistence of heat pump savings.
	If the Michigan Public Service Commission policy on fuel switching should change, natural gas heating customers should be screened prior to approval to ensure the heat pump has potential to reduce energy use.
Medium Priority	Promote the increased home and business comfort that cold-climate heat pumps can provide during both the heating and cooling seasons. Developing and using home and business testimonials could be an effective way Consumers Energy can promote the benefits of cold-climate heat pumps such as increased comfort, lower energy bills, and for some the addition of space cooling.
Low Priority	Promote the space cooling benefits associated with a cold-climate heat pump. Cold-climate heat pumps are a good option to add cooling where there was not previously a whole-home space cooling system or where the cold-climate heat pump can replace inefficient central air and room air conditioners.

Contractor, Distributor, and Manufacturer Findings

Consumers Energy launched the CCHP initiatives just prior to the start of the COVID-19 pandemic, which as reported by Consumers Energy staff, created unique challenges such as long delays in project timelines due to back-ordered equipment. In addition, trade ally participation was low, with only one trade ally completing the vast majority of installations across these offerings in the early months of the initiative. To determine the sources of these barriers and understand the challenges associated with adopting CCHPs in Consumers Energy's service territory, the Evaluation team interviewed eleven contractors, two manufacturers, and five distributors involved in the installation, production, and distribution of CCHPs in Michigan.

Contractors' awareness and perceptions of CCHPs varied, and a contractor's interest in heat pump technologies in general depended largely on the availability of different heating fuels in their service territories. Contractors in rural areas, where delivered fuels are more common, had more awareness of and a greater affinity for ducted systems and heat pumps in general. Contractors in urban areas had more awareness of ductless systems, but overall lower levels of familiarity with and affinity for heat pump technologies.

Among all contractors, the pervading theme regarding CCHPs (and heat pumps in general) is that of uncertainty. In order to confidently promote heat pump technologies, contractors must be able to determine the operating cost of the equipment compared to a customer's existing equipment. Currently, there are no readily available tools that allow contractors to accurately model and compare the energy consumption of a heat pump to other heating sources; combined with the comparatively higher up-front cost of heat pumps, this inability to accurately model potential energy savings commonly makes heat pumps a non-starter. Furthermore, several contractors expressed a hesitancy to promote electric heating sources to their customers, as they perceived the price of electricity to be less static and more prone to price increases than other fuel sources. Additionally, some contractors were unaware that CCHPs were effective in cold climates. The confluence of uncertainty around CCHPs is commonly too significant of a barrier for contractors to abandon the status quo of a like-for-like equipment replacement.

Although there were manufacturing and transportation delays, distributors reported having stock on hand that was sufficient to meet current demand. Manufacturers and distributors noted that some contractors maintained the belief that heat pumps were not effective in cold climates (a finding that may be correlated with a contractor's location, given that the contractor interviews found that contractors in urban areas were less aware and less in favor of heat pumps compared to those in rural areas). Aside from this contractor barrier, manufacturers and distributors pointed to customer hesitation due to large up-front or long-term costs associated with CCHPs. In Michigan, CCHPs are less cost-effective than in other states due to the low cost of natural gas, but demand seems to be increasing, especially in rural areas where homes are predominantly heated with propane or oil.

This chapter provides contractor findings separately from manufacturer and distributor findings.

Contractor Findings

The Evaluation team interviewed eleven HVAC contractors to address three research objectives:

- Determine current awareness and perceptions of heat pump technologies.
- Identify the main barriers to installing heat pumps in Michigan.
- Identify marketing and outreach best practices.

The key findings corresponding to each research objective are outlined below.

Cold-Climate Heat Pump Awareness and Perceptions

Contractors' overall awareness of and attitudes toward CCHP technologies were largely correlated with the type of fuel available to the contractor's customer base. Contractors serving rural populations were more familiar with ducted systems, displayed an overall greater affinity for heat pump technologies, and reported higher levels of customer awareness and demand. Conversely, contractors serving urban populations were more familiar with ductless systems and displayed comparatively lower levels of familiarity with improvements in CCHP capabilities.

Contractors indicated that general awareness of heat pump technologies among customers was low but increasing. Contractors reported a marginal increase in the number of customers asking for the technology in recent months, and a more substantial increase in customers who were aware once the contractor presents CCHPs as an option. Similarly with contractor awareness, customer awareness is largely correlated with location and the availability of natural gas.

> "The typical customer is not aware it [CCHPs] is a heating option."
> - Contractor

Best Cold-Climate Heat Pump Applications

Contractors detailed the various scenarios in which CCHPs are currently being adopted by customers, or where they make the most sense for future adoption. For ducted systems, contractors reported the three best applications:

- Customers with propane or delivered fuels who have no access to natural gas
- Green-motivated customers who are not as cost conscious
- New construction

The best applications for ductless mini splits differ by heating versus cooling:

- Heating
  - Customers with electric baseboard heat—especially multifamily customers
  - Customers with hot or cold spots not served well by the existing system (and who could use heat pumps for supplementary heat)
- Cooling
  - Customers with no existing duct work (such as those with a boiler or electric baseboard heat)
  - Commercial applications, such as computer server rooms or elevator rooms
  - Vacation homes (that are not occupied in the winter)[12]

[12] Note that secondary or vacation homes were not eligible for the pilot.

Barriers to Adoption

Contractors provided a variety of reasons for the relatively slow adoption of heat pump technologies to date. Barriers primarily relate to financial constraints, either the up-front cost of the equipment or the comparatively higher operating cost (where natural gas is available). Adding to concerns over the operating cost is the idea that electric rates can be somewhat variable, so even if a contactor is able to project the operating cost of equipment for their customer, there is no guarantee that the projection will be accurate in the future. Furthermore, even when projecting operating costs using a fixed cost of electricity, there are no readily available tools by which contractors or customers can make accurate projections of the total system cost (equipment and operation). Several barriers were identified:

- Higher equipment cost versus other systems
- Relative higher cost of electricity compared to natural gas
- Variability in electric rates
- Inability to make accurate comparisons between the operating costs of CCHP systems to traditional heating systems
- Lack of education and awareness for the public and contractors alike
- Contractor perceptions of poor performance in the Michigan climate (less common)

Installation complexity and cost, supply chain robustness, and previous experiences with heat pumps are not seen as barriers among contractors. Contractors detailed how heat pumps generally require minimal additional work compared to traditional systems, and that relative to the additional cost of the equipment itself, the additional installation costs are negligible.

> "ASHPs [air-source heat pumps] have fallen off [become less common] for a couple reasons: most homes lately have a natural gas option, so we feel it is more to their advantage to use the gas furnace than air-to-air heat pumps."
>
> - Contractor

Overcoming Barriers to Adoption

There was no consensus among interviewed contractors as to what would be most influential in increasing CCHP adoption. Two contractors referenced a different rate structure for customers who use electric heat: Consumers Energy used to offer a special rate for customers with electric heat, and one contractor said the number of heat pumps they install has decreased since this rate was rescinded. These contractors believe that introducing an electric heating rate would potentially help to price CCHPs more similarly to natural gas–fired systems and lead to increased adoption:

- "If you choose a certain heating system, they used to offer a heating energy price decrease. If Consumers [Energy] could bring something like this back, demand would explode. Offer special rates for HP [heat pump] use for heating."
- "Used to do heat pumps more when they offered an electric heating rate, but we've switched to mostly natural gas due to cost of use."

Two contractors indicated that additional customer education is necessary to increase CCHP adoption, with one proposing a potential marketing campaign similar to the thermostat promotions that Consumers Energy currently offers. Other suggestions included offering increased rebates and a tool that helps customers more accurately project the lifetime operating costs of heat pumps against other space heating options:

- "Messaging would be a big bonus for all the contractors. It would help with promoting them [CCHPs]. Like the thermostat promotions that have produced a lot of positive feedback, [a campaign promoting heat pumps] would be very helpful."
- "Just educating people about that they've gotten the bugs out of these things [CCHPs] and they're working great."
- "Better rebates on them [CCHPs] for sure. With the [heat pumps] we have had a hard time meeting Consumers Energy's rebate requirements to qualify; our basic ASHP [air-source heat pump] doesn't qualify [and would] need to get up into the second or third level of efficiency, and with the increased cost the low [$100] rebates are not effective."
- "[It would be great] if Consumers [Energy] were able to come up with a tool comparing purchase and operational costs of electricity versus natural gas systems, showing savings of switching over when customers have dual fuel systems."

Marketing and Outreach Suggestions

As previously noted, two contractors said that increased customer education would be the most impactful way to increase customer demand for CCHP technologies. Each interviewed contractor suggested specific comparisons or promotional strategies to present the equipment to customers:

- Two suggested direct promotional campaigns from Mitsubishi that have been successful within Michigan
- One suggested using smart thermostat promotions from Consumers Energy
- One suggested promoting heat pumps as an air conditioner (AC) that also provides free heat
- One suggested offering a winter electric heating rate for owners with a CCHP
- One suggested providing tools to demonstrate savings compared to other systems

Income-Qualified Considerations

Two contractors indicated that unique circumstances may prevent the widespread adoption of heat pumps for income-qualified customers:

- The potential for theft of the costly units
- Low-income property managers' aversion to potential equipment issues and ensuing repairs

Distributor and Manufacturer Findings

The Evaluation team interviewed five distributors and two manufacturers of CCHPs in Michigan to address several research objectives:

- Confirm and document the supply chain for CCHPs in Michigan
- Identify the barriers leading to extended timelines for CCHP installation
- Identify sources of differences in CCHP installation costs across states
- Explore the cause of low participation by trade allies
- Identify any additional barriers and challenges delaying the widespread adoption of CCHPs in Michigan, like training or education
- Identify ways in which Consumers Energy can influence market adoption

The key findings corresponding to each research objective are outlined below.

Cold-Climate Heat Pump Supply Chain

Manufacturers and distributors confirmed that CCHPs follow a traditional supply chain structure, with no difference compared to traditional air-source heat pumps (ASHPs) or other types of HVAC equipment. While this typically means that units move from the manufacturer to the distributor and then to a contractor before reaching customers, there are exceptions for national corporate customers, who may purchase equipment directly from a distributor rather than through a contractor (see Figure 1).

Many CCHPs are manufactured abroad and shipped to ports in the United States, primarily to California or Georgia, before being trucked to regional destinations.

Figure 1. Heat Pump Supply Chain

Installation Timelines

Distributors reported it takes from one to 20 weeks to receive inventory from manufacturers, depending on whether the manufacturer is overseas or domestic and whether they placed a rush order. Manufacturers and distributors reported experiencing manufacturing delays as a result of COVID-19, as

well as ongoing transportation delays that included backups at ports and a truck driver shortage that began in 2018, prior to the pandemic.

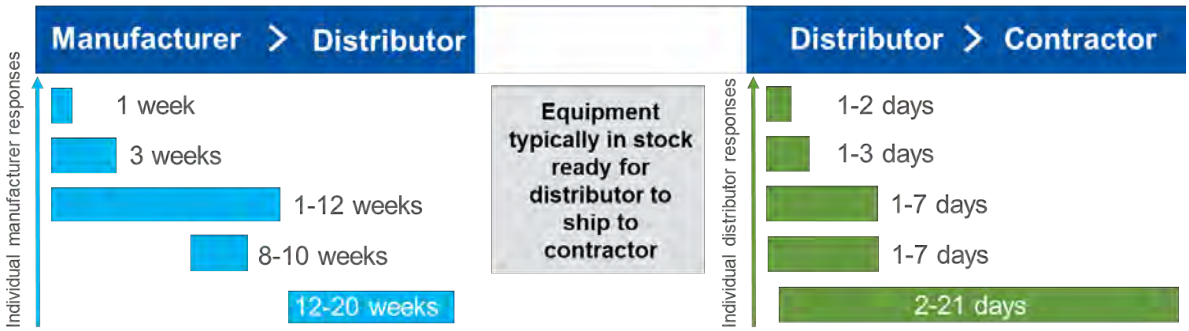
Despite manufacturing and transportation delays, distributors generally reported having stock on hand, so installation times were either not impacted or were only impacted temporarily. For the most part, distributors had learned how to manage around these constraints by being proactive and front-loading inventory. With enough inventory in stock, they can prevent delivery delays from impacting installation timelines:

- "With COVID-19, a lot of the supply chains have been broken. We were very responsive and proactive this year by buying up huge amounts of inventory. If we were to stop purchasing equipment now (March 2021), we would have enough equipment to last through November." – Distributor
- "This whole COVID thing really threw a wrench in a lot of this, and so I think a lot of it, the success that we have seen, having a little bit of inventory in Michigan, has to be to the credit of the distributor being proactive." – Manufacturer

When distributors have stock on hand, they reported that they typically deliver equipment to the contractor within one week, as shown in Figure 2. For a custom system or for equipment not in stock, the delivery timeline can stretch to three weeks or more, and one distributor had seen delays reach as long as six to eight weeks at points earlier in the pandemic, saying, "Much like everything else in the world, COVID really wreaked some havoc on manufacturing, so you know there were some times when it was six to eight weeks, but thankfully with good planning, we had enough stock that we really didn't have to deal too much with it [delays]." One distributor stated that custom equipment requires roughly 30 days to get to the contractor. Note that with the exception of this one distributor, timelines for custom equipment were not discussed in the interviews. It is possible that timelines for custom equipment could be different.

Notably, manufacturers and distributors have not observed any issues with the supply chain or with installation timelines that are unique to CCHPs or to Michigan.

Figure 2. Equipment Delivery Timelines Reported by Distributors



Note: The range in times for equipment to be delivered from the manufacturer to the distributor is due to differences between oversees versus land shipping and rush versus standard orders. One distributor also noted that COVID-19 led to six- to eight-week delays in equipment getting from the distributor to the contractor.

Cold-Climate Heat Pump Cost Differences across States

Most interviewed distributors and manufacturers did **not** report CCHP cost differences between Michigan and other states. One exception was a distributor who reported that installation costs in Michigan are higher compared to the Northeast. The distributor linked this difference to lower familiarity among installers in Michigan and said they expect costs to go down as installers become more familiar with the technology.

Within Michigan, interviewees observed differences in cost based on location in the state, with labor costs in urban areas being higher than costs in more rural areas. As one distributor stated, "Michigan prices are pretty average compared to Ohio [prices]. If you're in a more rural area, installation prices tend to go down, and if you're in a bigger, more metropolitan area then prices tend to go up."

One manufacturer also pointed out cost differences depending on whether contractors are union or non-union: "We go from $85 an hour that a contractor will charge a consumer to $140, especially if they are [in] a union. Or [when] you get into the Motor City, they seem to think they can charge a lot more."

Four of the five distributors reported increased CCHP costs over the last six months, and two interviewees noted that the cost of materials is rising—particularly for sheet metal, steel, and copper—which could lead to further cost increases down the road. As one distributor said, "[Internal costs] are going through the roof, [and] manufacturers can't eat it all."

Contractor Engagement

All five of the interviewed distributors shared the perception that there are still contractors in Michigan who do not have a full understanding of CCHPs and need to become more familiar with the technology and benefits. All five distributors also reported offering trainings to contractors to further their knowledge of CCHPs, including installation and service trainings as well as sales-oriented trainings: "We do training at every level possible, from technical service/installation to sales, and we have even offered business training."

Reports of attendance at trainings varied, with three who said their trainings were well-attended, one who said there was a mix of well-attended and less well-attended trainings, and another who said they were not well-attended, which they attributed to a lack of awareness of CCHP technology. One distributor also reported that, in their experience, one-on-one trainings work better than trainings offered in a group setting. Many training offerings have been moved to virtual platforms like Zoom due to the pandemic, which two distributors noted has been more challenging than in-person trainings.

Interviewees noted that trainings do not differ by state, e.g., they do not address specific climate, available programs, or current policies.

Barriers to Adoption

Four distributors mentioned that one barrier to CCHPs becoming more common in Michigan is that awareness of and trust in CCHP technology is not yet widespread among contractors in the state.

Instead, they reported that many contractors continue to hold an outdated perception that heat pumps are not a viable option in cold climates:

- "A lot of the contractors, especially a lot of the old timers... They don't see heat pumps as a viable option in Michigan. We hear that so many times." – Distributor
- "As technology continues to get better and heat pumps can operate at lower temperatures, you're always going to have an old service tech or installer that absolutely does not believe in the new technology." – Distributor
- "A lot of contractors are not as informed as they could be." – Distributor

Other barriers mentioned include concerns about up-front and long-term costs and, relatedly, the lack of incentives (since current policies in Michigan do not allow utilities to incentivize customers to switch from natural gas heat to electric heat).

Interviewees reported that demand for CCHPs is higher in other states than in Michigan. One attributed this lower demand in Michigan to the lack of widespread understanding among contractors and customers that heat pumps can be effective in cold climates. Others discussed the trade-offs in switching from different fuel sources. One distributor pointed out that natural gas is cheaper in Michigan than in other states, making CCHPs less cost-effective, and therefore less appealing, for those who currently use natural gas heating.[13] For those who use more expensive propane or fuel oil systems, however, distributors felt switching to a heat pump *would* be more cost-effective: "All-electric heat is a no-brainer. If they have propane or fuel oil, [heat pumps] make sense. With a natural gas system, it is a tougher sell."

Overcoming Barriers

Although interviewees reported that demand for heat pumps is lower in Michigan than elsewhere, they have also observed that demand in the state is increasing. Two distributors reported seeing major growth in CCHP adoption in recent years: one reported that their 2021 quarter 1 CCHP sales were greater than CCHP sales in the previous two years combined, and another reported having record demand in 2020, with sales doubling from 2019.

> "Ductless mini-splits are a huge, growing market, [with] the largest growth potential of any [technology], and everyone is saying the same thing."
>
> - Distributor

While there are still awareness and education gaps, interviewees reported that contractors and customers are becoming increasingly familiar as CCHPs have become more technically viable. As mentioned above, CCHPs are also increasingly *economically* viable in rural areas where there is a reliance on propane and oil heat.

[13] The proportion of households in Michigan with natural gas heating (82%) is higher than in most other states (Consumers Energy. 2018 Residential Saturation Study. Not available online).

The two biggest tools that interviewees noted as key to increasing CCHP adoption are incentives and increasing contractor and customer education. Several distributors emphasized that incentives and rebates are highly appealing to customers, making them an important tool for increasing adoption:

- "Customers would be willing to switch with an incentive." – Distributor
- "Incentives help to drive adoption." – Distributor

> "[It's] all about making the contractors aware of the benefits."
> – Distributor

Contractor education is also seen as a need, both to increase awareness of the viability of CCHPs in the state and to improve contractors' understanding of the benefits and cost-effectiveness of CCHPs.

Increasing Adoption

Distributers and manufacturers mentioned that Consumers Energy has been actively working to increase CCHP adoption, and they see the role of utilities as critical in helping this new technology gain a foothold.

> "The role of the utility is very important because they are the ones that can accelerate the [adoption of CCHP] technology."
> – Distributor

Distributers and manufacturers suggested that Consumers Energy can further encourage adoption in three ways: through education and training, by providing sales tools, and by offering incentives. Additional education and marketing directed at customers is needed to increase their awareness of the benefits of CCHPs.

> "There is a lack of information about the difference between costs for gas and electric."
> – Distributor

Similarly, interviewees suggested providing in-person trainings to contractors about rebates and the benefits of CCHP technology, including targeted trainings for technicians who may need more help to transition to a new technology. Three interviewees also said it would be useful to have a calculator tool that helps contractors easily demonstrate cost savings for switching to CCHP technology.

Interviewees also suggested that higher incentives would be instrumental in increasing CCHP adoption, and primarily felt that incentives should be offered via a midstream strategy. While one interviewee said rebates should be directed to contractors, all the other interviewees suggested that rebates should be directed to distributors, with one saying it would be helpful to have automatic incentives that minimize paperwork. One interviewee also suggested that incentives should be provided for CCHPs that have equivalent seasonal energy efficiency ratio (SEER) ratings as incentivized air conditioners.

> "Utility rebates really help. In some cases, the rebate has been able to cover the difference [between an AC and a heat pump]."
> – Distributor

Residential Market Rate Initiative Findings

In November 2021, the Evaluation team sent a survey invitation to 29 Residential Market Rate pilot participants who had valid emails. The email survey invitation included a $15 incentive for taking the survey. Nine of the 29 participants completed the survey, for a 31% response rate; with such a small sample size, the results should be interpreted with caution and only viewed as directional indications (not intended to be analyzed with statistical confidence).

In addition to the participant survey, the Evaluation team conducted an engineering analysis to determine market rate CCHP participants' energy and utility bill cost savings. The Evaluation team used data collected from the Consumers Energy initiative team and calculations that can be found in the *Michigan Energy Measures Database* (MEMD).[14]

This chapter first provides details of Residential Market Rate pilot participants, then covers the engineering analysis findings.

Market Rate Participant Survey

The Evaluation team designed the participant survey to address several key objectives:

- Assess awareness of and motivation for installing heat pumps
- Assess the participant installation experience
- Document perceptions of heat pumps, energy or cost savings, and comfort levels
- Document participant usage behavior
- Assess satisfaction with the offering and with Consumers Energy

Awareness and Motivation

All nine respondents confirmed that they received a rebate for their heat pump and that they were present when the heat pump was installed. While most (eight of nine) were familiar with heat pumps before deciding to purchase one for their home, few (three of nine) were aware that Consumers Energy provided heat pump rebates (Figure 3). Respondents first learned about Consumers Energy's heat pump rebate primarily through their contractor (four of nine) or from a Consumers Energy email (two of nine). About half (five of nine) said a contractor had recommended a heat pump before they learned about and applied for the Consumers Energy heat pump rebate.

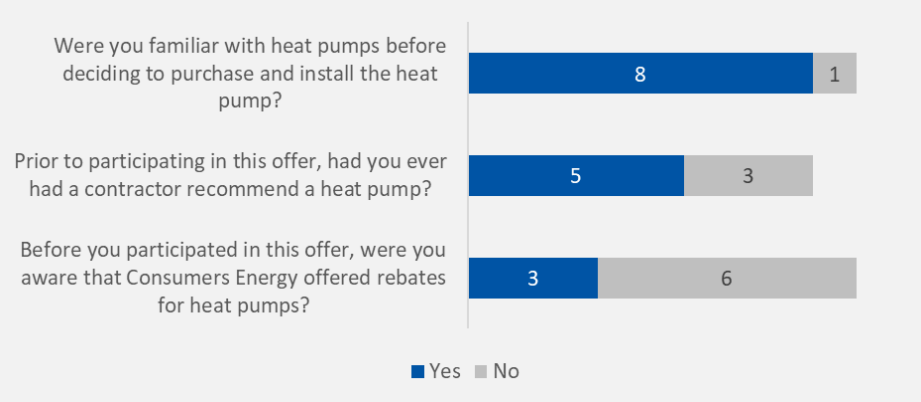
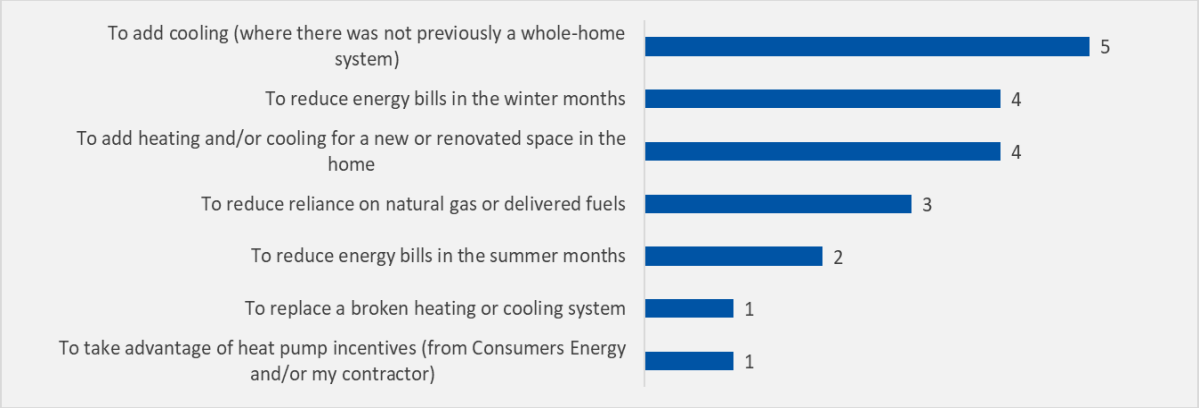
Figure 3. Heat Pump Awareness



Source: Heat Pump Market Rate Customer Survey Questions B3, B4, and B5 (n=9).

Although respondents could indicate several different motivations for installing a heat pump, responses were most frequently associated with space cooling needs and saving money on energy bills. Most respondents (n=5) installed a heat pump to add cooling where there was not previously a whole-home space cooling system. Four respondents each wanted to reduce energy bills in winter months and wanted to add space heating or cooling for a new or renovated space. Three respondents wanted to reduce their reliance on natural gas or delivered fuels (Figure 4).

Figure 4. Motivations for Installing a Heat Pump



Source: Heat Pump Market Rate Customer Survey Question B7. "What were the main reason(s) you decided to install a heat pump in your home?" (n=9; multiple responses accepted)

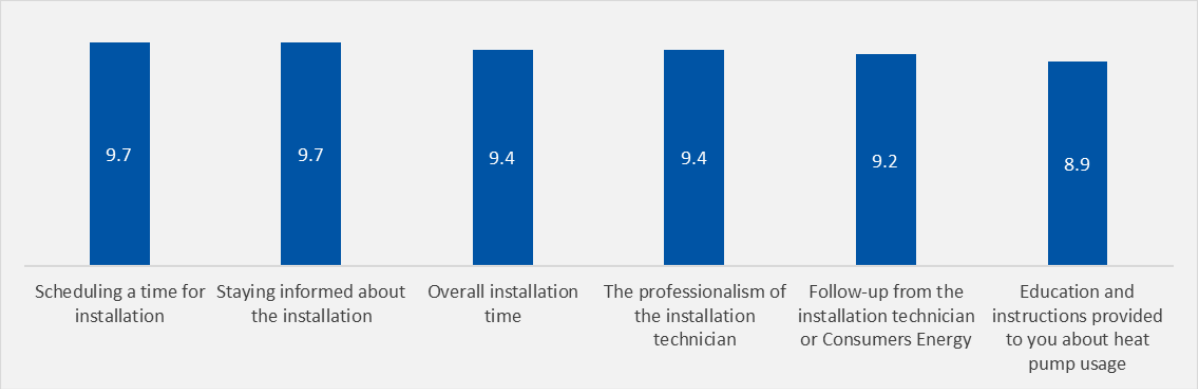
When asked to rate the importance of several factors in their decision to install a heat pump, respondents rated energy savings (over the previous heating/cooling system) as the most important (with a mean rating of 9.1 on a 10-point scale, where 1 meant *not at all important* and 10 meant *extremely important*). The contractor's recommendation received a mean rating of 8.0, and the rebate amount received the lowest rating of all decision factors, at 7.6.

Installation Experience

Respondents were engaged with the installation experience: all of them were present during the installation. Most (eight of nine) received instructions on how to set up and control the heating and cooling schedule on their heat pump at the time of installation. Only one respondent said the installation contractor set up a heating and cooling schedule for them but said they had adjusted that original schedule to address changes in their home's conditioning needs.

Respondents provided very high ratings for aspects of the installation experience, with scheduling and staying informed about the installation receiving the highest mean ratings (of 9.7 on a 10-point scale, where 1 meant *unacceptable* and 10 meant *outstanding*; see Figure 5).

Figure 5. Installation Experience Ratings



Source: Heat Pump Market Rate Customer Survey Question D2. "How would you rate each of the following installation experiences with the heat pump offering?" (n=9)

The lowest rating (of 5) was provided by one respondent for the "education and instructions provided about heat pump usage," but that person did not answer the follow-up question about why they gave that rating.

Heat Pump Perceptions

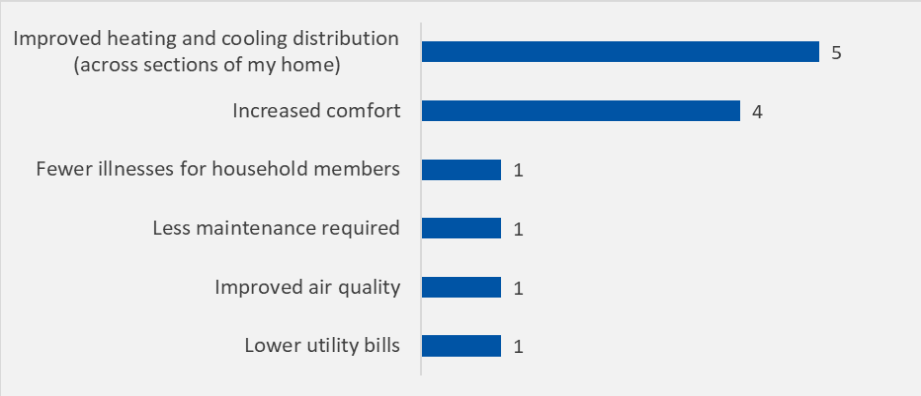
Most respondents (seven of nine) said their home is more comfortable after installing the heat pump, while the other two respondents said their home is equally as comfortable as before the heat pump was installed. One respondent also volunteered that their home air quality was vastly improved, which was also a primary reason they installed the heat pump.

Five respondents rated the comfort level provided by the heat pump in winter months, providing a mean rating of 8.6 on a 10-point scale, where 1 meant *unacceptable* and 10 meant *outstanding*. None indicated any concerns with the heat pump's ability to heat to a preferred comfort level. Comfort ratings for summer months were higher, at an average of 9.1 with ratings from all nine respondents.

Overall, perceptions were mixed about whether respondents had seen savings on their energy bill since the heat pump was installed. Four respondents said it was too soon to tell if their energy bill was affected, while two said they had a lower-than-expected energy bill and two said they had not seen a lower-than-expected energy bill.

In addition to energy savings, respondents reported several additional benefits that they value in their heat pump. With several response options provided, the most frequent benefit selected (by five respondents) was improved heating and cooling distribution across sections of the home (Figure 6). This was followed by four respondents who said the heat pump provided increased comfort. One respondent each indicated having lower utility bills, less required maintenance, improved air quality, and fewer illnesses for household members.

Figure 6. Heat Pump Benefits

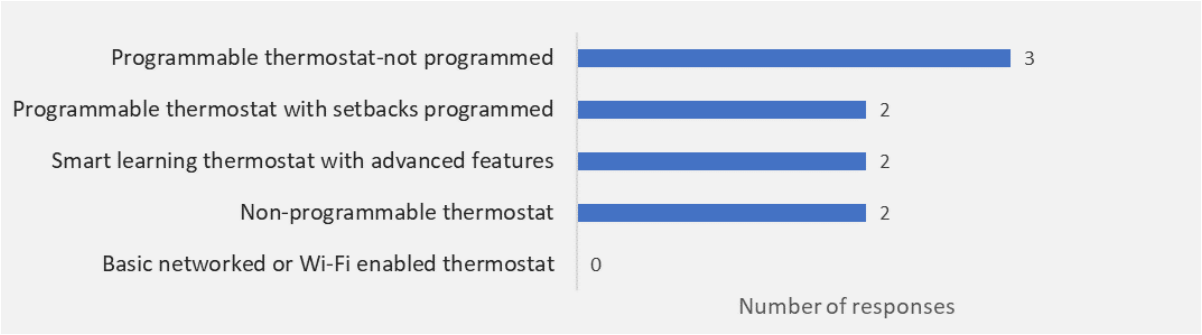


Source: Heat Pump Market Rate Customer Survey Question D13. "In addition to energy savings, if any, are there any other benefits you have experienced or observed from the installation of a heat pump?" (n=9; multiple responses accepted)

Thermostat Usage Behavior and Experience

While five of nine respondents had programmable thermostats, only two of those five used programmed temperature setbacks to control their heat pump temperature settings. Two respondents had smart learning thermostats with occupancy sensing and schedule learning capabilities, and two others had non-programmable thermostats with manual-only controls (Figure 7).

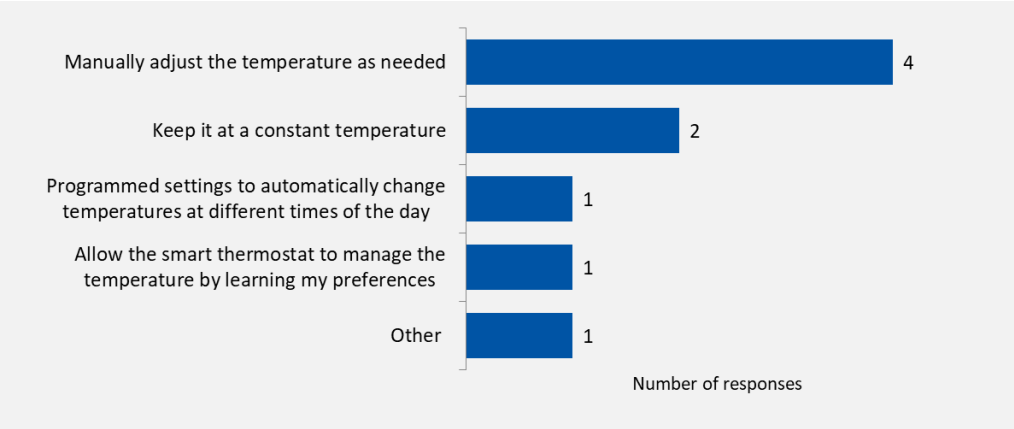
Figure 7. Respondent Thermostat Types



Source: Heat Pump Market Rate Customer Survey Question C1. "What type of thermostat do you have in your home?" (n=9)

Respondents, either singularly or with other household members, monitor and adjust the home heating and cooling settings. Despite most having programming capability through their thermostats, four of nine said they adjust the temperature manually (Figure 8).

Figure 8. Thermostat Management



Source: Heat Pump Market Rate Customer Survey Question C3. "How did your household most frequently manage your thermostat to control the temperature in your home this summer?" (n=9)

Satisfaction with the Offering and with Consumers Energy

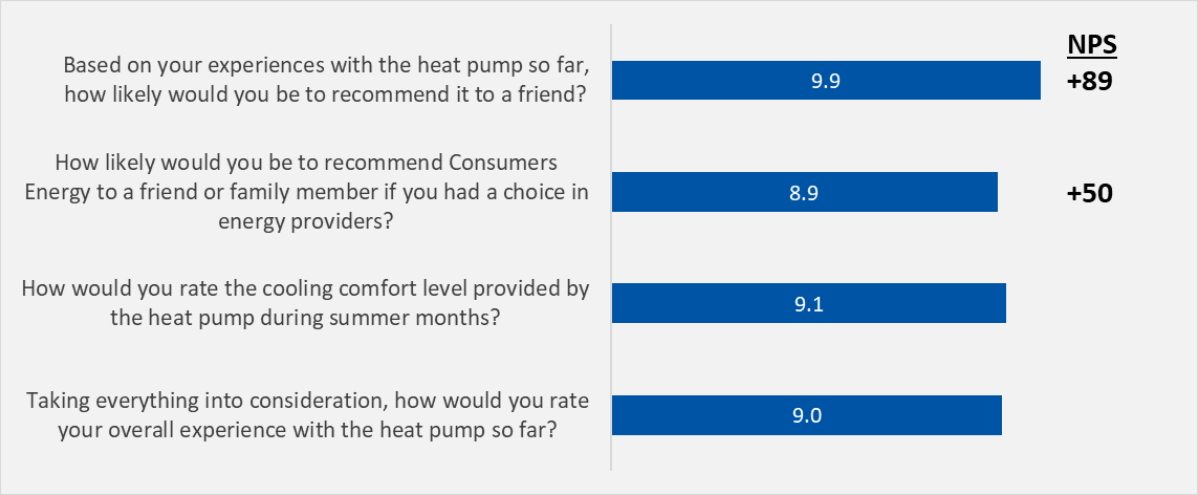
Overall, respondents were highly satisfied with the heat pump (giving a mean rating of 9.0 on a 10-point scale, where 1 meant *unacceptable* and 10 meant *outstanding*), with all nine respondents giving a rating of 8 or higher for their overall experience with the heat pump.

Another key measure of customer satisfaction is the percentage of customers who are highly willing to recommend a product, service, or company after subtracting the percentage of customers who are highly unlikely to recommend that same product, service, or company. The net percentage of those willing to promote the product is the net promoter score (NPS), expressed as an absolute number between -100 and +100 that represents the difference between the percentage of promoters (respondents giving a rating of 9 or 10) and the percentage of detractors (respondents giving a rating of 1 to 6). The Evaluation team calculated a NPS for the two likelihood to recommend questions (likelihood to recommend the initiative and likelihood to recommend Consumers Energy).

Based on their experiences, respondents were highly likely to recommend the heat pump to a friend. As shown in Figure 9, nearly all respondents (eight of nine) gave a rating of 9 or higher (with a mean of 9.9), with three indicating that they had already recommended the heat pump rebate to a friend. The resulting NPS for the heat pump is +89.

Five of eight respondents (63%) provided a rating of 9 or 10 for their likelihood to recommend Consumers Energy to a friend. Only one respondent rated their likelihood to recommend as a 5. The resulting NPS for Consumers Energy is +50, with a mean rating of 8.9.

Figure 9. Market Rate Heat Pump Participant Satisfaction



Source: Heat Pump Market Rate Customer Survey Questions D10, B1, D7, and D9. All questions used a 10-point rating scale, where 1 meant *extremely unlikely* and 10 meant *extremely likely*, with an "already did" response option as a 10 rating (n=9).

The NPS for recommending the heat pump is considered very high and compares favorably to other efficiency programs with similar measures. For example, HVAC participants provided a program NPS of +76 and a Consumers Energy NPS of +63 in 2021. Again, caution is recommended in interpreting numeric results due to the small sample size with the Residential Market Rate pilot response population.

When asked to elaborate on their rating for recommending Consumers Energy, respondents gave positive comments:

- "Consumers Energy has been a good power company. They keep us informed on rebates, power outages, etc. During power outages they are great at restoring power quickly and keeping us informed on time frames. The rebate for heat pumps was one of the reasons we decided to try a heat pump. Our power bill has gone up, but we are using our heat pump a fair amount. It is still a better option than the window air conditioner that we had before."
- "It's been a great company. I grew up in a Consumers [Energy] home and have had one [a heat pump] my entire adult life."
- "High marks for programs and communication."
- "Very happy with service and energy offers."
- "[I] like that Consumers [Energy] is trying to help on heating costs that are going up every year."
- "We don't really have much choice, but I think that Consumers Energy does a good job providing (mostly) reliable electric service (which is all you [they] provide to my area)."

Two respondents said they do not have a choice in energy company, so they do not have a point of comparison, and one commented on high rates.

The only improvement suggestion respondents provided did not directly pertain to the heat pump initiative: "Allow me to change the energy conservation program I want more than once a year. We would like to 'follow the rules' imposed during the summer year-round but cannot change because we cancelled the program we had been on (Consumers [Energy] could limit our AC during peak periods) because our contractor did not want Consumers [Energy] to be able to change our now Wi-Fi–capable system (the old one was not [Wi-Fi]) in May/early June. We did not find out about the option we'd like until later in the summer but were not allowed to use it."

Impact Analysis

The Evaluation team conducted an engineering analysis of the impacts from the Residential Market Rate pilot and relied on MEMD assumptions and information we had collected from customers such as home vintage, presence of central cooling, installed system coefficient of performance (COP)[15] at 5°F, rated heating seasonal performance factor (HSPF) and SEER, tonnage, and other data. The Evaluation team relied on the MEMD weighting tool, which generates a single measure output based on home vintage, climate zone, sizing, and efficiency levels. Since the MEMD weighting tool does not allow for varying the baseline equipment type or system efficiency, the Evaluation team used MEMD building simulation output data to develop site-specific consumption values. MEMD staff provided underlying MEMD 2019 weighting tool building simulation results for ASHPs in single-family buildings.[16] This section summarizes key findings from the engineering analysis.

There were 42 Residential Market Rate pilot CCHPs installed in homes with electric and propane heating, making up the largest percentage of pre-installation heating fuels (Table 6). Approximately half of the CCHPs were installed in homes built before 1979 (n=25) and most of the other half were installed in homes built between 1980 and 2004 (n=23). The remaining CCHPs were installed in homes built between 2005 and present day (n=3).

Table 6. Home Construction Vintage Distribution by Pre-Installation Heating Fuels

Pre-Installation Heating Fuel	1979 or older	1980 to 2004	2005 to Present	Total
Electricity	10	6	0	**16**
Propane	9	15	2	**26**
Fuel Oil	3	1	0	**4**
Natural Gas	3	1	1	**5**
Totals	**25**	**23**	**3**	**51**

[15] Coefficient of performance is simply the ratio of power (kW) in heating (or cooling) Btus generated by the CCHP, and the power (kW) that is supplied to the compressor. The higher the COP, the greater the heating energy generated for each kilowatt consumed by the CCHP.

[16] The MEMD 2021 building simulations for this measure have not been updated since 2019 and therefore reflect the latest building simulation results.

Table 7 shows the average Residential Market Rate pilot participant' annual energy and utility bill savings by pre-installation heating fuel type. Customers heating with delivered fuels (propane and oil) realized the highest heating energy savings, while customers heating with electricity prior to installation of the CCHP had the highest utility bill savings.

Table 7. Average Market Rate Cold-Climate Heat Pump Energy and Fuel Cost Savings per CCHP

Pre-Installation Heating Fuel	Number of Installed Units	Average Savings per CCHP		Average Annual Utility Bill Savings per CCHP
		Heating (MMBtu) [a]	Cooling (kWh) [b]	
Electricity	16	35	-108	$1,680
Propane	26	68	-27	$1,223
Fuel Oil	4	70	-46	$910
Natural Gas	5	54	-228	-$451

[a] Due to the different heating fuel types, savings are represented in MMBtu to allow for better comparisons.

[b] Negative savings mean that electric consumption increased rather than decreased.

The five homes that heated with natural gas will likely see an increase in their utility bill of $451 per year on average due to the relative costs of electricity and natural gas at the time of the analysis, as well as the fact that four of five homes did not have existing central AC (which will likely increase their electric usage in the summer).

As shown below in Table 8, only 22 of the 51 participants had central AC prior to the CCHP installation. For homes without central cooling, the Evaluation team assumed a portion of the homes use room or window AC units to provide some cooling. Due to the low number of homes without conditioned cooling, electric consumption increased, on average, across all baseline heating fuel types. However, homes that did have central cooling before the CCHP installation saw savings from $20 to $96.

Table 8. Central Cooling Presence Distribution and Associated Cooling Savings

Pre-Installation Heating Fuel	Central Cooling?	Number of Installed CCHPs	Annual Cooling Electric Savings per CCHP
Electricity	Yes	5	$33
	No	11	-$37
Propane	Yes	15	$57
	No	11	-$69
Fuel Oil	Yes	1	$96
	No	3	-$35
Natural Gas	Yes	1	$20
	No	4	-$50

Table 9 shows the total Residential Market Rate pilot annual energy and utility bill savings by pre-installation heating fuel type for all CCHPs.

CADMUS

Table 9. Total Market Rate Heat Pump Energy and Fuel Cost Savings

Pre-Installation Heating Fuel	Count of Installed CCHP Units	Savings		Annual Fuel Costs [b]		Pre-Installation Central Cooling Saturation [c]
		Heating (MMBtu) [a]	Cooling (kWh)	Heating	Cooling	
Electricity	16	565	-1,729	$27,124	-$247	31%
Propane	26	1,774	-704	$31,701	$85	58%
Fuel Oil	4	279	-183	$3,652	-$10	25%
Natural Gas	5	270	-1,142	-$2,072	-$182	20%

[a] Due to the different heating fuel types, savings are represented in MMBtu to allow for better comparisons.

[b] The Evaluation team calculated annual heating and cooling costs based on rates and distributed fuel cost shown in *Appendix B*.

[c] Not every home was equipped with central cooling before the CCHP installation.

Income Qualified Multifamily Initiative Findings

There are two key groups of participants in the Income Qualified Multifamily initiative: property owners and managers (PMO) and tenants. PMOs are active participants who sign up for the initiative and are the primary contacts of the initiative. The tenants are indirect participants; they are not decision-makers, yet they directly benefit from the CCHP Initiatives' equipment and energy savings in their living units and they most frequently pay the resulting energy bills from CCHP operation. The Evaluation team sought feedback from both groups, conducting telephone interviews with PMOs and online surveys with tenants. The Evaluation team also sought to understand the Income Qualified Multifamily initiative's performance by analyzing electric energy savings impacts during the heating and cooling seasons through a statistical billing analysis of participating initiative properties.

This chapter outlines the results of PMO interviews, tenant surveys, and the statistical billing analysis.

Property Manager and Owner Interviews

The Evaluation team conducted telephone interviews with multifamily PMOs who participated in the CCHP initiative to gain insight into their experience. The Evaluation team designed the interview to address several key objectives:

- Document the participant installation experience
- Document participant usage behavior and experience
- Document awareness and perceptions of heat pumps
- Document participant decision-making around participating in the heat pump offering
- Identify marketing and outreach best practices
- Assess satisfaction with the offering and with Consumers Energy

As of Q3 2021, seven multifamily properties had participated in the Income Qualified Multifamily initiative. While the Evaluation team attempted to recruit all seven of the multifamily PMO initiative participants, we completed three phone-based in-depth interviews. Two of the multifamily PMO participants were from existing buildings (retrofit installations) and therefore had broad insights into the full initiative experience. The third interviewee was with a newly constructed property, which meant they had a more limited view on the tenant and installation experience.

Installation Experience

Overall, the multifamily PMOs had a positive early-stage initiative experience with scheduling, installation, and follow-up. Two of the three PMOs reported that COVID-19 caused some delays with the installation and equipment, but overall reported positive experiences. In one case, the PMO commented that the completion time was fast considering the number of units and installs: "We had something like 48 units, some large enough for multiple installations…so two-and-a-half months to install over 50 units was fast." The third PMO, the owner of a new construction property, noted the while installations were all completed on time, they did not have feedback on the tenant experience during installation (as installation happened before tenants occupied the units). For the other two PMOs with tenants living in

the units, the installer worked directly with management to notify the tenants of the installations and work around their schedules. According to these two PMOs, their tenants were generally satisfied with the heat pump installation.

Heat Pump Usage Behavior and Experience

The multifamily PMOs reported that prior to installation, tenants relied on inefficient electric baseboard systems and, in one case, had specifically requested new a HVAC system during a tenant meeting. One of the primary benefits for tenants is the ability to use AC as well as heating—while the heat pump replaced baseboard heat, there was no existing AC to replace outside of window units purchased by tenants. One PMO mentioned that nearly all tenants enjoyed the new heat pumps, with only a few tenants being confused about how to use the new system.

Two of the multifamily PMOs received direct feedback from their tenants regarding the heat pump usage and experience. According to one PMO, "the residents considered it a huge plus for them, because of all the extra benefits that the heat pumps provided them." Another PMO remarked that the heat pumps provided significantly greater comfort, and improved air circulation, compared to the baseboard equipment, and went on to state, "the heating itself is just more efficient for the tenants; it seems to keep the apartments warmer."

Awareness and Perceptions of Heat Pumps

Multifamily PMOs were generally aware of heat pumps prior to being approached by Consumers Energy about the rebate initiative, though they were not aware of Consumers Energy incentives or programs until their involvement in the initiative. One PMO previously had contractors recommend heat pumps, while another had heat pumps installed in other apartments in the Southeast United States (where heat pumps are more common). One of the PMOs had some hesitation about installing the CCHPs, as they noted, "historically, my understanding was that [heat pumps] didn't do so well in cold climates. A green consultant and several HVAC engineers turned me on to them and then [I] became comfortable [that] they would be sufficient."

PMOs generally did not report any perceived benefits of heat pumps prior to installation but were happy to report both energy and non-energy benefits, particularly tenant happiness and reduced maintenance and tenant comfort needs, after installation. As an added benefit, the simplicity of a single heating and cooling system was beneficial for both tenants and the PMOs: the number one benefit is providing heat, but efficient heat is the next important thing. As one PMO said, "There is always some kind of system [to heat], but it doesn't always work. It's always our number one concern to provide heating and cooling to the tenants."

Decision-Making around Participating in the Heat Pump Offering

In both existing retrofit cases, the PMOs primarily decided to improve the existing HVAC systems due to energy efficiency and tenant comfort. One PMO cited a tenant meeting as a primary factor, where tenants explicitly requested an improved HVAC system. Generally, all PMOs wanted to improve tenant comfort, replace old equipment, improve electric efficiency, and lower electricity bills. The biggest barrier to switching over to heat pumps was cost: because the multifamily buildings already had existing

heating systems, it was a matter of prioritizing which are the most in need and how to fit that into the budget: "… if there is an existing heating system that is working, that's not necessarily something we can improve because it meets [the need for] having a functioning system, and it's harder and more expensive to switch out than other properties… so the biggest barrier is a matter of prioritizing it [CCHP installation] in the budget." According to the other retrofit PMO, the rebate allowed them to fit improved HVAC systems into the budget for that year. Tenant comfort, energy efficiency, and an improved system were the key motivations for PMOs.

For the new construction PMO, heat pumps were an attractive investment for their property, and the initiative made it "a slam dunk" for the project. The initiative allowed the property to meet LEED certification while also managing to keep the construction within budget. As the new construction PMO noted, "for our LEED-certified property, which was an all-electric building, and given [that] the units were smaller apartments, it was hard to find a furnace that would work well and integrate into the units and not be oversized. The heat pumps can really work well and are adapted to lower need, relative to [a] gas furnace. The simplicity of only electric, with no gas, requiring less piping, meant that construction was easier." This PMO went on to remark, "with the rebate, the heat pump was actually the cheaper option [relative to a gas furnace]."

Marketing and Outreach Best Practices

Multifamily PMOs agreed that the best way to conduct outreach about CCHPs is to directly contact contractors or developers. According to two PMOs, they primarily get their recommendations from contractors, who do not always provide information on CCHPs and higher-efficiency opportunities to the developers. One existing building PMO said, "if I had someone directly to talk to, I would bring this up to [building owners] more…I confer with architects and specialists on building recommendations, but they don't necessarily know all the tenant benefits. So, I would recommend reaching out to more developers, like myself, directly." Both PMOs recommended emails or pamphlets with the overall costs and energy savings and direct information as a convincing outreach strategy: "Anything that involves a description, some costs, energy savings…I think those are the highlights," the construction manager said.

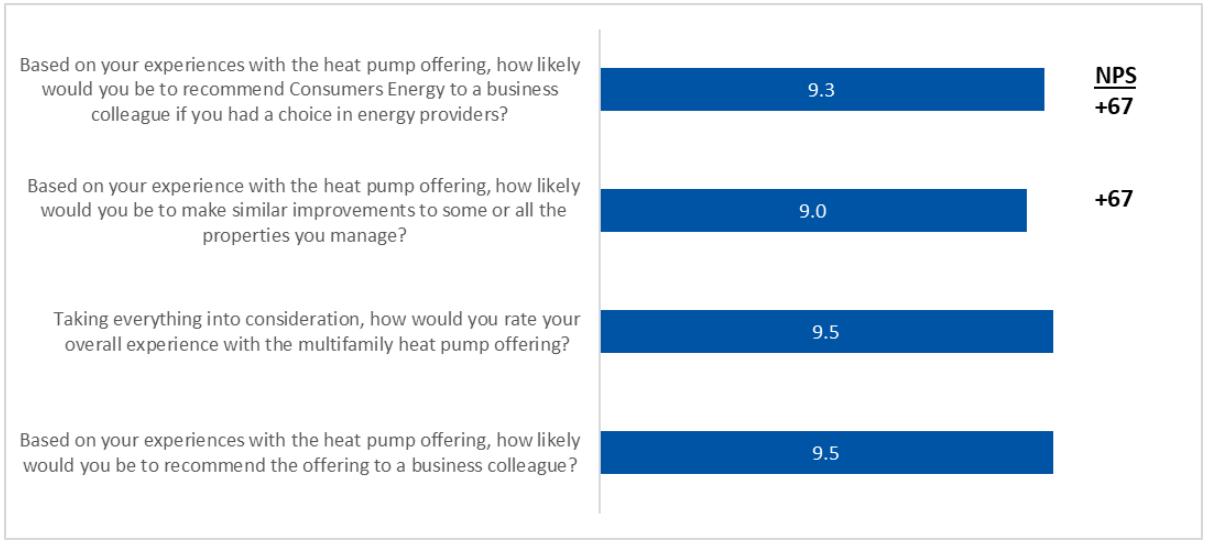
Two of the PMOs learned about the heat pump offering through direct contact with Consumers Energy, while one learned about it from their LEED consultant. When asked what the preferred means of communicating future offerings, all three PMOs tended to prefer email, but also noted phone calls.

One interviewee (the resident manager) mentioned that his property manager was the decision-maker in the process, and that energy companies should do more to contact property managers directly, because most are not aware. "[The property manager] was different," the resident manager said, "He was always searching for rebates and things like that…both to improve the apartments for the tenants, but also because of the resource—using less energy is good for the economy, that kind of thing. But most property managers aren't searching like he was." Another PMO said, "Most people don't know enough and aren't aware [that heat pumps] can work on their own in colder climates. We have now had a full winter with new tenants and the CCHPs and received no complaints: it all went well."

Satisfaction with the Offering and with Consumers Energy

Overall, the participating PMOs were highly satisfied with their initiative experience and with Consumers Energy (Figure 10). The three PMOs provided an average rating of 9.5 on a 10-point scale (where 1 meant *unacceptable* or *extremely unlikely* and 10 meant *outstanding* or *extremely likely*) for their satisfaction with the initiative and their likelihood to recommend heat pumps to a colleague. The PMOs also rated their likelihood to recommend Consumers Energy as a 9.3 and rated their likelihood to adopt similar CCHP equipment in their other properties as a 9.0 (Figure 10).

Figure 10. Multifamily Property Manager Owner Cold-Climate Heat Pump Satisfaction



Source: Heat Pump Property Owner and Manager Interview Guide Questions G1–G4.

Income Qualified Multifamily Tenant Survey

In November 2021, the Evaluation team surveyed a group of multifamily tenants who resided in units that received CCHPs as part of Consumers Energy's CCHP initiatives and 32 completed the survey

The Evaluation team designed the survey to address several key objectives:

- Document awareness of heat pumps
- Understand the participant installation experience
- Assess tenant perceptions of heat pump impacts on comfort levels and electricity bills
- Document participant usage behavior and experience
- Assess satisfaction with the offering and with Consumers Energy

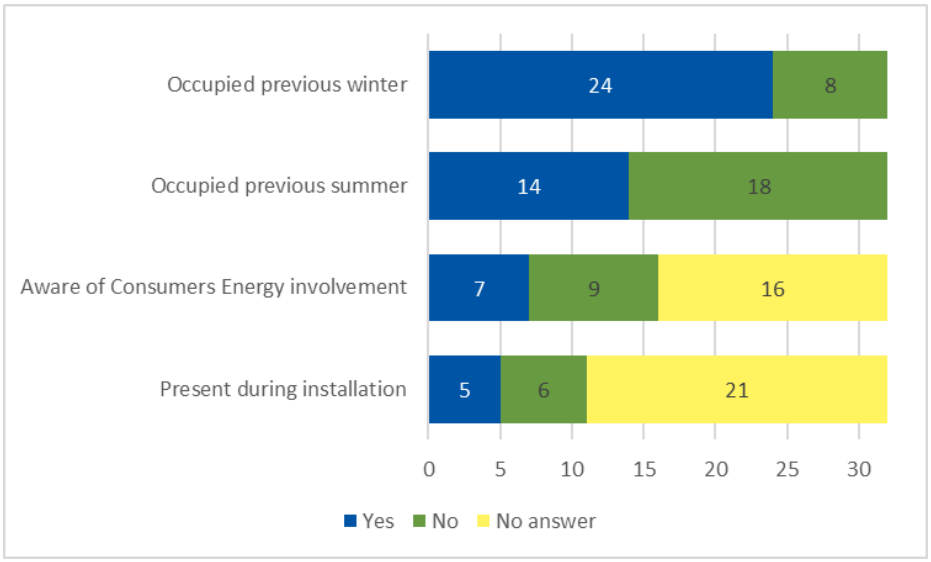
Tenant Survey Background

The multifamily tenant survey included questions about topics such as whether respondents manage the temperature of their unit, whether they pay their bills, and how long they have resided in their unit. Additionally, the team asked questions about the installation and performance of the CCHP.

All tenants who responded to the CCHP survey managed the temperature of their home personally and all said they pay their own energy bills (n=32). Most tenants (n=17) had lived in the apartment for between six months and one year while 11 others had occupied their apartment for more than one year. Additionally, three respondents said the heat pumps had not yet been completely installed and they could not provide answers about installation or post-installation.

Other participant characteristics are summarized in Figure 11. A minority of respondents were present during installation (n=5) and were aware of Consumers Energy involvement in the CCHP (n=7). Three-quarters of respondents were occupants last winter (n=24), before the installation, while one-quarter (n=8) were not present in their units to experience the old heating system, and thus could not provide comparative responses about new versus old heating system performance. Respondents' tenancy term and other factors resulted in around one-third (30%) of the responses to all questions that provided little to no insight into their experience in this initiative. Because of the low response count to many of the tenant survey questions, the results should be considered indicative but inconclusive.

Figure 11. Summary Respondent Characteristics



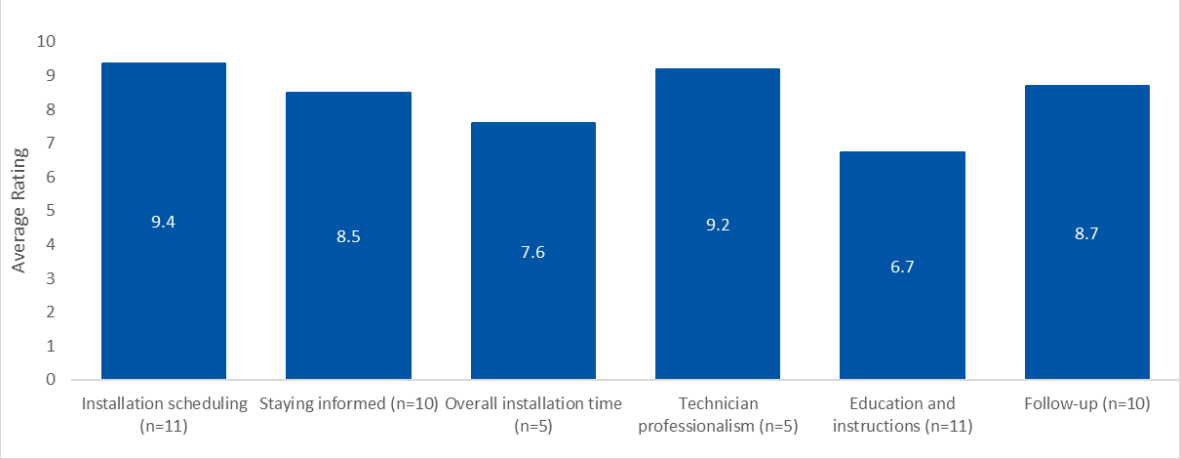
Source: Heat Pump Multifamily Tenant Survey Guide Questions C5, C8, B3, and C1. Please see *Appendix E* for specific question wording.

Participant Installation Experience

A successful equipment installation can provide tenants with a positive initiative experience; such an installation should include providing helpful information and operational details for a better managed heating and cooling experience. One-third of respondents (n=11) provided installation experience ratings. Overall, participants were largely satisfied with the installation experience, rating most installation elements above an 8 on a 10-point scale, where 1 meant *unacceptable* and 10 meant *outstanding* (Figure 12). Respondents provided the lowest average rating to the education and instructional aspects of installation, which impacted their overall satisfaction with the heat pump

offering, as well as with Consumers Energy overall (these metrics are featured further below in Figure 19).

Figure 12. Tenant Installation Satisfaction

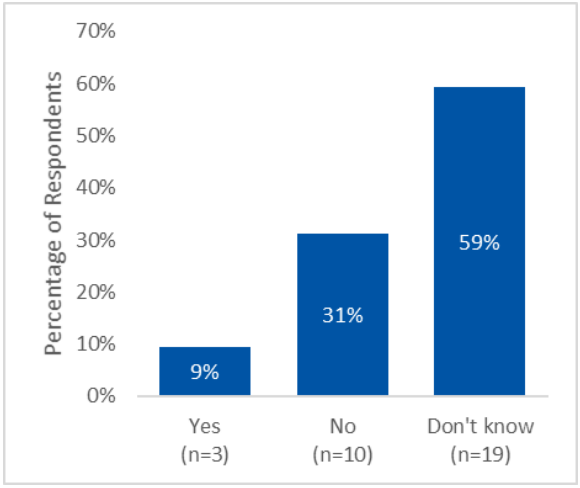


Source: Heat Pump Multifamily Tenant Survey Guide Question C2. "How would you rate each of the following installation experiences with the heat pump offering?"

Participant Usage, Behavior, and Experience

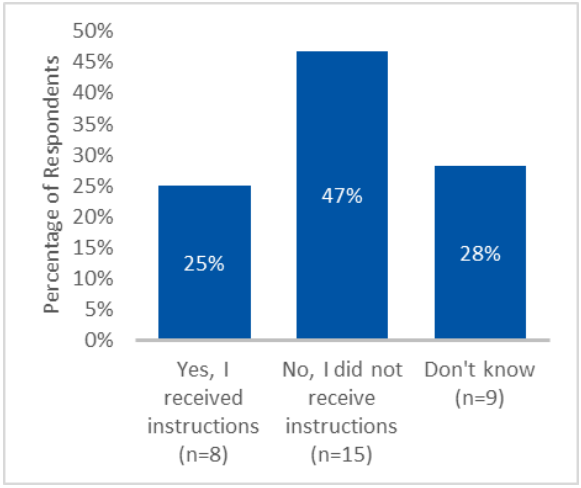
Participant usage, behavior, and experience with this offering were influenced by the installation technicians and education surrounding the CCHP equipment installation. Only three respondents could confirm with certainty that the technician set up a heating and cooling schedule for their heat pump (Figure 13). These three participants also confirmed that the heating and cooling schedule set up by the contractor is still in operation. Lack of heat pump education, materials, and follow up were common among respondents. Forty-seven percent of participants (n=15) reported not receiving documentation or instructions about the heat pumps, while 28% (n=9) did not know if they received instructions and 25% (n=8) did receive instructions (Figure 14). Other survey respondents indicated in open-ended responses that there was a lack of information relayed about the heat pumps, either from installation technicians, the PMOs, Consumers Energy, or a combination of the three.

Figure 13. Heating and Cooling Schedules



Source: Heat Pump Multifamily Tenant Survey Guide Question C16. "Did the installation technician set up your heat pump on a heating and cooling schedule?"

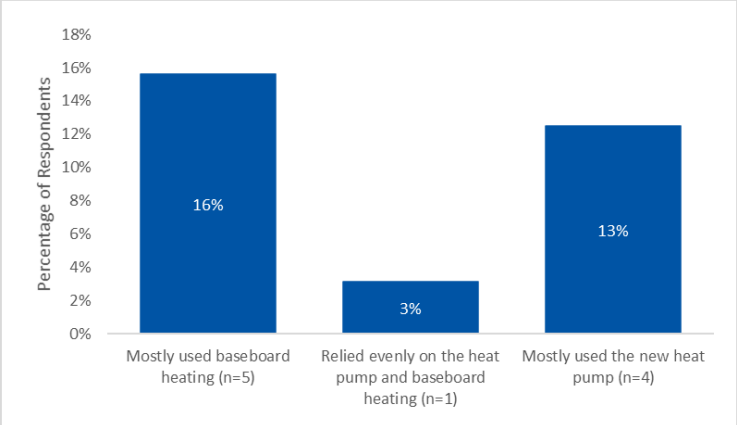
Figure 14. Instructions Provided at Installation



Source: Heat Pump Multifamily Tenant Survey Guide Question C18. "Have you been provided with instructions on how to set up and control your heating and cooling schedule on your heat pump?"

Sixteen percent (n=5) of participants reported using mostly baseboard heating after installation, while 13% (n=4) reported using mostly the newly installed heat pump and 3% (n=1) reported using both evenly. Another 68% (n=22) of participants did not know which heating source they relied on.

Figure 15. Primary Multifamily Tenant Apartment Heating Source



Source: Heat Pump Multifamily Tenant Survey Guide Question C12. "Which of the following best describes how you heated your apartment last winter?"

In open-ended responses, some tenants were unhappy with the lack of information:

- "After the installation, there was not follow up. Also, there are many in our complex that have no idea on how to set up the mobile app."
- "Manager of my complex did not [educate] me on how to use all the features. Also, when and who changes the filters, if any."

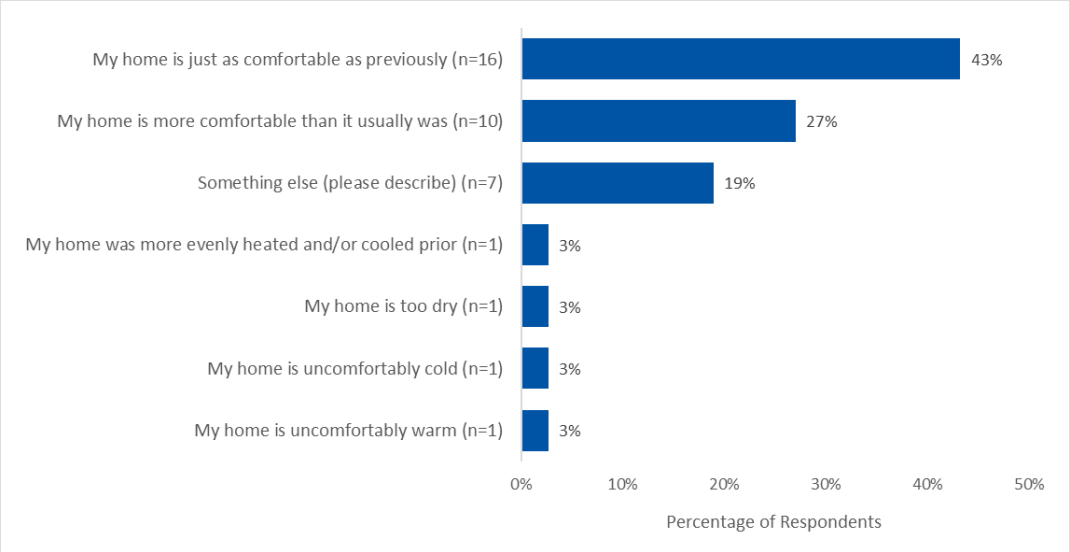
Awareness and Perceptions of Heat Pumps

Most participants (68%; n=21) reported a complete lack of knowledge regarding heat pumps, even after installation. More interestingly, half were not aware that there was a heat pump installed in their apartment, despite having occupied the unit at the time of installation. Of the half that were aware of the heat pump installation, 56% (n=9) did not know Consumers Energy was involved in the project. In an open-ended response, one participant was surprised: "I didn't know anything about how to run the heat pump or maintenance needed. We weren't told anything. We didn't even know Consumers [Energy] funded it."

Perceptions of Heat Pump Impact on Comfort Levels and Electricity Bills

As noted above, PMOs indicated tenant comfort was a key factor in the decision to participate in the heat pump initiative—some tenants supported this perception. Post-installation, although 43% of tenants reported their homes to be as comfortable as before, one-quarter of tenant survey respondents reported increased comfort (27%). Specifically, few tenants reported issues with temperature or humidity regulation, as shown in Figure 16.

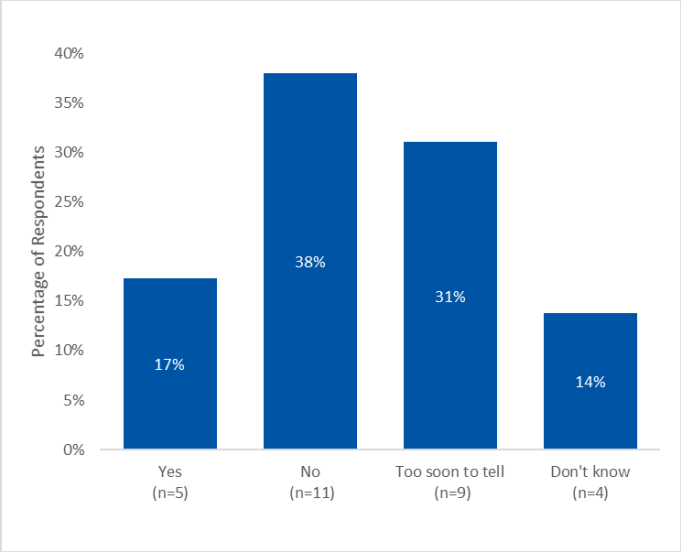
Figure 16. Heat Pumps and Home Comfort



Source: Heat Pump Multifamily Tenant Survey Guide Question C11. "In general, how did the heat pump affect your home comfort?"

Over twice as many income-qualified multifmaily respondents believed they did not experience any savings on their energy bills as those who believed they did experience savings: 38% of respondents (n=11) reported no savings on their energy bills, compared to 17% (n=5) who reported savings (Figure 17).

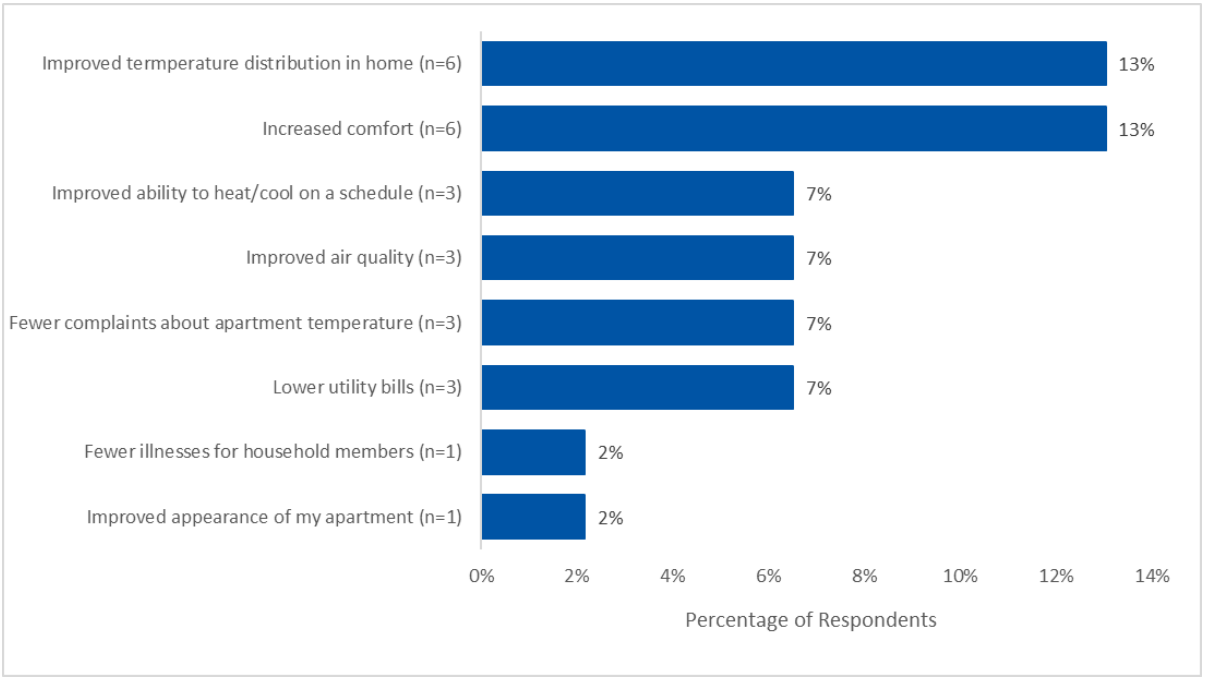
Figure 17. Multifamily Tenant Energy Bill Savings



Source: Heat Pump Multifamily Tenant Survey Guide Question D2. "Have you seen a lower-than-expected energy bill?"

Even with few respondents believing the CCHPs resulted in bill savings, a high number reported non-energy saving benefits of the CCHPs, primarily related to temperature distribution and comfort (Figure 18).

Figure 18. Non-Energy Benefits



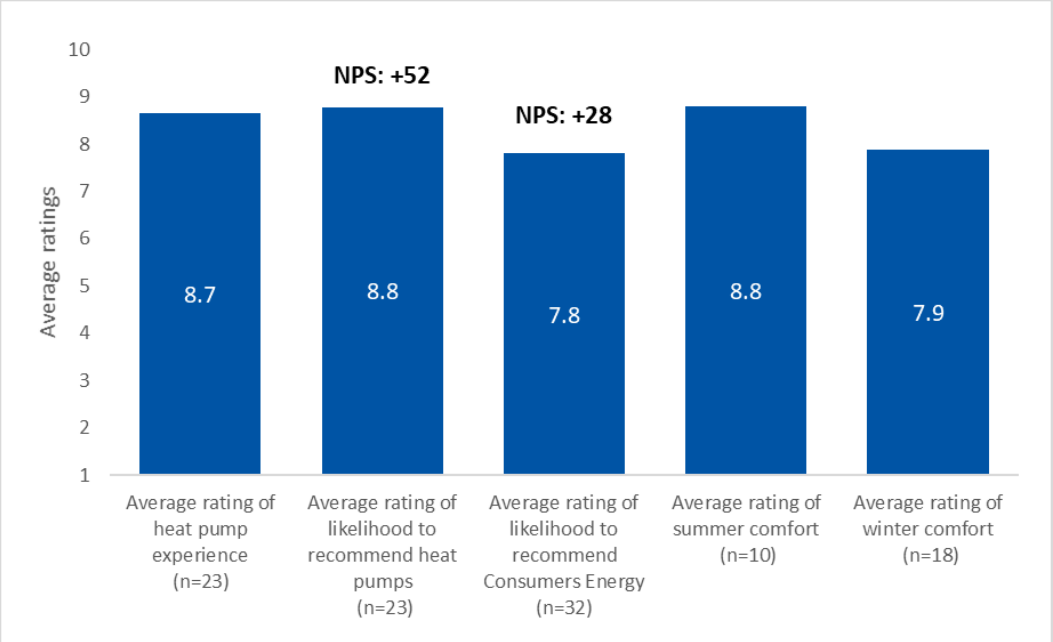
Source: Heat Pump Multifamily Tenant Survey Guide Question D3. "In addition to energy savings, if any, are there other benefits that you have experienced or observed from the installation of heat pumps?"

Satisfaction with the Offering and with Consumers Energy

Income-qualified multifamily tenants were satisfied with the CCHP experience, and generally felt that the heat pumps provided improved winter heating and summer cooling comfort. CCHP multifamily tenant participants reported an average rating of 8.7 regarding their overall experience with the heat pump, an average of 8.8 rating on likelihood to recommend a heat pump to a friend, and an average of 7.8 rating on likelihood to recommend Consumers Energy, all on a 10-point scale where 1 meant *unacceptable* or *extremely unlikely* and 10 meant *outstanding* or *extremely likely* (Figure 19). Respondents also reported an average rating of 8.8 regarding summer comfort and 7.9 regarding winter comfort.

Another key measure of customer satisfaction is the percentage of customers who are highly likely to recommend a product, service, or company after subtracting the percentage of customers who are highly unlikely to recommend that same product, service, or company. The net percentage of those willing to promote the product is the net promoter score (NPS), expressed as an absolute number between -100 and +100 that represents the difference between the percentage of promoters (respondents giving a rating of 9 or 10) and the percentage of detractors (respondents giving a rating of 1 to 6). The Cadmus team calculated a NPS for the two likelihood to recommend questions (likelihood to recommend the CCHPs and likelihood to recommend Consumers Energy – see Figure 19 below).

Figure 19. Satisfaction with Cold-Climate Heat Pump Experience and Comfort



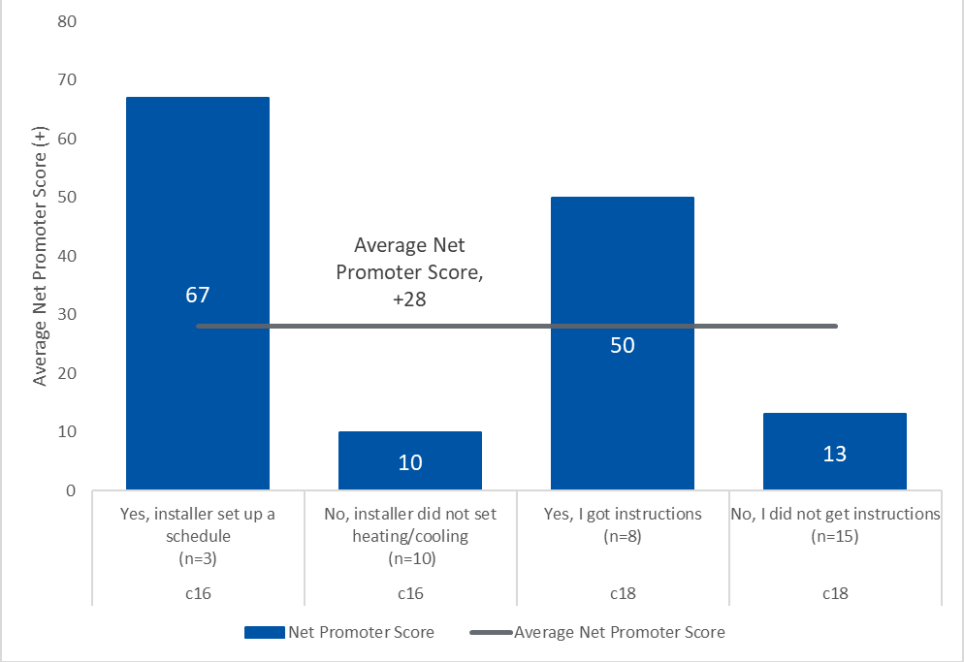
Source: Heat Pump Multifamily Tenant Survey Guide Questions E1, E2, A1, C9, and C6. Please see *Appendix E* for specific question wording.
This figure reflects combined average satisfaction ratings of heat pump experience and comfort.

The Evaluation team also calculated a NPS for the two likelihood to recommend questions (likelihood to recommend the CCHPs and likelihood to recommend Consumers Energy). As shown in Figure 19, based

on experiences with the heat pump, respondents were somewhat likely to recommend the heat pump to a friend. Though 14 respondents were promoters (providing ratings of 10) and only two were detractors, nine respondents did not provide a rating and seven were passives. The resulting NPS for the heat pump was +52. Sixteen respondents provided a 9 or 10 rating for likelihood to recommend Consumers Energy to a friend while seven provided ratings below a 7 and were classified as detractors (nine respondents were classified as passives). The resulting NPS for Consumers Energy was +28.

The Evaluation team compared the Consumers Energy NPS across different participant groups (Figure 20). Participants who provided low ratings on installation communication and instructions and provided verbatim feedback around lack of education materials and instructions were more likely to provide a lower overall Consumers Energy NPS. In fact, this cohort on average provided the lowest ratings of all participants. Additionally, participants who received instructions or had their heating and cooling schedule set by installation technicians had a higher NPS on average than both the survey average and the average of those who had no instructions or schedule set.

Figure 20. Average Consumers Energy Net Promoter Score and Installation Satisfaction



Source: Heat Pump Tenant Survey Guide Questions A1, C16, and C18. “How likely would you be to recommend Consumers Energy to a friend or family member if you had a choice in energy providers?” “Did the installation technician set up your heat pump on a heating and cooling schedule?” and “Have you been provided with instructions on how to setup and control your heating and cooling schedule on your heat pump?”

Open-ended responses regarding Consumers Energy were primarily positive in nature, though some were frustrated with Consumers Energy's service, mostly reporting high bills:

- "Great customer service and payment plans. But the cost in the winter is way higher than I think it should be."
- "My bill was all over the place last winter reaching almost $300 between two small school-aged kids who were gone most of the day and myself who unplugs everything."
- "Because I'm low income with social security income where there's no assistance help for my electric bill, the bill can be extremely expensive."

Nearly all positive responses cited great customer service and the ease of payment:

- "Service has been great for me in as long as I've been with them."
- "Good service and consistent customer service."
- "Very easy online payments and very easy outage center updates. It's also nice to have those text and email reminders about billing."

Impact Analysis

This section summarizes findings from the Evaluation team's statistical billing analysis, conducted to determine electric energy savings resulting from the Income Qualified Multifamily initiative. While the focus of the initiative and the billing analysis were on electric-heated properties (and therefore on electric impacts on heating use during the winter heating season), the Evaluation team also used the billing analysis to determine the electric energy impacts associated with summer cooling season. *Appendix B* has a detailed discussion of the methodological approach we used to determine the energy savings.

Key Findings

The Evaluation team estimated the electric energy impacts of CCHP installations separately for winter electric heating and summer cooling impacts. The Income Qualified Multifamily initiative participant electric savings results, presented in Table 10, show winter electric heating energy savings of 832 kWh, equivalent to 22.9% of baseline weather-sensitive electric heating use.

Table 10. Multifamily Income Qualified Heat Pump Electric Energy Savings

Group	Weather-Sensitive Electric Usage (kWh)		Weather-Sensitive Electric Savings		Precision at 90%
	Pre-Period	Post-Period	kWh	Percentage	
Winter heating	3,626	2,794	832	22.9%	±9%
Summer cooling	234	170	64	27.1%	±24%
Total Annual (Weather Sensitive)	3,860	2,964	896	23.2%	±8%

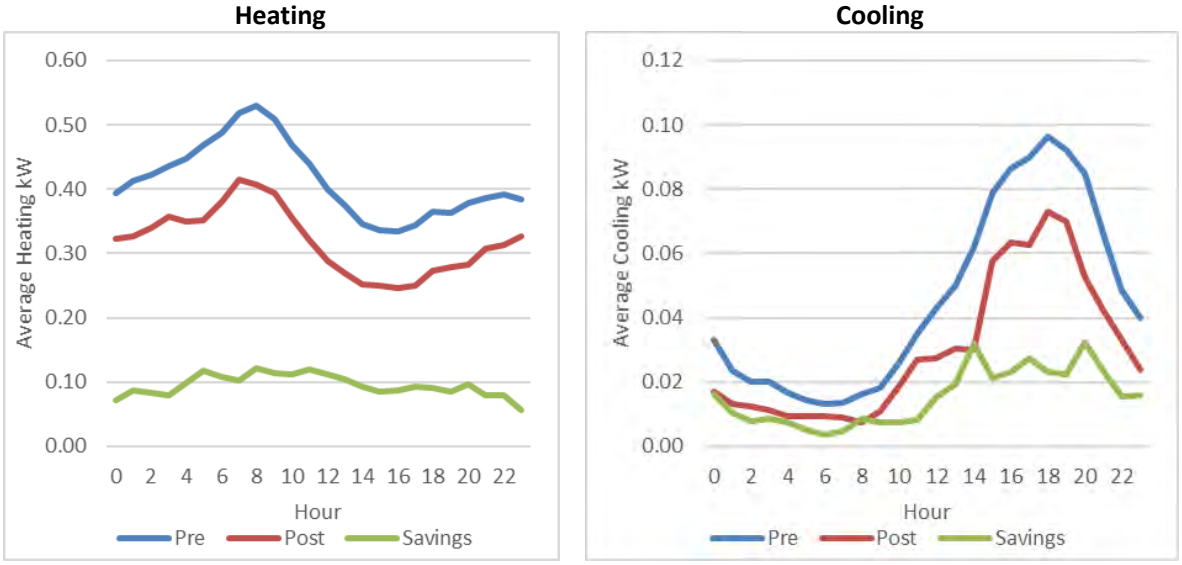
Source: Evaluation team billing analysis.

The billing analysis estimate of 64 kWh savings per unit during the summer cooling season reflected a similar percentage reduction in weather-sensitive electric usage attributable to the CCHPs (at 27%

relative to the 23% for winter heating). The heating electric analysis produced savings estimates within the ±10% precision threshold at a 90% confidence interval and therefore the results were statistically significant. Given the lower cooling load and therefore more variable signal, the cooling savings were outside the ±10% precision target. Overall, the Income Qualified Multifamily initiative resulted in a statistically significant annual reduction of 896 kWh for each participant tenant unit, representing 23.2% of the annual weather-sensitive electric energy use and translating into approximately $147 in annual bill savings for each CCHP participant.

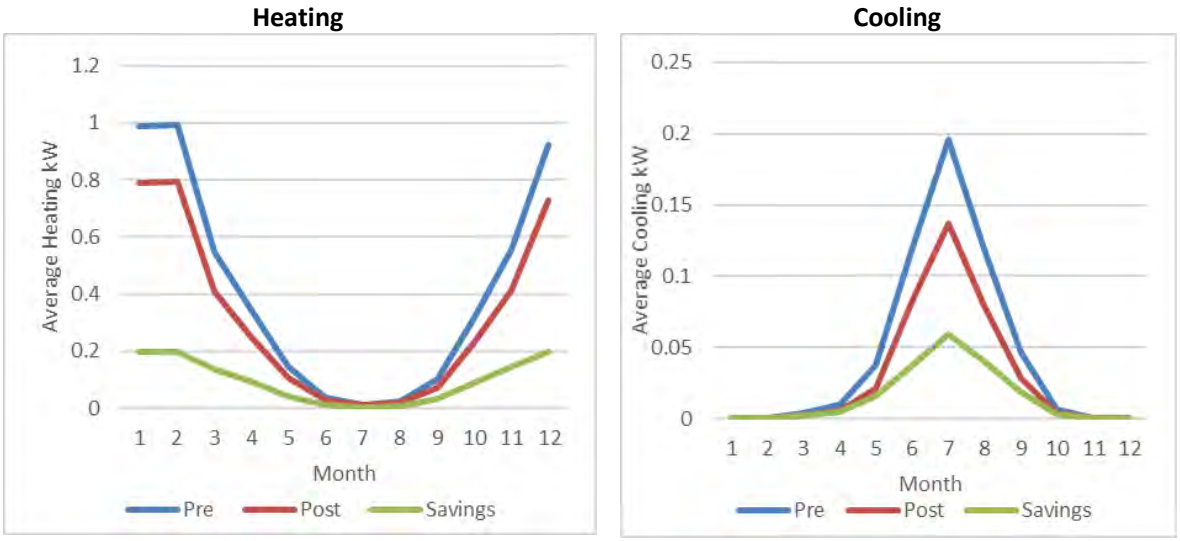
An examination of the heating and cooling load shapes and accompanying savings profile offers insight into how the CCHP impacted heating and cooling usage. Figure 21 shows the average winter and summer daily load shape and resulting CCHP savings profiles. In the winter, participants' CCHP electric energy savings were relatively consistent throughout the day. In the summer, the CCHP cooling savings were coincident with the cooling load periods of mid-to-late afternoons.

Figure 21. Participant Hourly Heating and Cooling Load and Resulting Savings



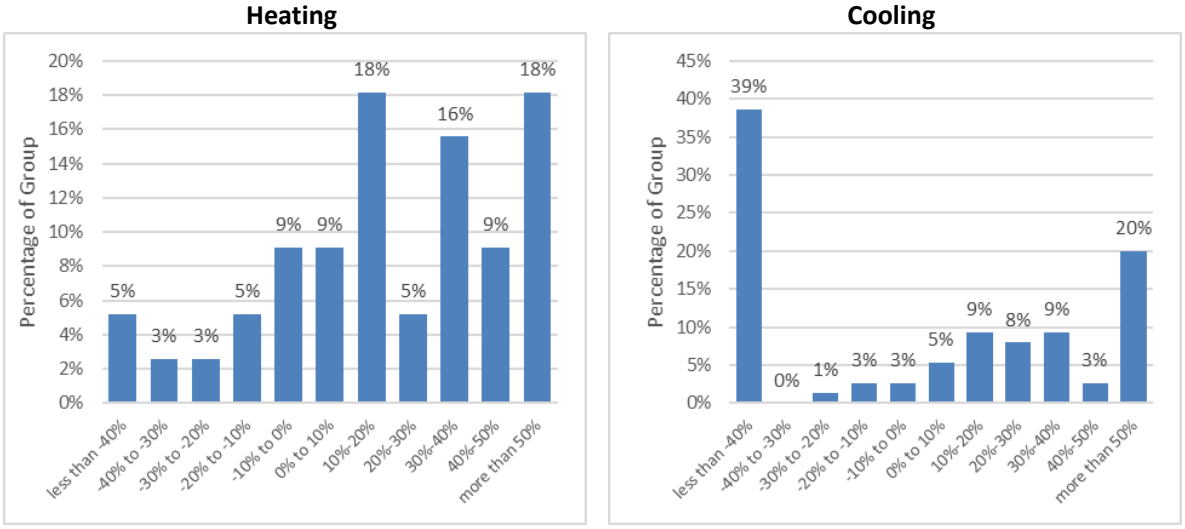
An examination of the average *monthly* load and savings profiles also showed that the savings were consistent with the monthly load shapes (Figure 22).

Figure 22. Monthly Heating and Cooling Load and Resulting Savings



The Evaluation team also explored the variability of savings across the tenant units by grouping the percentage of tenant units according to decile savings bins (incremental steps of 10% savings; see Figure 23). More than 40% of the Income Qualified Multifamily tenants saved over 30% of their pre-installation electric energy during the winter heating season, while the largest group of customers (18%) saved over 50%. On the summer cooling analysis, close to 40% of Income Qualified Multifamily customers had a net increase in summer electric use. These customers likely lacked any pre-installation cooling equipment (no room ACs) or were unlikely to have used their equipment. The second largest group of customers were also the highest saving group, with 20% of the tenants saving over 50% of their pre-installation summer cooling electricity usage.

Figure 23. Percentage Distribution of Annual Heating and Cooling Savings by Savings Bin



CADMUS

Benchmarking of Results

The Evaluation team compiled results from three recent multifamily heat pump retrofit program evaluations in other regions to understand how the results compared to the Consumers Energy Income Qualified Multifamily initiative. A majority of the evaluations were focused on income-qualified properties. As shown by the summary benchmark data in Table 11, the Income Qualified Multifamily initiative findings are consistent with other multifamily income-qualified billing analysis results.

Table 11. Benchmarking of Multifamily Heat Pump Billing Analysis Results

Utility and Program	Percentage Savings	Home Type	Income	Analysis Type
Consumers Energy Income Qualified Multifamily initiative	**23.2%**	**Multifamily**	**IQ**	**Billing Analysis**
2020 Commonwealth Edison Multifamily Income-Qualified Heat Pump pilot (full report not yet public but summary report is here)	25%	Multifamily	IQ	Billing Analysis
2016 Efficiency Maine Low-Income Multifamily Weatherization program (report)	22.2%	Multifamily	IQ	Billing Analysis
2014 Connecticut Energy Efficiency Fund Home Energy Services (Income Eligible) (report available online)	11% [a]	Multifamily	IQ	Billing Analysis
2014 Energy Trust of Oregon Multifamily Ductless Retrofits (report available online)	15% [a]	Multifamily	Any	Billing Analysis
Puget Sound Energy Heat Pump Dealer Channel (not public)	18% [a]	Single Family	Any	Billing Analysis

[a] This represents the percentage of annual load, not the percentage of weather-sensitive load (which was not reported).

CADMUS

Commercial and Industrial Cold-Climate Heat Pump Pilot Findings

Consumers Energy developed its Commercial and Industrial Cold Climate Heat Pump Pilot initiative in 2020 in response to the 2020 Consumers Energy Settlement Agreement with the Michigan Public Service Commission and other stakeholders. Beginning in early 2021, Consumers Energy launched the initiative targeting small commercial and industrial customers, defined as customers with facilities under 20,000 square feet. Initiative staff reached out to customers who did not have access to natural gas or were suspected to have propane heat. Staff then helped these customers choose a contractor to install a CCHP, addressed any questions the participants had throughout the installation process, and provided significant financial support to install new CCHPs; all but one customer had the entire cost fully covered.

For this research, the Evaluation team conducted in-depth telephone interviews with initiative participants to address several key research objectives:

- Explore key factors in customer decision-making regarding CCHP installations
- Explore customer experiences during the CCHP installation process
- Explore customer experiences using their CCHP
- Explore customer experiences with the initiative offering
- Identify opportunities to best support CCHP technology moving forward

In the fall of 2021, the Evaluation team conducted in-depth interviews with seven of the nine initiative participants, asking about heat pump technology awareness and motivations for participation, as well as participant experiences and satisfaction throughout the initiative process and with their new heat pump technology. During the winter of 2021/2022, the Evaluation team also metered the equipment to assess energy savings. Findings from this research are found in the 2021 Cold Climate Heat Pump Pilot Impact Evaluation Memo submitted as part of Consumers Energy's 2021 reconciliation. Metering for the 2022 cooling season is still in progress as of the writing of the report, and analysis and reporting will take place later in 2022.The remainder of this section presents findings from the participant interviews.

Participant Interviews Findings

In Fall 2021, the Evaluation team conducted in-depth interviews with seven Small C&I Initiative participants who were either the business owner or a key decision-maker related to the business. The subsections below describe how customers heard of and then decided to participate in the initiative offering, followed by installation experiences, heat pump use experiences, and overall initiative experiences and satisfaction. Additional details are available in the *C&I 2021 Cold Climate Heat Pump Pilot Customer Interview Results Presentation* submitted as part of Consumers Energy's 2021 reconciliation.

Decision-Making Processes

The Evaluation team asked participants about their awareness and understanding of heat pump technology, their plans to replace existing heating equipment, as well as their concerns, considerations, and motivations for installing the heat pumps.

Participants in the Small Commercial initiative were generally not familiar with heat pumps prior to being contacted by Consumers Energy staff. Over two-thirds of respondents (71%; n=5) were *not at all familiar* with heat pumps prior to the initiative. One respondent said they were *somewhat familiar* and had read some articles about heat pumps, but not enough to have purchased a heat pump without the support from the initiative. Another respondent said they were *very familiar* with the technology, but was under the impression that heat pumps were not suitable for Michigan winters.

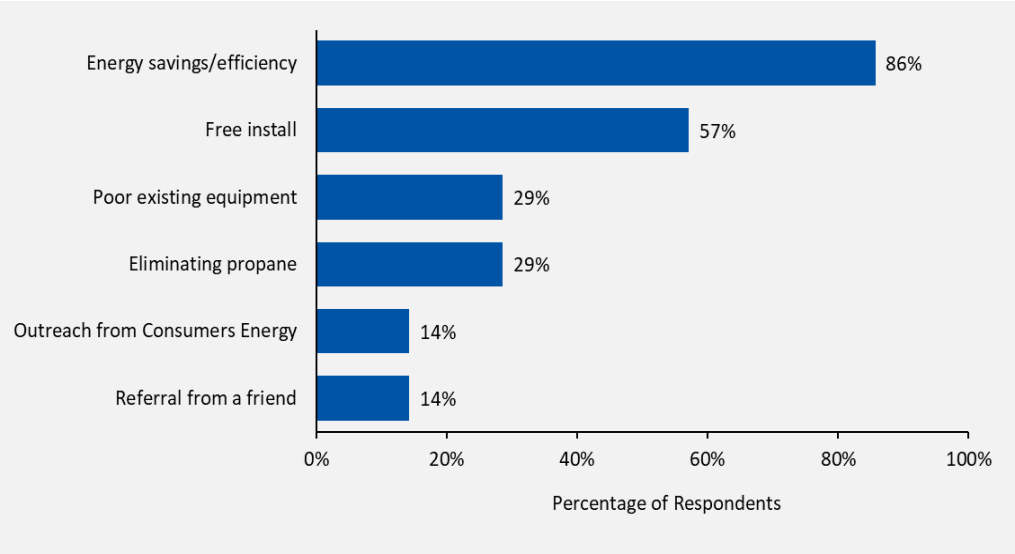
When asked about their existing heating and cooling equipment, all respondents reported having a propane furnace prior to installing their heat pumps, and 86% (n=6) had central AC. While four respondents had no immediate plans to replace their existing equipment, 43% (n=3) had planned to replace their heating equipment within the next one to three years, and all three would likely have replaced their furnace with a new propane furnace. This finding suggests that customers likely would not have considered a heat pump as an option if not for the initiative, despite some respondents reporting low satisfaction with their propane service.

When asked about their concerns and considerations when deciding to install a heat pump, respondents were primarily concerned about cost and technical considerations, while two respondents (29%) initially thought the offer was a scam: one said, “My main thing was, to be honest, I was scratching my head if it was too good to be true. I was suspicious; there are so many scams. My biggest concern [was that] I just wasn’t quite sure what was actually going on. It’s quite a good deal to get that kind of equipment.”

Respondents’ cost considerations included not knowing how much more money they would pay by switching to a heat pump, as well as how much lower their energy bill would be and how much less energy they would use. Three respondents also expressed concerns about how reliable the heat pumps would be during the winter. The following quote exemplifies this sentiment and demonstrates how this hesitancy is related to a lack of knowledge about CCHPs: “…Without knowing about the technology, we were a little concerned…about how well would the systems work in the really cold weather.”

When asked what motivated them to install their heat pump, respondents reported several motivations, mainly saving energy and the free installation, followed by the fact that the cost was largely if not completely covered by Consumers Energy (Figure 24).

Figure 24. Respondent Motivations to Install Heat Pumps



Source: Heat Pump Commercial Interview Guide Question C4. "What motivated you to agree to install the heat pump?" (n=7; multiple responses allowed)

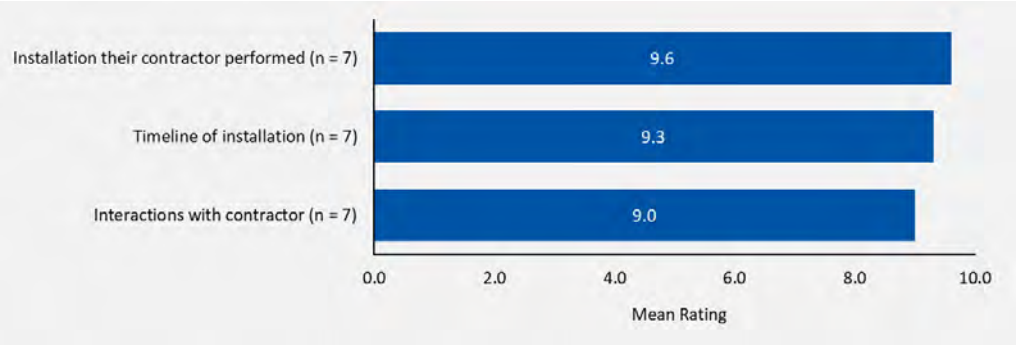
Installation Experiences

The Evaluation team also asked respondents about their experiences with finding a contractor and with having the heat pump installed. All respondents reported that it was easy to find a contractor, and none asked for multiple bids. About half of respondents (43%; n=3) preferred to use their own contractor and one respondent (14%) asked a friend who had also participated in the initiative for their contact. The other three respondents (43%) relied on contractor contacts provided by Consumers Energy: two chose a contractor they were familiar with from the list (and, as mentioned previously, Consumers Energy tailored this list to include trade partners they knew had experience with heat pumps). These findings indicate that the initiative resources for finding a contractor were effective.

Overall, respondents reported having a positive experience with their contractor, with 86% (n=6) saying they would use the same contractor again. All the respondents also reported that the contractors they worked with appeared to be knowledgeable about heat pumps, and 57% (n=4) said the contractor was *very knowledgeable*: "Extremely [knowledgeable] and very helpful and explained it all to me very well… They were fast, efficient, and did exactly what they were going to do in the time they said they were going to do it. They did a great job."

Average satisfaction with contractor interactions was a 9 on 10-point scale, where 1 meant *unacceptable* and 10 meant *outstanding* (as shown in Figure 25). Though respondents were generally satisfied with their contractors, two of the seven respondents (29%) expressed some dissatisfaction. One of these respondents specified that the contractor should have been more communicative about the project schedule and timeline but said they would still hire the contractor again because they would not know who else to hire. The other respondent was less satisfied with their interactions with the contractor and were not sure they would hire them again.

Figure 25. Installation Experiences Satisfaction Averages



Source: Heat Pump Commercial Interview Guide Questions G1a, G1b, and G1d. Please see *Appendix F* for specific question wording.

Respondents were also satisfied with the timeline of their installation. While about half of respondents (57%; n=4) reported some delay with their project timeline, it did not impact their overall satisfaction. However, some reported that if the installation had occurred during a time when they needed their heating or cooling, they would have been more dissatisfied. Heating or cooling needs were not pressing since these customers either had working equipment or their installation was completed in the shoulder season, as evident by the following statements:

- "It might have been different if we didn't have heat or air and every day was a struggle, but it was early spring… so it wasn't an issue, so we weren't pressed to hurry up and get this into service."
- "I'm glad they didn't do it in the winter, because then I would have been irritated [with the delayed project timeline]."

Most of the heat pump installations went smoothly, with respondents rating their satisfaction with the installation process as an average of 9.6 out of 10, as shown in Figure 25. When asked if there were any challenges with installing their heat pump, only two respondents reported some minor challenges related to the equipment not functioning properly at first and unforeseen installation issues. All respondents said that they received a new thermostat as part of their CCHP installation, and about half (43%; n=3) required new duct work. Slightly more than half of respondents (57%; n=4) reported that they have a back-up heating system in addition to the CCHP system. Of those four, two kept their old heating and cooling equipment, one just kept their old back-up heating, and one installed a new propane furnace as a back-up.

Experiences Using Heat Pumps

Due to the timing of this initiative and the research effort, respondents had primarily used their heat pump during the summer months and had used only the cooling function; however, some respondents (71%; n=5) reported that the heating function had come on during colder mornings in September or said they had been able to use the heat briefly in early spring. In general, respondents were very satisfied with their new heat pump and its operation, with an average satisfaction rating of 9.3 out of 10. While respondents were already generally satisfied with the equipment, a few customers noted being hesitant

to give the heat pump a higher rating until after using the heating function more consistently in colder weather. The Evaluation team conducted follow up interviews with Small Commercial initiative participants as part of on-site impact evaluations completed following the 2021/2022 winter heating season to assess participant experiences with the heat pumps in cold weather. [17]

Despite high satisfaction with heat pump performance, almost half of respondents (43%; n=3) reported some minor issues with their heat pumps, including not cooling down to the expected temperature and two issues with the installation that required a contractor to fix. The biggest challenge customers reported was needing to learn how to use their new smart thermostat; this finding was echoed in the winter heating impact analysis, which revealed that some customers would benefit from additional training or support to optimize heat pump controls and settings to maximize savings. These findings suggests that customers easily adapted to their new technology but could use some higher touch support during the first few weeks or months after installation to confirm that all the equipment is performing well and that the customer knows how to use the equipment properly.

Initiative Experiences and Satisfaction

When asked about their overall initiative experience, most respondents said they were *very satisfied* with their participation in the initiative. Most respondents (86%, n=6) had initially learned about the initiative offering from Consumers Energy staff and all seven reported that they had received excellent support throughout their participation. While respondent motivations for deciding to participate in the initiative included the fact that the equipment and installation were free, the support and persistence from Consumers Energy staff was also a motivating factor.

> "Just the willingness that they had to do this for just a small [facility] was huge […] People don't just give stuff away, and [a new heating system] was definitely something that was needed, and we would have had to purchase it in the future."
>
> -Respondent

Respondents' overall satisfaction with the pilot was an average of 9.9 out of 10, and 86% of respondents (n=6) *strongly agreed* that Consumers Energy made it easy to participate in the initiative. When asked if they were likely to recommend Consumers Energy to a friend or colleague if they had a choice in energy providers, most respondents (71%; n=5) said they were extremely likely to do so. The two respondents who gave lower ratings said that it was only because their utility is not something they really think or talk about. One satisfied respondent compared Consumers Energy to the utility that provides electricity at their home: "I've always had great service with Consumers [Energy]. I've had less outages and …anything I need for my business, I'm able to get immediate responses."

Appendix A. Survey and Interview Methodology and Details

This appendix provides survey and interview details and methodologies by initiative or stakeholder.

Contractor Interviews

Consumers Energy provided the Evaluation team with a sample of 177 contractors who had engaged with Consumers Energy HVAC energy waste reduction offerings at some point, but who had not participated in the CCHP Initiatives. The sample did not include any information regarding the number or type of projects completed by the contractor, so the Evaluation team was unable to stratify the sample in any meaningful way. As such, recruitment of contractors proceeded randomly until research quotas were satisfied. We interviewed a total of 11 contractors for this research.

Table A-1 includes contractors' company information such as type, number of projects per year, and products offered.

Table A-1. Interviewed Contractor List

Company Location	Customer Base	Number of Projects/Year	Average Heat Pump Installation/Year
Ada	Primarily residential, more high-end homes	~100	<5 ducted systems >20 mini-splits
Allen Park	Residential multifamily, some single family, very little commercial	1,000–1,500	75 since last fall
Allendale	Data not collected	Data not collected	Data not collected
Benzonia	90% to 95% residential, lots of big homes on shore of Lake Michigan used as seasonal residences; a little bit of multifamily, a little low income	200 installs	20–30
Dearborn Heights	Mostly residential, some multifamily	100	3 last year
Jackson	50% residential, 50% commercial	200–225	6–8 ducted systems >50 mini-splits
Livonia	Primarily (75% or more) income-qualified multifamily, with client that is the largest affordable housing provider in Michigan	5–10 projects per year 100–300 pieces of equipment	10–20 mini-splits per year (primarily server rooms and elevator machine rooms)
Okemos	60% residential and 40% commercial, lots in the city, also lots of dual-fuel applications with propane and lots of air-to-air and geothermal projects	~1,000	~100 in 2020, 80% air-to-air 24 mini-splits in the past year
Parma	Residential and some multifamily (very little commercial)	150–200 pieces of equipment	<10
Sparta	75% residential, commercial is mostly service maintenance, with a rare design/build	~100	12–15 per year for ASHPs and mini-splits.
Warren	50% residential and 50% commercial	200	<5

Distributor and Manufacturer Interviews

The Evaluation team interviewed five distributors and two manufacturers involved in the production and distribution of CCHPs (including mini-split heat pumps) in Michigan. We fielded the interviews via telephone, and each took 30 to 45 minutes to complete. The team recorded and transcribed each interview to assist with our analysis. To motivate manufacturers and distributors to participate, we offered a $75 incentive to each respondent in the form of an Amazon, Target, or Meijer gift card or a donation to a local United Way.

Sampling

For this effort, the Evaluation team specifically targeted manufacturers who have supplied equipment for Consumers Energy programs and associated distributors in Michigan that supply CCHPs produced by these manufacturers. The list of manufacturers and distributors interviewed is shown in Table A-2.

Table A-2. Interviewed Distributor and Manufacturer List

Company Type	Role of Interviewee	Primary Brands Offered	Primary Types Offered	States/Regions Served
Manufacturer	Manager, Utility & Efficiency Programs	(Confidential)	Mini-split	Central U.S.
Manufacturer	Regional Representative	(Confidential)	Mini-split	MI, OH, PA, WV
Distributor	President	Robur	Absorption	MI, OH, IN
Distributor	Director of HVAC Services	Mitsubishi, Rheem, Trane	Mini-split	MI, OH, Eastern U.S.
Distributor	Territory Manager	Trane, Mitsubishi	Mini-split, unitary	MI
Distributor	Regional Sales Manager	LG, Rheem, Bosch	Mini-split, unitary	MI, OH, IN, PA, WV
Distributor	Owner	Daikin, Amana	Mini-split, unitary	MI, WI, IL, IN, OH, PA

The team sampled distributors from a contact list provided by Consumers Energy staff as well as from internet searches for distributors associated with key manufacturers. Additionally, the Evaluation team asked for referrals for distributors during interviews with contractors. We targeted distributors such that representation across manufacturers was roughly equal (ensuring that interviewed distributors do not represent one manufacturer more than another).

Recruiting

The Evaluation team reached out to manufacturers and distributors by phone to schedule interviews. During phone recruitment, we explained the research and provided an Evaluation team contact person so the organization could reach out if they had additional questions or were interested in scheduling an interview. The team primarily used email to recruit referrals, which similarly included an explanation of the research and a request for scheduling an interview.

Profile of Distributors and Manufacturers

Table A-2 above shows respondent information including company type, the role of the interviewee at the company, primary brands offered, types of CCHPs offered, and regions served. Most interviewees represented mini-split CCHP technology and were responsible for operations in several states.

Residential Market Rate Participant Surveys

The Evaluation team sent a survey invitation to the census of 29 Residential Market Rate pilot participants in November 2021. The email survey invitation included a $15 incentive for taking the survey. The Evaluation team sent two reminder emails; after one week and after two weeks. Nine of the 29 participants completed the survey, for a 31% response rate: with such a small sample size, the results should be interpreted with caution and only viewed as directional indications (not intended to be analyzed with statistical confidence).

Income Qualified Multifamily Property Manager and Owner Interviews

The Evaluation team conducted in-depth telephone interviews with three site contacts (a construction manager, a resident manager, and an owner) in November 2021. Each interview lasted approximate 30 minutes. We targeted owners and managers of income-qualified multifamily properties who had participated in the Consumers Energy Income Qualified Multifamily initiative. Franklin Energy provided PMO contact information, including email address and phone numbers, for Evaluation team outreach and recruitment.

The Evaluation team initially distributed emails to six property site contacts and attempted phone recruitment for the seventh due to a missing email address. Though the team made three email attempts, the emails did not result in any successful recruitment for the interviews. The Evaluation team then pivoted to making recruitment calls from Monday through Friday, mid-morning to early evening, calling each number a maximum of five times.

With an interview target for a census (seven) of participating PMOs, the actual number of three interviewed PMOs was consistent with expectations, even with an increased incentive of $150 to make the interview more attractive for potential participants.

Income Qualified Single Family and Multifamily Participant Surveys

The Evaluation team collected feedback from 32 multifamily tenant surveys in November 2021. The email survey invitation included a $15 incentive for taking the online survey. We targeted tenants of income-qualified multifamily properties who had participated in the Consumers Energy heat pump offering. The Evaluation team did not have access to participating tenant contact information, so we attempted to identify tenants through two distinct efforts. First, the team relied on existing income-qualified tenant records to match CCHP properties based on physical address. Using this approach, the team identified 46 potential income-qualified multifamily tenants to recruit. Second, during the team's interviews with multifamily PMOs, we asked and all three PMOs if they were willing to distribute the survey recruitment email to their tenants. This second approach resulted in the potential for 90 additional tenant respondents, though the Evaluation team is unsure of the final count of emails distributed by the PMOs.

The Evaluation team solely relied on email distribution to recruit tenants for the online-only survey. Though the team made three email attempts for the address-matched income-qualified tenant group, the emails combined with the PMO email recruitment effort resulted in 32 successful recruitments for the surveys, for a response rate of 24% (32 of 136).

CADMUS

Small Commercial Participant Interviews

The Evaluation team conducted in-depth telephone interviews with seven business owners and decision-makers in September and October 2021. Each interview lasted approximately 30 to 45 minutes and we offered respondents a $75 gift card for their time. We targeted owners and decision-makers of small commercial and industrial facilities (<20,000 square feet) who had participated in the Consumers Energy Small Commercial initiative offering. Consumers Energy provided these decision-makers' contact information, including email address and phone numbers, for Evaluation team outreach and recruitment. The interview guide was reviewed and approved by Consumers Energy staff to ensure that questions were consistent with their expectations and reflected the issues of interest to Consumers Energy.

The Evaluation team recruited customers via email and phone. Due to the small sample size of nine participants, we attempted to recruit the entire sample with a minimum goal of five completes. The Evaluation team was able to recruit seven of the nine participants, with a response rate of 78%. An eighth participant was interested in participating but their heat pump had not been installed yet, so they were not able to answer questions about the full experience. The ninth participant was unreachable after a total of five contact attempts via email and voicemail.

CADMUS

Appendix B. Impact Analysis Methodology and Details

This appendix provides the methodology and details related to the Residential Market Rate pilot engineering analysis and the Income Qualified Multifamily initiative billing analysis.

Market Rate Engineering Methodology

The Evaluation team conducted an engineering analysis of the impacts from the Residential Market Rate pilot and relied on MEMD assumptions and information we had collected on customer data such as such as home vintage, presence of central cooling, installed system COP at 5°F, rated HSPF and SEER, tonnage, and other data. The Evaluation team relied on the MEMD weighting tool, which generates single measure outputs based on home vintage, climate zone, sizing, and efficiency levels.

The MEMD building simulation data provided end-use level consumption details broken out by the seven Michigan climate zones (Alpena, Detroit, Lansing, Muskegon, Saginaw, Sault Ste. Marie, and Traverse City) and three building vintages (old, average, and new). The Evaluation team used the MEMD building simulation end-use consumptions for ASHP heating, ASHP electric resistance back-up heating, and ASHP cooling to calculate pre– and post–CCHP equipment consumption on a per-ton basis. We then adjusted these end-use consumptions using COP from ASHP federal standard HSPF and SEER values to reflect site-specific equipment. We used several types of CCHP-collected site data in the analysis:

- Home vintage
- Presence of central AC
- Home heating fuel type
- Home heating equipment type
- Premise zip code
- CCHP details: quantity, COP at 5°F, HSPF, SEER, and tons

Since existing space heating equipment data collection was limited to fuel type, the team assumed that existing equipment represents federal standard equipment (in AFUE) and represents a 50/50 average of boilers and furnaces, if applicable. The Evaluation team created this split because the data field for system type collected was either “Furnace/Boiler” or “Resistance.” The difference in federal standard efficiency is minimal: 0.8 for furnaces and 0.82 for boilers. Therefore, the team used 0.81 AFUE.

We also assumed that existing central cooling equipment represents the federal standard SEER value. For homes without central cooling, we assumed that a portion of homes use room or window AC units to provide a portion of cooling, and we based this portion of homes on *2015 Residential Energy Consumption Survey*[18] data for the East North Central census division. The Evaluation team used data

[18] U.S. Energy Information Administration Residential Energy Consumption Survey 2015 Data Website: https://www.eia.gov/consumption/residential/data/2015/

from the Consumers Energy 2021 *Electric Energy Waste Reduction Potential Study*[19] to develop a ratio of room AC tonnage for single family homes when compared to a central system (since the room AC unit likely did not provide cooling load equivalent to the CCHP system). Like with central ACs, we assumed the room AC efficiency to represent the federal standard EER value.

Since no sizing information was collected on the sites about the existing HVAC systems, the Evaluation team assumed equivalent kBtu per hour heating or cooling tonnage as the CCHP, except for existing room AC sizing (for which we made an adjustment). Therefore, results only reflect offset heating and cooling load by the CCHP, and not total household heating and cooling load.

We used two data points to map MEMD 2019 data to the site-specific data: "Approximate House Age" and "Premise Zip." The household age was a one-to-one match with MEMD vintages, and therefore was a simple mapping lookup. The Evaluation team mapped the zip codes nearest to the available MEMD weather station based on distance and engineering judgment for weather impacts. With these two site-specific data points—vintage and zip code—we were able to map the MEMD 2019 building simulation consumptions to each specific site.

To adjust the MEMD 2019 ASHP end-use consumptions to reflect the existing equipment on a per ton basis, the team applied COP adjustments using the federal standard definitions outlined above. To adjust the MEMD 2019 ASHP end-use consumptions to reflect the CCHP equipment, we performed a more detailed analysis (as additional equipment data was available). Using typical meteorological year version 3 (TMY3) 8760 hourly data for each MEMD modeled reference city, we performed hourly bin analysis to determine hours based on temperature bins in 5°F buckets. Assuming the HSPF value reflected performance at 47°F, the team developed a linear relationship using the COP at 5°F system performance data. We capped this linear relationship during cold temperatures to not be less than 1 COP, representing 100% electric resistance performance. Using the hourly bin analysis data by 5°F buckets and assuming CCHP heating did not occur above 65°F, the Evaluation team developed a weighted average CCHP HSPF efficiency to represent annual heating performance of the CCHP specific to the unit installed. We then used the weighted average CCHP HSPF and SEER values to adjust MEMD 2019 ASHP end-use consumptions to reflect CCHP performance on a per-ton basis. In order to represent total heating and cooling load, we multiplied the CCHP installed tonnage by the pre/post heating and cooling loads per ton.

The Evaluation team relied on Consumers Energy 2021 residential natural gas and electric marginal rates (per kilowatt-hour and per therm), which include all surcharges for single-family customers. The team used previously developed load shapes to reflect equipment usage during peak and non-peak periods for the electric bill impacts. We created annual electric fuel costs by applying each specific equipment type's consumption load shape to the peak and off-peak rates. For fuel oil and propane costs, the

[19] 2021 Energy Waste Reduction Electric Potential Study Report: https://cadmus.sharepoint.com/sites/collaboration/6409-P01/ces/Shared%20Documents/Final%20Reports/2021/Electric%20Potential%20Study/2021%20Energy%20Waste%20Reduction%20Electric%20Potential%20Study%20Report%20FINAL%202021.06.10.pdf

Evaluation team used the latest Michigan monthly data from U.S. Department of Energy resources. These fuel costs utilized in the impact analysis are shown below in Table B-1.

Table B-1. Market Rate Fuel Costs Utilized in Impact Analysis

Fuel Type	Cost
AC_Central Loadshape - Electricity with Surcharge	$0.18
AC_WallWindow Loadshape - Electricity with Surcharge	$0.18
ASHP Loadshape - Electricity with Surcharge	$0.17
ZONAL_ER_HEAT Loadshape - Electricity with Surcharge	$0.16
AC Central Load Shape - Electricity with Surcharge	$0.18 per kWh / $52.48 per MMBtu
AC Wall Window Load Shape - Electricity with Surcharge	$0.18 per kWh / $52.19 per MMBtu
ASHP Load Shape - Electricity with Surcharge	$0.17 per kWh / $48.57 per MMBtu
Zonal Heat Load Shape - Electricity with Surcharge	$0.16 per kWh / $48.18 per MMBtu
Propane	$2.44 per gallon / $26.71 per MMBtu
Fuel Oil	$3.10 per gallon / $22.56 per MMBtu
Natural Gas	$7.91 per thousand cubic feet / $7.62 per MMBtu

Electric and natural gas rates used from Consumers Energy.

Multifamily Billing Analysis Methodology

To estimate electric energy usage changes within the Income Qualified Multifamily initiative projects, the Evaluation team designed and conducted a statistical billing analysis. The team relied on historical advanced metering infrastructure (AMI) interval data to estimate facility-wide and per-tenant-unit savings associated with CCHP installations using the Princeton Scorekeeping Method. The team incorporated TMY3 data to normalize usage and control for weather. We also included a nonparticipant comparison group, selected from other income-qualified electrically heated multifamily nonparticipants to control for the impacts of nonprogrammatic factors (such as changes in economic conditions including COVID-19–related behavior changes).

Data Sources

The Evaluation team requested and compiled participant and household data for the CCHP billing analysis from several sources:

- ***Heat pump initiative tracking data.*** The team received initiative tracking data from the implementation contractor to identify CCHP properties. These initiative tracking data included all participants from March 2020 to December 2020, including property name, participation dates, building square footage, and heat pump efficiency and capacity ratings. The tracking data did not include specific tenant unit addresses or the specific account information connected with each tenant.
- ***Multifamily composite database.*** The team developed a multifamily database to identify multifamily properties based on property size for prior 2020 evaluation research, which we used to identify all unique addresses (and all accounts associated with each property), including tenant units.

- ***Electric AMI data.*** Consumers Energy provided electric AMI data for all properties that had identifiable account data. This included meter read dates and times and all kilowatt-hour usage, by account, between June 2019 and September 2021.
- ***Michigan weather data.*** The team collected average hourly temperatures from June 2019 through September 2021 for four weather stations corresponding to the nearest monitoring station locations associated with CCHP participants. We matched hourly heating degree hours (HDHs) and cooling degree hours (CDHs) to AMI data read dates and times, and compiled hourly TMY3 15-year normal weather averages from 1991 through 2005 from the National Oceanic and Atmospheric Administration to assess energy usage under normal weather conditions.

Data Processing

The Evaluation team conducted several data processing steps to review, validate, and transform the raw AMI and tracking data into an analysis dataset:

- Imported and cleaned the tracking, AMI, and weather station datasets into Statistical Analysis System software
- Merged tracking and AMI datasets using account ID
- Filled in missing or zero AMI data readings with averages based on similar day-types or as the average of the previous and following hours
- Checked the hourly AMI histories for problems such as vacancies, outliers, and too many missing/interpolated readings
- Mapped each property to the nearest weather station using the property zip code
- Used hourly temperatures to determine variable base HDHs and CDHs for each station
- Merged the HDHs and CDHs onto the AMI and tracking data, using respective dates and times for each account
- Matched TMY3 HDHs and CDHs from the nearest station to weather-normalize the AMI data

Participant and Nonparticipant Groups

For the AMI analysis, the Evaluation team assigned properties into participant and nonparticipant groups. To be selected for the participant group, all multifamily heat pump properties had to have a continuous nine-month period of available usage data both before and after their participation in the pilot. The team used a rolling specification to assign pre- and post-periods, identifying a range of months around the installation period for each participant. Starting with a census of participants from the March through December 2020 period (initially seven properties), the Evaluation team identified a final participant group for analysis (after screening for participants who had at least nine months of pre-period and post-period billing data). We conducted account-level reviews of pre- and post-period usage for all individual participants to identify anomalies (periods of vacancies or other anomalies) that could bias the results. The team also applied additional screening criteria, described in detail in the *Data Screening and Model Attrition* section.

The team used a comparison group of nonparticipants to account for exogenous factors that may have occurred coincident with heat pump initiative activities. These factors can include macroeconomic effects, COVID-related behavior or occupancy changes, or other interactions that may have affected energy usage outside the heat pump influence. The Evaluation team identified comparison groups using customers who we had identified as living in income-qualified electrically heated multifamily properties. After creating the eligible group of nonparticipants, we further refined the nonparticipant group by matching each property to a participant property based on pre-installation usage. This assisted us in creating groups with baseline usage profiles as similar as possible to those of participants.

Disaggregation

Consumers Energy had the Evaluation team focus the heat pump analysis on electric-heated properties to create savings associated with reducing electric heating and cooling loads. Because of the focus on electric heating and cooling loads, the Evaluation team disaggregated the billing data to isolate the weather-sensitive electric heating and cooling usage from overall annual electric usage (which may include water heating, cooking, plug load, and lighting usage). First, we estimated weather-normalization models for each customer in the pre- and post-installation periods using actual observed weather data. Then we estimated the weather-sensitive components of electric usage using TMY3 data. Finally, we estimated the heating- and cooling-related components of usage.

Data Screening and Model Attrition

Data anomalies, outliers, missing data points, incomplete records, and other data issues all introduce potential bias into a billing analysis. The Evaluation team used several rules to flag and then remove accounts that failed to meet certain conditions:

- ***Must have sufficient pre- and post-installation billing data for analysis.*** All accounts had to contain a minimum of nine months of pre- and post-installation usage data.
- ***Must have a pre- and post-installation change within 70%.*** All accounts showing post-installation usage changes of up to 70% of pre-installation usage were retained in the analysis.
- Must not be an outlier or vacancy. The Evaluation team performed account-level reviews of pre- and post-installation period usage for all individual participants and removed anomalies (such as periods of vacancies) that could bias the savings results. We also removed units that participated in another energy-efficiency program from the analysis, as we could not determine which project created the observed savings.

The data screening resulted in a final analysis sample of three unique participant properties representing 77 tenant units. This corresponds to just under half (43%) of the original participating properties. As shown in Table B-2, the largest source of attrition for the billing analysis of participants originated from removing vacancies from the analysis, primarily because the billing data was only available for accounts that were active at the time of the request. Many of the accounts that were currently active did not have the necessary historical usage data at the apartment unit level to be included in the analysis. For the nonparticipant group, the single largest source of attrition resulted from units that did not show an electric heating signature.

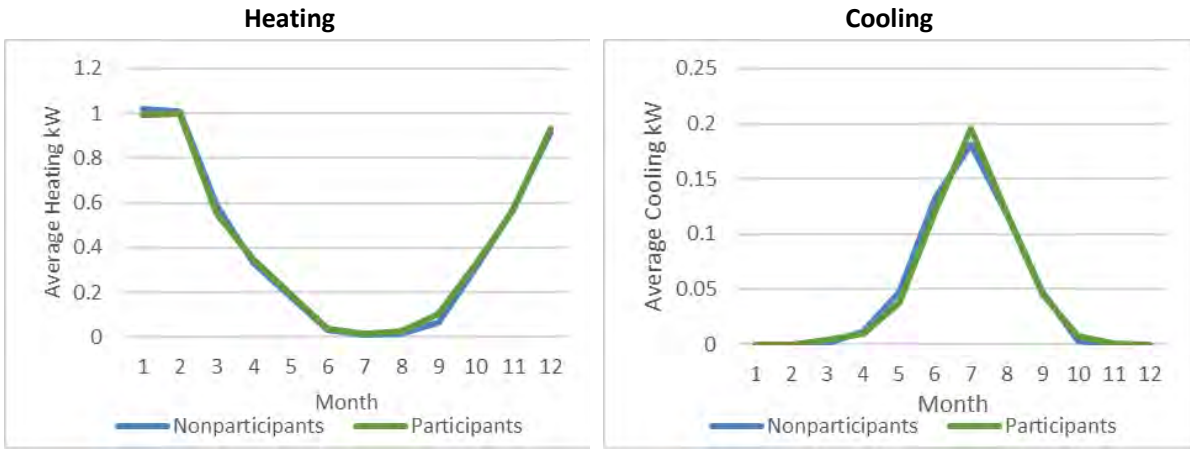
Table B-2. Income Qualified Multifamily Heat Pump Billing Analysis Summary Attrition

Screen	Participants	Nonparticipants
Initial Requested Sample	**97**	**2,329**
AMI Data Available	96	2,308
Sufficient Pre-Post Data	94	2,192
Removed Outliers/Vacancies	84	1,733
Matched Nonparticipant Property Type to Participant Property Type (such as removed high rise and mobile homes)	84	1,583
Determined that Dwelling Used Electric Heating	84	145
Passed Pre-Post Hourly PRISM Models/Hourly Prediction	84	132
Change within 70%	77	119
Matched Usage to Participants	77	112
Final	**77**	**112**

Baseline Electric Energy Use

Baseline multifamily building electric usage—the whole-building electric usage before installing energy-efficiency upgrades—is a critical input to whole-building energy savings estimation for electric-heated properties. The Evaluation team, using hourly PRISM (Princeton Scorekeeping Method) weather normalization and energy load disaggregation models, estimated the annual and monthly heating and cooling loads for the Income Qualified Multifamily participating tenant units. Additionally, estimating baseline heating and cooling energy usage across both participating and nonparticipating tenant units allows for isolating initiative-induced impacts specific to heat pump installation. This is important, as it accounts for non-programmatic influences on energy use, controlling for occupancy changes, behavior changes, changes attributable to COVID-19, and any other non-programmatic changes. A summary of the monthly average heating and cooling loads (in average kilowatts) across the participants and nonparticipant groups is shown in Figure B-1. There is little discernable difference—and, more importantly, no statistically significant difference—between participants' and nonparticipants' monthly heating and cooling loads.

Figure B-1. Baseline (Pre-Installation) Annual Heating and Cooling Load



The Evaluation team, with access to tenant apartment electric usage, estimated an average weather-normalized pre-installation baseline tenant unit usage of 3,860 kWh. Table B-3 shows the breakdown of the heating, cooling, and annual baseline pre-period annual weather-sensitive usage (per tenant apartment). As expected, given that multifamily tenant units in the CCHP were electrically heated, heating electric energy use is the predominant component (approximately 94%) of annual weather-sensitive use in these units.

Table B-3. Participant Tenant Unit Pre-Period Baseline Electric Weather-Normalized Per-Unit Usage

Usage Type	Weather-Sensitive Annual Usage (kWh)	Heating Usage (kWh)	Cooling Usage (kWh)
Billing Analysis	3,860	3,626	234

Source: Evaluation team AMI billing analysis.

Assess Change in Energy Use

As the final step in the analysis, the Evaluation team estimated real world changes to energy use between pre-and-post-installation usage patterns for participants and nonparticipants. Energy savings are the difference between participants' and nonparticipants' energy usage between the pre- and post-installation periods.

Engineering Calibration and Validation

The Evaluation team benchmarked the billing analysis findings relative to values produced from a simplified heat pump engineering model and the initiative-claimed savings (the initiative relied on current MEMD savings estimates). The goal of benchmarking was to help frame the billing analysis findings and understand how close the changes to energy usage tracked with alternative sources. The Evaluation team compiled initiative tracking claimed savings from eTracker and normalized the savings at the tenant apartment unit level by using the total number of installed heat pumps, the claimed savings, and the total number of apartment units. The team relied on the heating load requirement (3,626 kWh), assumed a CCHP COP of 2.75, and entered this data into a simple algorithm expressing continued baseboard heating, CCHP heating, and total heating demand based on several different displacement scenarios (Table B-4).

Table B-4. Cold-Climate Heat Pump Simplified Engineering Estimate

DHP Heating Load Displacement	Baseboard kWh	CCHP with COP of 2.75 (kWh)	Savings (kWh)	Total kWh
100%	-	1,319	2,307	3,626
75%	907	989	1,731	3,626
50%	1,813	659	1,154	3,626
36%	2,319	475	832	3,626

Bill Savings Estimation

To estimate the bill savings attributable to the CCHPs installed in the multifamily tenant units, the Evaluation team estimated the bill savings occurring during the time-differentiated bill periods across the year. According to residential rate data, peak period rates occur in summer months, from May 1 through September 30, during weekdays from 2 p.m. to 7 p.m. The Evaluation team then estimated the savings occurring during the peak and off-peak periods. Table B-5 shows a summary of the seasonal peak and off-peak rates and savings.

Table B-5. Cold-Climate Heat Pump Bill Savings Calculations

Residential Rate	Residential Billing Rate ($)	Income Qualified Multifamily CCHP Savings Occurring During Each Period (kWh)	Bill Savings ($)
Summer Peak	$0.213	6.1	$1.30
Off-Peak	$0.164	889.9	$145.94
Total Bill Savings			**$147.24**

Electric Savings: Engineering Comparison

The Evaluation team developed a simplified engineering estimate to compare how the evaluated electric savings compared with anticipated savings from a CCHP and added the initiative-claimed savings based on MEMD measures. Table B-6 shows a comparison of Income Qualified Multifamily initiative savings from the billing analysis sample, two engineering estimates based on two different displacement scenarios, and the initiative MEMD claimed savings estimate. The billing analysis estimate showed lower realized savings relative to the engineering estimate (assuming 50% of the electric baseboard heating was displaced by the CCHPs) and the MEMD estimate. In order for the engineering estimate to match the billing savings estimate of 832 kWh of heating load savings, the CCHPs would need to displace just over one-third (36%) of the heating load, which therefore assumes that the legacy baseboard heating systems still account for the majority of heating load for the apartments. The continued use of baseboard heat is consistent with feedback from the tenant survey, in which tenants reported continued use of baseboard heat as their primary heating source.

Table B-6. Annual Per–Tenant Unit Cold-Climate Heat Pump Electric Weather-Sensitive Savings Estimates Comparison

Source	Weather-Sensitive Usage (kWh) (A)	Weather-Sensitive Savings (kWh) (B)	Savings versus Weather-Sensitive Usage (%) (B / A)
Billing Analysis	3,860 (Annual)	896	23.2%
Billing Analysis	3,626 (Heating)	832	22.9%
Engineering @ 50% Displacement [a]	3,626 (Heating)	1,154	31.8%
Engineering @ 36% Displacement [a]	3,626 (Heating)	832	22.9%
MEMD/Pilot Claimed Savings [b]	3,860 (Annual)	1,474	38.2%

[a] This is an engineering estimate based on the heating season only and derived from AMI billing analysis.

[b] This represents annual weather-sensitive usage from the AMI billing analysis.

CADMUS

Appendix C. Consumers Energy Heat Pump Market Rate Customer Survey

Objectives	Research Questions	Question Number
Assess customer awareness and motivations to install heat pumps	Were participants aware of heat pumps prior to participating in the offering? How do customers learn about heat pumps? What are participants' motivations for installing a heat pump? What are important decision factors for installing a heat pump? How much rebate is required to motivate participation?	Section B
Assess participant installation experience	How did participants experience the installation? Are there opportunities to improve the installation experience?	D1–D3
Document participant perceptions of heat pumps, energy or cost savings, comfort levels, and satisfaction	What are participants' experiences with heating/cooling comfort? How satisfied are participants with the heat pumps and the offering? How satisfied are participants with Consumers Energy?	D4–D12, B1, B2
	What non-energy benefits did the offering generate (such as reduced bill impacts, enhanced comfort levels, and improved operational issues)?	D11
Document participant usage behavior and home characteristics	How do respondents manage energy use at the thermostat?	Section C
	What are participants' home characteristics?	Section E

Survey Overview: The Evaluation team administered an online survey to residential customers who received a new heat pump. Then the team sent an email with a link to the survey, followed by reminder emails to encourage households to complete the survey withing the desired timeframe. In addition, the Evaluation team offered participants a $15 Meijer or Amazon.com gift card for completing the survey.

Target Audience: Census of Residential Market Rate pilot participants who installed a new heat pump as part of the Consumers Energy heat pump offering.

Survey Introduction and Purpose

Welcome, thank you for taking a few minutes to provide feedback about your cooling and heating equipment. Your feedback is very important to us and will help us improve rebates and incentives for new products that help customers save energy. This survey should take about 10 minutes. Your responses are confidential and will be used for research purposes only.

Be sure to enter your name and address at the end of the survey to receive your $15 Meijer or Amazon gift card as our thanks.

Click on the Next and Back buttons at the bottom of each page to navigate through the survey.

CADMUS

A. *Screener*

A1. Our records indicate that you received a rebate for a heat pump installed in your home. Is this correct?
1. Yes
2. No **[TERMINATE]**
98. Don't know **[TERMINATE]**

A2. Approximately how long have you lived in your current home?
1. Less than one year
2. One to three years
3. Over three years

A3. **[If A2=1]** Were you living in your current home when the heat pump was installed?
1. Yes
2. No **[TERMINATE]**

TERMINATION MESSAGE: This survey is for Consumers Energy customers who received a rebate for a heat pump through the heat pump rebate program and who were living in the home when the heat pump was installed. Thank you for your interest in participating in this survey.

B. *Current Company Metrics and Awareness*

We'd like to ask some questions about your opinions toward Consumers Energy.

B1. How likely would you be to recommend Consumers Energy to a friend or family member if you had a choice in energy providers?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

B2. Please describe in detail why you gave that rating. _____

With these next questions, we would like to know more about your experience with heat pumps.

B3. Were you familiar with heat pumps before deciding to purchase and install the heat pump?
1. Yes
2. No
98. Don't know

B4. **[DISPLAY IF B3=1]** Prior to participating in this offer, had you ever had a contractor recommend a heat pump?
1. Yes, I had a contractor recommend a heat pump
2. No, a contractor has never recommended a heat pump to me

B5. Before you participated in this offer, were you aware that Consumers Energy offered rebates for heat pumps?

1. Yes, I was aware of heat pump rebates
2. No, I was unaware of heat pump rebates

B6. How did you first learn about the heat pump rebate? Please select only one response. **[RANDOMIZE 1–6]**

1. Contractor recommendation
2. Consumers Energy website
3. Consumers Energy flyer or other marketing material
4. Friend, family, neighbor, or colleague
5. Email from Consumers Energy
6. Online search
7. Other (please specify)

98. Don't know

B7. What were the main reason(s) you decided to install a heat pump in your home? (Select up to three) **[RANDOMIZE 1–9]**

1. To reduce energy bills in the winter months
2. To reduce energy bills in the summer months
3. To distribute heating and cooling more evenly throughout the home
4. To add heating and/or cooling for a new or renovated space in the home
5. To replace a broken heating or cooling system
6. To reduce reliance on natural gas or delivered fuels
7. To add cooling (where there was not previously a whole-home system)
8. To take advantage of heat pump incentives (from Consumers Energy and/or my contractor)
9. To take advantage of electricity produced at my home by renewable sources (such as solar or wind)
10. Something else (please describe)

B8. Please rate the importance of the following items on your decision to install a heat pump. **[RANDOMIZE ITEMS]**

Items	Not at All Important 1	2	3	4	5	6	7	8	9	Extremely Important 10	Don't know
a. The amount of rebate from Consumers Energy (up to $1,000)	○	○	○	○	○	○	○	○	○	○	○
b. Recommendation from a contractor	○	○	○	○	○	○	○	○	○	○	○
c. Possible energy savings over the previous heating/cooling system	○	○	○	○	○	○	○	○	○	○	○

B9. Would you have installed a heat pump if Consumers Energy had not offered a heat pump rebate?
1. Yes (I would have installed a heat pump without a rebate)
2. No
98. Don't know

B10. **[IF B9>1]** Would you have installed a heat pump if the rebate had been one-quarter of the value you received (up to $250)?
1. Yes (I would have installed the heat pump with a $250 rebate)
2. No
98. Don't know

B11. **[IF B9>1]** Would you have installed a heat pump if the rebate had been half as much as the amount you received (up to $500)?
1. Yes (I would have installed the heat pump with a $500 rebate)
2. No
98. Don't know

C. *Thermostat Use*

Next, we have a few questions about how you typically use your thermostat to manage the level of comfort in your home.

C1. What type of thermostat do you have in your home? (Select one.)
1. **Non-programmable** thermostat (set temperature manually and it did not change automatically)
2. **Programmable** thermostat with **set-backs programmed** (thermostat set to automatically change temperature at specific times)
3. **Programmable** thermostat—**not programmed** (thermostat has programming capability, but these were not used.)
4. **Basic networked or Wi-Fi–enabled** thermostat (had remote control, but not occupancy sensing or learning features)
5. **Smart learning** thermostat that includes advanced features such as occupancy sensing and schedule learning (examples include Nest, Ecobee, Honeywell Lyric, and Emerson Sensi)
98. Don't know

C2. Who in your household tends to monitor and adjust your thermostat?
1. I mostly monitor and adjust my home thermostat
2. Everyone in my household monitors and adjusts my home thermostat
3. Other members of my household typically monitor and adjust my home thermostat

C3. How did your household **most frequently** manage your thermostat to control the temperature in your home this summer? (Select one)
1. Keep it at a constant temperature
2. Manually adjust the temperature as needed
3. Create customized/programmed settings to automatically change temperatures at different times of the day
4. Allow the smart thermostat to manage the temperature by learning my preferences and/or detecting when home or away
5. Other (please describe)
98. Don't know

C4. Your heat pump offers the ability to use heating and cooling schedules. Did the installation technician setup your heat pump on a heating and cooling schedule?
1. Yes, the installer set up a heating and cooling schedule
2. No, the installer did not set up a heating and cooling schedule
98. Don't know

C5. **[IF C4=1]** Are you still using this heating and cooling schedule?
1. Yes, I have kept the heating and cooling schedule
2. No, I (or someone in my household) turned off the heating and cooling schedule
3. No, I (or someone in my household) changed the heating and cooling schedule to my own
98. Don't know

C6. Have you been provided with instructions on how to set up and control your heating and cooling schedule on your heat pump?
1. Yes, I received instructions
2. No, I did not receive instructions
98. Don't know

D. *Installation and Usage Experience*

Next, we would like to know about your experience with the heat pump.

D1. Our records indicate that the heat pump was installed in your home around **[INSTALLATION-COMPLETE DATE]**. Were you present during the installation of the heat pump?
1. Yes
2. No

CADMUS

D2. Using a rating scale from 1 to 10, where 1 is *unacceptable* and 10 is *outstanding*, how would you rate each of the following installation experiences with the heat pump offering?

Question	Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know / NA
Scheduling a time for installation	O	O	O	O	O	O	O	O	O	O	O
Staying informed about the installation	O	O	O	O	O	O	O	O	O	O	O
[If D1=1] Overall installation time	O	O	O	O	O	O	O	O	O	O	O
[If D1=1] The professionalism of the installation technician	O	O	O	O	O	O	O	O	O	O	O
Education and instructions provided to you about heat pump usage	O	O	O	O	O	O	O	O	O	O	O
Follow-up from the installation technician or Consumers Energy	O	O	O	O	O	O	O	O	O	O	O

D3. **[IF ANY QUESTION IN D2=6 OR LOWER]** If there was something unsatisfactory about the heat pump installation, please describe in detail why you gave that rating.

_____

D4. In general, how did the heat pump affect your home comfort? (Select all that apply)

1. My home is **just as comfortable** as it was previously
2. My home is **more comfortable** than it usually was
3. My home is uncomfortably warm
4. My home is uncomfortably cold
5. My home is **too humid**
6. My home is **too dry**
7. My home was more evenly heated and/or cooled prior to the installation
8. Something else (please describe)

D5. **[IF D1=1 AND COMPLETE DATE IS PRIOR TO APRIL 1, 2021]** How would you rate the heating comfort level provided by the heat pump during winter months?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
O	O	O	O	O	O	O	O	O	O	O

[If D5<6] What concerns do you have about the heat pump's ability to heat to your comfort level?

_____

D6. How would you rate the cooling comfort level provided by the heat pump during summer months?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
○	○	○	○	○	○	○	○	○	○	○

[If D7<6] What concerns do you have about the heat pump's ability to cool to your comfort level?

_____

D7. Taking everything into consideration, how would you rate your overall experience with the heat pump so far?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
○	○	○	○	○	○	○	○	○	○	○

D8. Based on your experiences with the heat pump so far, how likely would you be to recommend it to a friend?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

D9. Based on your experience so far, do you have any recommendations to improve the heat pump rebate offer? _____

98. Don't know

D10. Since the heat pump was installed, have you seen a lower-than-expected energy bill?

1. Yes
2. No
3. Too soon to tell
98. Don't know

D11. In addition to energy savings, if any, are there additional benefits you have experienced or observed from the installation of a heat pump? (Select all that apply) **[RANDOMIZE]**

1. Increased comfort
2. Lower utility bills
3. Improved appearance of my home
4. Improved air quality
5. Improved heating and cooling distribution (across sections of my home)
6. Less maintenance required

7. Improved ability to manage heating/cooling on a schedule
8. Fewer illnesses for household members
9. Other (please specify)
10. Too soon to know **[EXCLUSIVE OF OTHER RESPONSES]**
11. No other benefits **[EXCLUSIVE OF OTHER RESPONSES]**

98. Don't know **[EXCLUSIVE OF OTHER RESPONSES]**

D12. **[If D12=1 AND D11<10]** Considering that the heat pump offering provided both saved energy and some additional benefits to your home, please indicate which was the most important to you:

1. The energy savings
2. The other benefits previously identified
3. The energy savings are equal to the other benefits

98. Don't know

E. *Demographics*

Finally, we have a few questions about your home.

E1. How many people live in your household on a regular basis, year-round?

1. 1
2. 2
3. 3
4. 4
5. 5
6. More than 5

99. Prefer not to answer

E2. Approximately how many square feet of living space does your home have? Do not include the basement unless it is a space that you consider lived in.

1. Under 1,000 square feet
2. 1,000 to less than 1,500 square feet
3. 1,500 to less than 2,000 square feet
4. 2,000 to less than 2,500 square feet
5. 2,500 to less than 3,000 square feet
6. 3,000 to less than 4,000 square feet
7. 4,000 or more square feet

98. Don't know

F. *Closing*

F1. On occasion, managers of the Consumers Energy programs may want to contact a customer to learn more about their participation experience. Please check here if you prefer not to be contacted by a program manager.
1. Do not contact me

F2. Do you have any recommendations for ways Consumers Energy can support you in helping you save energy?
1. Please describe_____

F3. To thank you for your time spent completing this survey, we would like to send you a $15 gift card to either Meijer or Amazon.com. Please choose which gift card you would like to receive.
1. $15 Meijer gift card
2. $15 Amazon.com gift card
3. Neither – I do not wish to receive a gift card

F4. **[IF F3=1 OR 2]** Please provide your name, address, and email to receive your gift card. This information will only be used to mail your gift card.
1. Name:_____
2. Address:_____
3. Address 2:_____
4. City:_____
5. State:_____
6. Zip:_____
7. Email**:** _____

Please click Next to submit the survey.

[END OF SURVEY MESSAGE] Those are all the questions we have at this time. Thank you for your participation in the Consumers Energy heat pump offer.

For more information on energy efficiency, here's where to find it:

- **Want Online Information about Our Other Energy-Efficiency Rebates and Programs?** For details of additional ways Consumers Energy may be able to help you make your home more energy efficient and help you manage your monthly energy bills, please visit us online at ConsumersEnergy.com/myhome.
- **Want to Speak to an Energy-Efficiency Advisor by Phone?** To talk to someone about additional rebates and programs, please contact one of our Energy Advisors at (888) 652-1237.

Appendix D. Consumers Energy Heat Pump Property Owner and Manager Interview Guide

Research Questions

Objectives	Research Questions	Interview Section
Document participant installation experience	How well did the offering manage the user installation experience? Are there opportunities to improve the installation experience?	B1, B3
Document participant usage behavior and experience	How are tenants using and operating the heat pumps? Did customers retain secondary or supplemental heating equipment after the heat pump was installed?	B2, B4
Document awareness and perceptions of heat pumps	What is the current perception of heat pump technologies? Were participants aware of heat pumps prior to being approached by Consumers Energy or the contractor? What are the perceived energy benefits of heat pumps? What non-energy benefits did the offering generate (such as reduced bill impacts, enhanced comfort levels, or improved operational issues)?	C1–C4, E2–E5
Document participant decision-making around participating in the heat pump offering	What key factors affected participants' decisions to install a heat pump? What are the key barriers to adopting heat pumps?	D1–D4
Identify marketing and outreach best practices	How did the participant learn about the offering?	C3
	What are the most effective means of marketing heat pumps?	F1–F3
Assess satisfaction with the offering and with Consumers Energy	How satisfied are property owners and managers with the heat pump offering? How satisfied are tenants with the heat pumps and the offering? How satisfied are property owners and managers with Consumers Energy?	G1–G4

Target Audience: The target audience for these interviews was multifamily PMOs who participated in the CCHP initiatives. The Evaluation team attempted to interview a census of participating PMOs.

A. General Introduction

A1. To begin, please tell me about your multifamily properties.

1. How many unique multifamily properties do you own or manage?
2. How many of them are located in Michigan?
3. Do you own/manage only subsidized or income eligible housing or do you also own/manage market rate properties?

B. Installation and Usage Experience

B1. Please describe your experience, including any positive or negative elements, of the heat pump installation for each of the following installation components (please note if you are not aware of any of these elements):

1. Scheduling a time for the installation
2. Informing the tenants
3. Overall installation time
4. Professionalism of the installation technicians
5. Education and instructions provided to management about heat pump usage
6. Education and instructions provided to tenants about heat pump usage **[PROBE: WERE YOU INFORMED ABOUT PRIORITIZING HEAT PUMP USAGE OVER BASEBOARD HEATING?]**
7. Follow up

B2. Have you received any feedback from your tenants about the new heat pumps? **[PROBE: DO THE COMMENTS TEND TO BE POSITIVE, COMPLAINTS, OR QUESTIONS?]**

B3. Have you had any concerns or issues with the heat pumps installed in your property? **[PROBE: HAVE TENANTS COMPLAINED, DO MAINTENANCE STAFF HAVE ANY FEEDBACK ABOUT THEM?]**

B4. It is our understanding that the existing baseboard heating equipment was left in tenant apartments. Are you aware of whether tenants are continuing to use their baseboard heaters or if they rely mostly on the new heat pumps for heating?

1. Are you aware if the tenants received educational materials or training on the use of the heat pumps? **[PROBE: HAVE TENANTS SEEN THESE MATERIALS? HOW WERE THEY DISTRIBUTED? DO THEY FIND THE MATERIALS TO BE USEFUL?]**

C. Heat Pump Awareness and Perceptions

C1. Before participating in this heat pump offering, were you familiar with heat pumps?

C2. Prior to participating in this offering, had you ever had a contractor recommend heat pumps?

C3. Before you participated in this offering, were you aware that Consumers Energy offered rebates for heat pumps?

1. **[IF HEARD ABOUT OFFERING]** Where did you hear about the heat pump offering?
2. **[IF HEARD ABOUT OFFERING]** What were your immediate perceptions of the offering?

C4. Other than **[NAME OF PROPERTY IN THE HEAT PUMP OFFERING]**, do any of your properties currently have heat pumps installed for heating and cooling?

1. **[IF HAS HEAT PUMPS INSTALLED]** How many (if any) of the properties you own/manage use heat pumps? **[PROBE TO SEE IF THEY ARE IN MICHIGAN]**
2. For those properties, do residents typically retain secondary or supplemental heating equipment after the heat pump is installed? Please describe.

D. Motivators and Barriers

D1. What were the most important factors in your decision to participate in the heat pump offering? **[DO NOT READ OR PROMPT; SELECT ANY THAT ARE MENTIONED]**

1. Lower tenant utility costs
2. Lower owner utility costs
3. Improve the property appearance
4. Improve tenant comfort
5. Increase the property value
6. Replace old or broken equipment
7. Take advantage of low-cost/no-cost improvements
8. Reduce impact on the environment
9. Lower operating and maintenance costs
10. Improve property aesthetics
11. Improve health and safety
12. Satisfaction with previous Consumers Energy program experience
13. Turnkey and easy to participate
14. Other (Please specify)

98. Don't know

D2. Which of these factors was the most important to your decision? **[REPEAT THOSE MENTIONED IN PREVIOUS QUESTION TO ALLOW SELECTION FROM LIST]**

D3. What do you consider to be the primary barriers to adding heat pumps to other properties? **[DO NOT READ OR PROMPT; SELECT ANY THAT ARE MENTIONED]**

1. Overall upfront costs
2. Logistical effort required to deal with installation
3. Finding the right contractor
4. Getting management approval
5. Tenant disruption
6. Tenants' ability to use the equipment to reduce energy consumption
7. Other (Please specify)

98. Don't know

D4. Which of these factors is the most significant barrier to your decision? **[REPEAT THOSE MENTIONED IN PREVIOUS QUESTION TO ALLOW SELECTION FROM LIST]**

E. Savings and Benefits of Participation

E1. Do you or your tenants pay the electric utility bills?

E2. **[IF TENANTS PAY]** Have your tenants provided feedback about their bills since installation of the heat pumps? If so, please describe what this feedback has entailed.

E3. **[IF PROPERTY OWNER/MANAGER PAYS UTILITY BILLS]** Have you noticed any change in your utility bills since installation of the heat pumps? If so, please describe the change. **[PROBE: HAVE THERE BEEN ANY DIFFERENCES IN UTILITY BILL CHANGES BETWEEN WINTER HEATING AND SUMMER COOLING?]**

E4. In addition to energy savings, are there any other benefits that your property, your tenants, or property management have experienced from installing the heat pumps? **[DO NOT READ OR PROMPT; SELECT ANY THAT ARE MENTIONED]**

1. Lower maintenance costs
2. Improved operations
3. Increased property value
4. Decreased vacancy rates
5. Increased rental income
6. Increased net operating income
7. Increased tenant comfort
8. Decreased late or nonpayment of rent
9. Decreased tenant complaints
10. Improved property aesthetics
11. Health and safety improvements
12. Other (Please specify)
13. Too soon to tell
14. No other benefits

98. Don't know

E5. **[ASK IF E3=YES AND E4≠13, 14, OR 98]** Considering that the heat pump offering provided both energy savings and some other benefits to your property, please indicate which was the <u>most important</u> benefit:

1. The energy savings
2. The non-energy benefits (previously identified)
3. The energy savings benefits are equal to the non-energy benefits

98. Don't know

F. Outreach and Marketing

F1. What, in your opinion, could be done to increase the adoption of heat pumps in the multifamily market?

F2. What are the most effective ways to let other multifamily property owners and managers know about the benefits of heat pumps?

F3. What information would be helpful for other property managers and owners to become interested in heat pumps?

CADMUS

G. Opinion of Heat Pump Offering and Consumers Energy

G1. Taking everything into consideration, how would you rate your overall experience with the multifamily heat pump offering, where 1 means *unacceptable* and 10 means *outstanding*?

Unacceptable 1	2	3	4	Average 5	6	7	8	9	Outstanding 10	Don't know
○	○	○	○	○	○	○	○	○	○	○

G2. Based on your experiences with the heat pump offering, how likely would you be to recommend the offering to a business colleague, where 1 means *extremely unlikely* and 10 means *extremely likely*?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

G3. Based on your experiences with the heat pump offering, how likely would you be to recommend Consumers Energy to a business colleague if you had a choice in energy providers, where 1 means *extremely unlikely* and 10 means *extremely likely*?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

G4. Based on your experience with the heat pump offering, how likely would you be to make similar improvements to some or all the properties you manage, where 1 means *extremely unlikely* and 10 means *extremely likely*?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

H. Wrap Up

H1. In what ways can Consumers Energy programs better help you manage your multifamily properties' energy use?

H2. Our research also includes a tenant survey to capture their experience and usage with the heat pumps, but we do not have tenant contact information to recruit them for this effort. Would you be interested in **[OPTION A]** securely sharing tenant emails with us so they can receive an email link to complete an online survey or **[OPTION B]** would you be willing to forward an email invitation to your tenants to complete the online survey? Tenants will receive a $15 gift card for their time. [**ENTER WILLINGNESS RESPONSE OPTION AND BE SURE TO REQUEST THE PMO EMAIL ADDRESS TO ENSURE EITHER OPTION CAN BE SHARED**]

Those are all the questions we have. Thank you very much for taking the time to assist us with this evaluation. Your contribution is a very important part of the process. We are planning to send you your choice of a $50 Amazon or Meijer card (if you choose Meijer, we will need your mailing address, as there is no e-card option). Please let us know your choice of card **[ENTER CARD CHOICE AND REQUEST EMAIL ADDRESS IF AMAZON OR MAILING ADDRESS IF MEIJER]**.

Look for your gift card in the mail in the next three weeks. If you have any questions about this survey or about your gift card, please call **[APEX STAFF]** at **[303-590-9888 Ext XXX]**. Thank you for your time.

CADMUS

Appendix E. Consumers Energy Heat Pump Multifamily Tenant Survey Guide

Objectives	Research Questions	Question Number
Document participant awareness of heat pump	Are tenants aware of what a heat pump is? Were tenants aware of a heat pump installed for their apartment? Are tenants who were aware of the heat pump also aware that Consumers Energy funded it?	Section B
Document participant installation experience	How did the heat pump offering help Consumers Energy to manage the tenant installation experience? Are there opportunities to improve the installation experience?	D1–C3
Assess participant perceptions of heat pump impact on comfort levels and electricity bills	What perceptions do tenants have of heating and cooling comfort levels? What are the perceived energy benefits of heat pumps? What non-energy benefits did the offering generate (such as reduced bill impacts, enhanced comfort levels, and improved operational issues)?	C4–C11, D2–D4
Document participant usage behavior and experience	How are tenants using and operating the heat pumps? Are tenants continuing to use their baseboard heating?	C12–C18
Assess participant satisfaction with the offering and with Consumers Energy	How satisfied are tenants with the heat pumps offering? How satisfied are tenants with Consumers Energy?	E1–G3, A1, A2

Survey Overview: The Evaluation team administered a web-based survey with multifamily tenants who received a new heat pump. Then the team sent an email with a link to the survey to participants who could be matched to participating multifamily buildings and had an email address, followed by reminder emails to encourage households to complete the survey within the desired timeframe. In addition, the Evaluation team offered participants a $15 Meijer or Amazon.com gift card for completing the survey.

Target Audience: Census of individual tenant dwellings that could be matched to the multifamily building and had an email address. The Evaluation team had 75 emails associated with the multifamily properties by linking an income-qualified survey contact database with the Income Qualified Multifamily incentive properties. Assuming a 10% response rate, we hoped to receive approximately eight completed surveys.

CADMUS

A. Current Company Metrics

First, we'd like to ask some questions about your opinions toward Consumers Energy.

Consumers Energy Count on Us®

A1. How likely would you be to recommend Consumers Energy to a friend or family member if you had a choice in energy providers?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
O	O	O	O	O	O	O	O	O	O	O	O

A2. Please describe in detail why you gave that rating. _____

B. Awareness

B1. Are you familiar with what a heat pump is?

1. Yes, I am familiar
2. No, I do not know what a heat pump is

[IF B1=2, PROVIDE EXPLANATION ABOUT HEAT PUMPS: HEAT PUMPS ARE EQUIPMENT THAT PROVIDES BOTH HEATING AND COOLING FOR HOMES.]

B2. Our records indicate that the apartment you currently occupy received a new heat pump. Are you aware of this?

1. Yes
2. No

B3. **[If B2=1]** Were you aware that Consumers Energy funded this project and made the heat pump technology available in your home?

1. Yes, I was aware of Consumers Energy involvement
2. No, I was unaware of Consumers Energy involvement

98. Don't know

CADMUS

C. Installation and Usage Experience

Next, we would like to know about your experience with the heat pump.

[SHOW QUESTIONS D1 TO C3 IF COMPLETE DATE IS NOT EMPTY]

C1. Our records indicate that the heat pump was installed in your apartment around **[COMPLETE DATE]**. Were you present during the installation of the heat pump?

1. Yes, I was present during installation
2. No, I was not present during installation

C2. Using a rating scale from 1 to 10, where 1 is *unacceptable* and 10 is *outstanding*, how would you rate each of the following installation experiences with the heat pump offering?

Question	Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
Scheduling a time for installation	○	○	○	○	○	○	○	○	○	○	○
Staying informed about the installation	○	○	○	○	○	○	○	○	○	○	○
[IF C1=1] Overall installation time	○	○	○	○	○	○	○	○	○	○	○
[IF C1=1] The professionalism of the installation technician	○	○	○	○	○	○	○	○	○	○	○
Education and instructions provided about heat pump usage	○	○	○	○	○	○	○	○	○	○	○
Follow-up from the installation technician or Consumers Energy	○	○	○	○	○	○	○	○	○	○	○

C3. **[IF ANY QUESTION IN C2≥6]** If there was something unsatisfactory about the heat pump installation, please describe in detail why you gave that rating.

_____

C4. Approximately how long have you lived in your current apartment?

1. Less than six months
2. Between six months and one year
3. Over one year

C5. Were you living in your apartment last winter, before the heat pump was installed?

1. Yes
2. No

C6. **[IF C5=1]** How would you rate the heating comfort level provided by the heat pump during winter months?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
○	○	○	○	○	○	○	○	○	○	○

C7. **[IF C6<7]** What concerns do you have about the heat pump's ability to heat to your comfort level? _____

C8. Were you living in your apartment last summer, before the heat pump was installed?

1. Yes
2. No

C9. **[IF C8=1]** How would you rate the cooling comfort level provided by the heat pump during summer months?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
○	○	○	○	○	○	○	○	○	○	○

C10. **[IF C9<7]** What concerns do you have about the heat pump's ability to cool to your comfort level? _____

C11. In general, how did the heat pump affect your home comfort? (Select all that apply)

1. My home is **just as comfortable** as it was previously
2. My home is **more comfortable** than it usually was
3. My home is uncomfortably warm
4. My home is uncomfortably cold
5. My home is **too humid**
6. My home is **too dry**
7. My home was more evenly heated and/or cooled prior to the installation
8. Something else (please describe)

C12. Our records indicate that the existing baseboard heating equipment was left in all apartments where heat pumps were installed.
Which of the following best describes how you heated your apartment last winter?
[RANDOMIZE 1-3]

1. Mostly used baseboard heating
2. Relied evenly on the heat pump and baseboard heating
3. Mostly used the new heat pump

98. Don't know

C13. Your baseboard heating should have a thermostat that controls your home's heating.
What type of thermostat do you have in your home?

1. **Non-programmable** thermostat (set temperature manually and it did not change automatically)
2. **Programmable** thermostat with **set-backs programmed** (thermostat set to automatically change temperature at specific times)
3. **Programmable** thermostat—**not programmed** (thermostat has programming capability, but these were not used.)
4. **Basic networked or Wi-Fi–enabled** thermostat (had remote control, but not occupancy sensing or learning features)
5. **Smart learning** thermostat that includes advanced features such as occupancy sensing and schedule learning (examples include Nest, Ecobee, Honeywell Lyric, and Emerson Sensi)

98. Don't know

C14. Who in your household tends to monitor and adjust your thermostat associated with your baseboard heating?

1. I mostly monitor and adjust my home baseboard thermostat
2. Everyone in my household monitors and adjusts my home baseboard thermostat
3. Members of my household (other than me) typically monitor and adjust my home baseboard thermostat

C15. How did your household **most frequently** manage your baseboard thermostat to control the temperature in your home this summer?
1. Keep it at a constant temperature
2. Manually adjust the temperature as needed
3. Create customized/programmed settings to automatically change temperatures at different times of the day
4. Allow the smart thermostat to manage the temperature by learning my preferences and/or detecting when home or away
5. Other (please describe)
98. Don't know

C16. Your heat pump offers the ability to use heating and cooling schedules. Did the installation technician set up your heat pump on a heating and cooling schedule?
1. Yes, the installer set up a heating and cooling schedule
2. No, the installer did not set up a heating and cooling schedule
98. Don't know

C17. **[IF C16=1]** Are you still using this heating and cooling schedule?
1. Yes, I have kept the heating and cooling schedule
2. No, I (or someone in my household) turned off the heating and cooling schedule
3. No, I (or someone in my household) changed the heating and cooling schedule to my own
98. Don't know

C18. Have you been provided with instructions on how to set up and control your heating and cooling schedule on your heat pump?
1. Yes, I received instructions
2. No, I did not receive instructions
98. Don't know

D. Savings and Benefits of Participation

D1. How would you describe how your electric utility use is billed?
1. I receive a monthly electric utility bill directly from the utility for my usage
2. My landlord receives an electric utility bill for the whole building's usage
3. The electricity use for my unit is billed some other way (please describe)
4. I'm not sure how the electric utility use is billed

D2. **[IF E1=1]** Have you seen a lower-than-expected energy bill?
1. Yes
2. No
3. Too soon to tell
98. Don't know

D3. In addition to energy savings, if any, are there other benefits that you have experienced or observed from the installation of heat pumps? (Select all that apply) **[RANDOMIZE 1–8]**

1. Increased comfort
2. Lower utility bills
3. Decreased complaints about my apartment temperature
4. Improved air quality
5. Improved appearance of my apartment
6. Improved heating and cooling distribution (across sections of my home)
7. Fewer illnesses for household members
8. Improved ability to manage heating/cooling on a schedule
9. Other (Please specify)
10. Too soon to tell [EXCLUSIVE OF OTHER RESPONSES]
11. No other benefits [EXCLUSIVE OF OTHER RESPONSES]

98. Don't know [EXCLUSIVE OF OTHER RESPONSES]

D4. **[ASK IF D2=1 AND D10≠10, 11, OR 98]** Considering that the heat pump offering provided both saved energy and some additional benefits to your apartment, please indicate which was most important to you:

1. The energy savings
2. The other benefits previously identified
3. The energy savings are equal to the other benefits

98. Don't know

E. Opinion of Heat Pump Offering and Consumers Energy

E1. Taking everything into consideration, how would you rate your overall experience with the heat pump?

Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know
○	○	○	○	○	○	○	○	○	○	○

E2. Based on your experiences with the heat pump, how likely would you be to recommend a heat pump to a friend?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already Did Recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

E3. Do you have any recommendations for ways Consumers Energy can further support you in saving energy?
   1. Please describe_____

F. Closing

F1. On occasion, managers of the Consumers Energy programs may want to contact a customer to learn more about their participation experience. **Please check here if you prefer not to be contacted by a program manager.**
   1. Do not contact me

F2. To thank you for your time spent completing this survey, we would like to send you a $15 gift card to either Meijer or Amazon.com. Please choose which gift card you would like to receive.
   1. $15 Meijer gift card
   2. $15 Amazon.com gift card
   3. Neither – I do not wish to receive a gift card

F3. **[ASK IF F2=1 OR 2]** Please provide your name, address, and email to receive your gift card. This information will only be used to mail your gift card.
   1. Name:_____
   2. Address:_____
   3. Address 2:_____
   4. City:_____
   5. State:_____
   6. Zip:_____
   7. Email**:** _____

Please click Next to submit the survey.

Those are all the questions we have at this time. Thank you for your participation in the Consumers Energy heat pump offer.

For more information on energy efficiency, here's where to find it:

- **Want Online Information about Our Other Energy-Efficiency Rebates and Programs?** For details of additional ways Consumers Energy may be able to help you make your home more energy efficient and help you manage your monthly energy bills, please visit us online at ConsumersEnergy.com/myhome.
- **Want to Speak to an Energy-Efficiency Advisor by Phone?** To talk to someone about additional rebates and programs, please contact one of our Energy Advisors at (888) 652-1237.

Appendix F. Consumers Energy Heat Pump Commercial Interview Guide

Cold-Climate Heat Pump Participant Interview Research Objectives and Questions

Objectives	Research Questions	Interview Questions
Explore key factors in customer decision-making regarding heat pump installations	Were customers aware of heat pumps prior to the pilot outreach?	C1, C1a, C1b, C1c
	What were customers' perceptions of heat pumps prior to installation? What barriers did customers face when considering the installation of heat pumps?	C3
	What motivated customers to install heat pumps?	C5, C5a, C5b
	What technology would customers have installed without the initiative intervention and why?	C4, C4a
Explore customer experiences during the heat pump installation process	How did participants find their contractor who installed the equipment? How did participants perceive their contractors knowledge of heat pump technology and installation methods? How did participants perceive the length of time to purchase and install the heat pump and how long did that process take?	D1, D2, D4, D4a, D5
	What type of equipment did customers use prior to the heat pump? Did participants need to install new duct work, a new thermostat, and/or back-up systems for their heat pump?	D6, D7, D8, D9, D10
	Were participants satisfied with their contractors (including their interactions with their contractors and the contractors' performance), the installation process, and the timeline? Why or why not? Would they use the contractor again?	G1a, G1b, G1d, D3
Explore customer experiences using their heat pump	Does the heat pump provide the level of heating required for comfort and meeting customer needs?	E2, E2a
	Does the heat pump provide the level of cooling required for comfort and meeting customer needs?	E3, E3a
	Can customers operate the heat pump easily, including the remote controls? Do they need to change their habits in any way?	E1, E4, E4a, E5, E5a, E5b, E6
	How does the heat pump compare to prior equipment with regards to air quality?	E7, E7a
	How does the heat pump compare to prior equipment with regard to noise?	E8, E8a
	Are participants satisfied with their heat pump? Why or why not?	G1c
Explore customer experiences with the initiative offering	How did participants learn of the initiative opportunity?	C2
	Did participants interact with program staff? If so, what were their experiences?	F1, F1a, F1b
	Were participants satisfied with the pilot offering?	G1e
Identify opportunities to best support heat pump technology moving forward	Which aspects of the initiative offering were most helpful to customers (such as the staff support versus the financial incentive)?	F4
	What additional support, if any, did participants need to pursue the installation and use of their heat pump?	F2, F2a, F3, F3a, D4b

Survey Overview. The Evaluation team attempted to interview the full population of participating customers, with a goal to complete at least five interviews. The team included a $75 incentive to increase the likelihood of response. The Evaluation team sent advance emails to all respondents with available email addresses and followed up with phone calls as needed to schedule interviews. This email explained the research and provided a Consumers Energy and Evaluation team contact person if the respondent had additional questions or wanted to schedule an interview. For phone recruitment, the

team left a voicemail or receptionist message on the first attempt whenever possible, then used discretion to determine any additional messages left on subsequent attempts (with a maximum of five attempts to each contact).

A. Introduction

A1. First, can you tell about the work you do at **[BUSINESS NAME]**?

A2. And what is your role at the business? **[PROBE FOR ROLE AND RESPONSIBILITIES]**

B. Consumers Energy

Next, we'd like to ask you a few questions about your opinions toward Consumers Energy.

B1. How likely is it that you would recommend Consumers Energy to a friend or colleague if you had a choice in energy providers using a scale from 1 to 10, where 1 means *extremely unlikely* and 10 means *extremely likely*?

Extremely unlikely 1	2	3	4	5	6	7	8	9	Extremely likely 10	Already did recommend	Don't know
○	○	○	○	○	○	○	○	○	○	○	○

B2. Please describe why you gave that rating.

B3. To what extent do you agree that Consumers Energy made it easy to participate in the Cold-Climate Heat Pump Initiatives, using a scale from 1 to 5, where 1 means *strongly disagree* and 5 means *strongly agree*?

Strongly disagree 1	2	3	4	Strongly agree 5
○	○	○	○	○

C. Decision-Making

Next, I'd like to ask some questions about your decision to install a heat pump.

C1. Prior to Consumers Energy contacting you about the heat pump offering, how familiar were you with heat pump technology to heat and cool your facility?

1. **[IF AWARE, PROBE]** What were your perceptions of heat pumps?
2. **[IF AWARE, PROBE]** Had you heard anything about their performance in colder climates?
3. **[IF KNOW ABOUT HEAT PUMP PERFORMANCE IN COLD CLIMATES]** Where did you hear about it?
4. **[IF AWARE, PROBE]** Had you heard anything about their performance in colder climates?

C2. How did you first learn of the opportunity to receive a heat pump through Consumers Energy?

C3. What key concerns or considerations did you have when deciding whether or not to install the heat pump?

C4. What motivated you to agree to install the heat pump?
1. Were there any other factors? **[PROBE FOR COST, ENERGY SAVINGS, ENERGY-EFFICIENCY, REBATE FROM CONSUMERS ENERGY]**

C5. Did you have plans to install new heating or cooling equipment if Consumers Energy hadn't reached out to you?
1. **[IF WOULD HAVE INSTALLED NEW HVAC EQUIPMENT]** When would you have installed this new equipment?
2. What steps would you have taken to decide what equipment to purchase?

D. Experience with Contractor Selection and Installation Process

The next set of questions are about your experiences finding a contractor and installing of your new heat pump.

D1. So, once you decided to participate in Consumers Energy's Cold-Climate Heat Pump offering, can you talk me through the steps you took to find and select a contractor to perform the work?

D2. Did you have any difficulties finding a contractor to perform the work?

D3. How knowledgeable were the contractors you worked with about heat pumps? What about the installation process? **[PROBE IF ANY DID NOT SEEM TO BE KNOWLEDGEABLE ABOUT THE EQUIPMENT, WHERE THEY WERE LACKING KNOWLEDGE]**

D4. Once you found a contractor, how long did the project take from start to finish (purchasing to installing)? Did this timeline meet your expectations?
1. **[IF TIME EXPECTATIONS NOT MET]** What were your expectations?
2. **[IF TIME EXPECTATIONS NOT MET]** Is there anything that could have been done differently? **[PROBE IF ANY PART OF THE PROCESS TOOK LONGER THAN EXPECTED]**

D5. If you had to do it over again, would you work with the same contractor?

D6. Prior to the installation, what type of heating equipment did you use? Did you use electric or natural gas or another type of fuel to heat the property?

D7. What type of cooling equipment did you use?

D8. Did your contractor need to install new duct work, a new thermostat, or other infrastructure as part of the heat pump installation?

D9. What did your contractor do with the old heating system? **[PROBE IF REMOVED, KEPT IN PLACE AS BACKUP, CAPPED]**

D10. Did you need to install a new back-up system along with the heat pump? **[PROBE FOR HEATING OR COOLING SYSTEMS]**

E. Experience Using the Heat Pump

Next, I'd like to ask some questions about your experiences using the heat pump itself.

E1. What have been your experiences with operating the equipment to date?

E2. Have you had a chance to use the heating function on the heat pump that was installed at your facility?
   1. **[IF USED HEATING]** What time of year did you use the heating function? Did you have any issues with the heat pump providing sufficient heat for your comfort and meeting your needs? **[PROBE FOR IF THEY EVER HAD ISSUES PROVIDING HEAT]**

E3. Have you used the cooling function?
   1. **[IF USED COOLING]** Did you have any issues with the heat pump providing sufficient cooling for comfort and meeting your needs?

E4. Does the heat pump require any new operating procedures that you needed to learn how to use?
   1. How did that go?

E5. Does the equipment rely on a remote control or app?
   1. Do you use that feature?
   2. How has that gone?

E6. Have you had to change your heating/cooling habits in any way to accommodate the new technology?

E7. Have you noticed any changes in air quality since the heat pump was installed? **[PROBE: DECREASED AIR PARTICLES, NOXIOUS GASES, DEBRIS]**
   1. **[IF YES]** How so?

E8. How does the sound of the new equipment compare to your old heating/cooling equipment?
   1. **[IF SOUND WORSE]** What have you done to deal with the noise, if anything?

F. Experience with Pilot Offering

Next, I have a few questions about your experiences with Consumers Energy in relation to this pilot and then we'll be almost done.

F1. Did you interact with Consumers Energy program staff at any point in the process?
   1. **[IF YES]** What did you discuss?
   2. Did you get your questions answered?

F2. What additional support, if any, did you need *when considering to purchase and install* your heat pump?
   1. Who did you talk to? What questions did you have?

F3. Did you require any additional support—other than what you received from Consumers Energy—during the *installation process*?
   1. What about when using the equipment?

F4. Thinking about all the aspects of the initiative, from the support you received in picking equipment or a contractor to the financial rebate for the project, what aspect was most helpful in your decision to pursue the heat pump installation?

G. Satisfaction

I'd like to wrap up the conversation by asking you to rate your satisfaction on a few different factors.

G1. Feel free to expand on any answers you provide. Each of these items will be on a 1 to 10 scale, where 1 means *unacceptable* and 10 means *outstanding*.

Question	Unacceptable 1	2	3	4	5	6	7	8	9	Outstanding 10	Don't know / NA
The installation your contractor performed	○	○	○	○	○	○	○	○	○	○	○
The time it took to receive and install your equipment	○	○	○	○	○	○	○	○	○	○	○
The performance of the heat pump equipment	○	○	○	○	○	○	○	○	○	○	○
The interactions you had with your contractor	○	○	○	○	○	○	○	○	○	○	○
The overall Consumers Energy offering	○	○	○	○	○	○	○	○	○	○	○

CADMUS

H. Closing

As we wrap up, I want to provide an opportunity for you to share anything I might have missed with my questions.

H1. Do you have any other comments or information you think might be useful for me to know given what we have talked about today?

H2. These are all the questions I have for you today. It is likely that one of our colleagues will be following up with you in a few months to better understand the energy use of your new cold-climate heat pumps during the winter months, so look out for that email or call. As a thank you for your input, we'd like to send you a $75 gift card redeemable at many businesses, including Amazon, Target, and Kroger. This gift card is called a Tango card and would be sent to your email address within the next five to 10 business days. Alternatively, we can donate the $75 to your local United Way. Which would you prefer?

H3. **[IF TANGO]** Could you please provide your preferred email address to receive the Tango virtual gift card? **[REPEAT BACK EMAIL ADDRESS]**
You should expect to receive your virtual gift card within the next five to 10 business days. The gift card will be emailed directly from **Tango,** with a reference to "Thank you for your participation!" If you have any questions, or have not received your gift card by then, please contact me at **[contact information]**.

H4. [IF UNITED WAY] In whose name should we make the donation to United Way? [INCLUDE FIRST AND LAST NAMES, COMPANY NAME, OR ANONYMOUS]

And what zip code should we use to find your local United Way?

On behalf of Consumers Energy, I want to thank you for taking time to provide input, and have a great day. **[END CALL]**

CADMUS

Appendix G. Consumers Energy Heat Pump Contractor Interview Guide

Introduction and Purpose

Thank you for taking the time to talk with us today. This interview is a discussion about air source cold climate heat pumps, your businesses experience with the technology, and to assess the current status of the technology in the market. The intended outcome of this discussion is to document the perception, concerns, opportunities, critical decision points, and key outcomes involved with heat pump sales and installations. Consumers Energy can use this documentation to guide future decision making around their energy efficiency programs. We are offering a $75 gift card that can be redeemed at your choice of Amazon or Meijer for those that complete the 30-45 minute interview. We have four main objectives for this interview:

- Identify current levels of awareness and perceptions of heat pump technologies.
- Identify the main barriers to installing heat pumps in Michigan and if the Michigan market is ready for widespread adoption of heat pump technology.
- Identify any marketing or outreach best practices
- Document awareness of available heat pump incentive offerings

We expect this interview to take around 30 minutes.

A. General Introduction

A1. To begin, tell me about your business.
   1. What types of customers do you typically serve? [Standard residential? Income qualified? Multi-family? Commercial? Something else?]
   2. How many projects do you typically complete in a given year?
   3. How many employees does your company have?

A2. What type of equipment do you typically install? [Furnaces? Boilers? Heat pumps? Something else?]

A3. Do you have any experience participating in utility energy efficiency programs?
   1. Which utilities? Which programs? How often?

B. Heat Pump Awareness and Perceptions

B1. Does your company sell and install heat pumps?

1. **[If installs heat pumps]** How many (if any) heat pump sales or installations have you/your company had in the past year (2020)?
2. For those installations, do residents typically retain secondary or supplemental heating equipment after the heat pump is installed? Please describe.
3. What heat pump brands do you carry and install?
   Have you received any manufacturer-specific certifications for installing those brands?
4. How does the average warranty of a CCHP compare to gas furnaces or boilers?
5. **[If does not install heat pumps]** Why don't you install heat pumps?

B2. Do you promote CCHPs to your customers?

1. Are there specific applications or customer types that make good candidates for heat pumps? (i.e. retrofit vs. new construction)
2. Which ones?
3. Why?
4. Are small businesses good candidates for heat pumps?
   Are the barriers to entry different than the residential homeowner?

B3. Generally, what are your perceptions of CCHPs?

1. Do you think that CCHPs are a viable option for widespread adoption in Michigan?
2. Do you think that CCHPs are capable of generating energy savings for end users?
3. What has led to those perceptions of the equipment?
4. What do you think is the value proposition for you to want to install heat pumps? Why would you not want to?
5. Do you know other contractors who install CCHPs? What are their perceptions of the technology?

B4. What are customer perceptions of heat pumps?

1. Do they typically have any awareness of the technology?
2. What do you think is the value proposition for customers to install a heat pump? What are their motivations? If needed: Why would they not want to?
3. Do customers ever request to have the equipment installed without being prompted by your company? How do you respond to that request?
4. Is customer interest in heat pumps increasing, decreasing, or staying about the same? What would you say is causing that change?

B5. To what extent does a negative experience with older heat pump technologies affect your opinion about heat pumps? What about customers experiences?

CADMUS

C. Market Barriers and Regulatory Readiness

C1. **[If installs heat pumps]** How do procedures for a heat pump installation compare to installing other HVAC equipment in terms of:
1. Time required (actual installation time).
2. Sales process/discussions with customers.
3. Revenue/Profit Margin.
4. Equipment availability.
5. What factors can cause variations in these procedures? (e.g. conversion vs. replacing similar equipment).

C2. What would you say are the main barriers or challenges preventing more widespread heat pump adoption in Michigan? [Probe for: customer awareness, contractor perceptions, equipment availability, codes and standards, energy prices, finding good candidates, etc.]

C3. If demand for heat pumps increases, how well do you think the supply chain is prepared to meet that demand (increasing production) for cold climate heat pumps? Why?
1. Do you have any concerns about the availability or delivery timing of heat pump equipment for current or future projects? Why or why not?

D. Outreach and Marketing

D1. What can Consumers Energy do to help drive adoption of heat pumps in the market?

D2. Do you think that messaging is needed to educate people that CCHPs, or heat pumps in general, have improved?
1. **[IF YES]** What would effective messaging look like?

D3. **[If Promotes heat pumps]** When you have a good candidate for a heat pump, what information is most convincing for the customer to install a heat pump?

E. Wrap Up

E1. Before we wrap up, is there anything else you'd like us to know?

Those are all the questions we have for you. Thank you very much for taking the time to assist us with this evaluation. Your contribution is a very important part of the process. Do you mind if we follow-up with you by phone or e-mail later, if additional questions arise?

E2. To thank you for your time spent completing this survey, we would like to send you a $75 gift card to either Meijer or Amazon.com. Please choose which gift card you would like to receive.
1. $75 Meijer gift card
2. $75 Amazon.com gift card
3. Neither – I do not wish to receive a gift card

CADMUS

E3. Please provide your name, address, and email to receive your gift card. This information will only be used to mail your gift card.

1. Name:_____
2. Address:_____
3. Address 2:_____
4. City:_____
5. State:_____
6. Zip:_____
7. Email**:** _____

You should receive your gift card within four weeks. If you have not received it by then, please contact (contact person at Cadmus).

Appendix H. Consumers Energy Heat Pump Manufacturer and Distributor Interview Guide

Research Objectives and Questions

Research Objectives	Research Questions	Interview Questions
Confirm/document the supply chain for CCHPs in Michigan	Do CCHPs follow the typical supply chain structure (Manufacturer -> Distributor -> Contractor -> Customer)?	EE1, EE2
	Does the supply chain vary for small commercial, multifamily, and residential end uses?	EE1
Identify the barriers leading to extended timelines for CCHP installation	How long does it typically take from manufacturing to distribution? Distribution to contractors?	FF1
	What caused delays in the timeline in 2020? Have there been any changes to this timeline due to COVID-19? Were delays different across states? Did demand for CCHP in Michigan differ in 2020 compared to 2019?	FF1, FF2, GG2
	Are any delays expected to improve in 2021?	FF1
Identify sources of differences in CCHP installation costs across states	Are wholesale costs in Michigan comparable to other states?	FF3
	What factors drive pricing of CCHPs?	FF3
Explore the cause of low participation by trade allies	What have manufacturers and distributors done to promote heat pump technology?	GG5, GG6
	What feedback have contractors (distributors) offered to distributors (manufacturers) on perceptions of CCHP?	GG3, GG4
Identify any additional barriers and challenges delaying widespread adoption of CCHPs in Michigan, like training or education	What are the primary barriers or challenges faced by manufacturers / distributors in selling and distributing CCHP?	GG1, G1
Identify ways in which Consumers Energy can influence market adoption	How can utilities best support the adoption of CCHPs? Where is the correct place to offer an incentive (downstream, midstream, or upstream)?	II1
	Are there successful market influences in other states that could be promoted in Michigan?	HH1
	Are there technology advancements that Consumers Energy should be aware of?	HH2

A. Firmographics

First, I have just a couple questions about your organization and your role. Please note that I will keep your individual responses anonymous.

A1. What is your role in the company?

A2. What areas of the country does your company primarily serve?

A3. **[DISTRIBUTORS]** Do you serve as a distributor of heat pumps in states other than Michigan? **[PROBE FOR DETAIL]**

A4. **[MANUFACTURERS]** Do you work with particular states/regions or nationwide? **[PROBE FOR DETAIL]**

B. Supply Chain

Now I have some questions about the supply chain for the cold-climate air-source heat pump market. If possible, I would like you to focus your responses on the market in the state of Michigan.

B1. How does heat pump equipment typically get from the manufacturer to the end-use customer?
1. What are the key roles in the cold-climate heat pump market from production to installation (such as manufacturers, distributors, contractors, and electricians)?
2. Does the supply chain for cold-climate heat pumps differ from traditional air-source heat pumps? What about other types of mechanical equipment (such as furnaces, boilers, or water heaters)? If so, how?
3. Does the supply chain vary depending on the type of building where the unit will be installed (single family, multifamily, or small commercial building)?

B2. Are there particular distributors, manufacturers, or contractors you work with for cold-climate heat pumps in Michigan? **[PROBE FOR DETAIL]**

C. Timeline/Costs

Next, we would like to ask you some questions specifically surrounding production and distribution timelines and costs.

C1. On average, what would you say is the length of time it normally takes for a cold-climate heat pump to reach the distributor or contractor after an order is placed?
Does the timeframe in Michigan differ from other states?
1. **[MANUFACTURERS]** When fulfilling orders for cold-climate heat pumps, what specific manufacturing challenges, if any, have you experienced in the Michigan market? **[PROBE FOR DETAIL]**
2. How does this compare to other states?
3. Did production times change from 2019 to 2020? If so, how? What do you attribute this to?
4. What do you think production times will look like in 2021?
5. **[DISTRIBUTORS]** Have you experienced any issues with the availability of cold-climate heat pumps in Michigan? **[PROBE FOR DETAIL]**
6. How does this compare to other states?
7. Did availability change from 2019 to 2020? If so, how? What do you attribute this to?
8. What do you think availability will look like in 2021?
9. Does the timeline for cold-climate heat pumps vary by season? If so, how?

C2. **[DISTRIBUTOR]** Do you typically stock cold-climate heat pumps or do you place orders after a purchase is made?
1. How many units do you typically have on-hand? What types? Are NEEP specifications considered? What led to your decision to stock these units?
2. **[IF NOT]** What prevents you from stocking cold-climate heat pumps?

C3. Compared to other states, are cold-climate heat pumps in Michigan competitively priced?

1. Have costs been stable over time?
   [PROBE] Have costs differed from 2019 to 2020?
   [PROBE] Do you think that change is temporary?
2. **[MANUFACTURERS]** Has there been much variation in cost of parts and labor in the manufacturing of the cold-climate heat pumps?
3. **[DISTRIBUTORS]** Has there been much variation in cost based on availability of cold-climate heat pumps?

D. Demand/Adoption

I would now like to spend a few minutes talking about overall interest for cold-climate heat pumps in the market.

D1. Compared to other states, how much demand is there for cold-climate heat pumps in Michigan?

1. What do you see as the primary barriers or challenges that are restricting widespread adoption of heat pump technology in Michigan?
2. How do warranties for cold-climate heat pumps compare to warranties for other technologies (such as natural gas furnaces)?

D2. In 2020, did demand for cold-climate heat pumps in Michigan differ from 2019?

1. **[IF YES]** What do you think caused that change?
2. Do you think the change was temporary or will it be resolved?
3. Have there been any impacts on demand related to COVID-19, that you are aware of?
   [PROBE FOR DETAIL]

D3. **[MANUFACTURERS]** What feedback have you received from distributors in Michigan about heat pump technology adoption?

1. What about cold-climate heat pumps, specifically?
2. Is this different from other states?

D4. **[DISTRIBUTORS]** What feedback have you received from contractors in Michigan about heat pump technology?

1. Is this different from other states?

D5. Do you know of any promotions or trainings your organization does to increase awareness of cold-climate heat pumps among your customers in Michigan?

1. Does this differ from other states?
2. Is this different from other types of equipment?

D6. Specifically, what has your organization done to promote heat pump technology to distributors/contractors?

1. Have you offered trainings, informational pamphlets, sales/discounts, or something similar?

E. Solutions

In this final section, I'd like to shift gears a little to understand your thoughts on how Consumers Energy and other utilities could provide support to further the adoption of cold-climate heat pump technology.

E1. Is there anything you think utilities could do to improve the adoption of cold-climate heat pump technology in Michigan? **[PROBE FOR DETAIL; SOLUTIONS BEYOND INCREASING INCENTIVES]**
   1. In your opinion, where is the right place to offer an incentive to drive adoption of a newer product such as cold-climate heat pumps (downstream, midstream, or upstream)?
   2. Have you seen models for promoting the adoption of cold-climate heat pumps in other jurisdictions that Consumers Energy should consider?

E2. Are there any recent or upcoming advancements in heat pump technology that Consumers Energy should be aware of?

F. Closing

As we wrap up, I want to provide an opportunity for you to share anything I might have missed with my questions.

F1. Do you have any other comments or information you think might be useful for me to know given what we have talked about today?

F2. These are all the questions I have. As a thank you for your input, we'd like to send you a $75 gift card to Amazon, Target, or Meijer. Amazon and Target gift cards are virtual and would be sent to your email address within the next 5 to 10 business days. Meijer is offered as a physical gift card, which will be mailed to your preferred address. Alternatively, we can donate the $75 to your local United Way. Which would you prefer?
   1. Amazon
   2. Target
   3. Meijer
   4. Please donate to my local United Way

F3. **[IF G2=1 OR 2]** Could you please provide your preferred email address to receive the **[AMAZON OR TARGET]** virtual gift card?

F4. **[IF G2=3]** Let me ask the information we need to mail your gift card to the intended recipient—this could be you personally or anyone else of your choosing:
   1. First name of recipient:
   2. Last name of recipient:
   3. Could you please provide the street address we should use to send the gift card?

You should expect to receive your gift card by no later than **[DATE]**. If you have any questions, or have not received your gift card by **[DATE]**, please contact **[contact information]** and reference the Consumers Energy heat pump interview.

F5. **[IF G2=4]** In whose name should we make the donation to United Way? **[INCLUDE FIRST AND LAST NAMES OR COMPANY NAME]**

On behalf of Consumers Energy, I want to thank you for taking time to provide input, and have a great day. **[TERMINATE]**

Energy burden
Heat pump
Electrification
Energy efficiency
Energy audit
Retrofit

ABSTRACT

Residential heat pumps could reduce greenhouse gas emissions, but increase energy burdens, the proportion of income households spend on utility bills. We analyze utility bills, thermostat settings and energy burdens for a sample of 51 households in Michigan, half below median income. We recruit a contractor to conduct energy assessments of these households and provide them with energy retrofit recommendations, including estimated costs and savings. We find that low-income households choose similar temperature setpoints to higher-income households, but live in less efficient homes. Below-median income households, which today experience a median energy burden of 6 %, would see it rise to 10 % if they shifted to electric heat pumps from natural gas. Weatherization could offset this increase, bringing burdens down to pre-electrification levels. However, median payback is 24 years, making retrofits infeasible for the poorest. Our results are indicative of an energy poverty trap that could hinder an equitable energy transition.

Spotlights

- Converting fossil-fuel based home heating to electric could reduce pollution but make bills less affordable.
- Switching to electric heating results in low-to-moderate income households paying a high percentage of income on energy.
- Retrofitting homes could make electric heating more affordable but it is expensive and therefore infeasible.
- High-cost energy efficiency home retrofits could hinder an equitable energy transition.
- Future work will investigate homeowner attitudes regarding electrifying their homes and barriers to equitable transition.

1. Introduction

In recent years, US state policy (Climate Leadership and Community Protection Act 2020; An Act Creating 2022; Climate Commitment Act 2022)) has signaled a commitment to reducing greenhouse gas emissions by transitioning home heating from fossil fuels to electricity. U.S. federal policy has sought to use subsidies to lower the upfront cost of heat pump adoption (Inflation Reduction Act, H.R. 5376). Electrification has been projected to increase annual utility cost for households in more than half of US states (Vaishnav and Fatimah 2020; Deetjen et al., 2021), with the worst effects in cold climates (Walker et al., 2022). Rising energy costs could have a large impact on households across the income spectrum.

1.1. Literature review

Higher utility bills could increase the economic and physical hardships in households already experiencing energy insecurity. A quarter of American households spend a high proportion (>6 %) of their income on utilities, defined as energy burden (Drehobl et al., 2020). High energy burden is associated with poor health outcomes (Reames, 2016), and households with certain vulnerabilities, such as older adults, choose uncomfortable and sometimes unsafe indoor temperatures to reduce bills (Cong et al., 2022). Lewis et al. center deteriorated housing conditions concentrated in racially segregated neighborhoods in their discussion of energy insecurity, which encompasses financial, behavioral and physical hardships related to home energy use (Lewis et al., 2020).

Households with lower energy burdens are not entirely precluded from the effects of higher ongoing costs associated with heating electrification because these costs are associated with building

characteristics that are prevalent across the US housing stock. Old homes heated by natural gas have been shown to result in the greatest operational costs for heating with a heat pump (Vaishnav and Fatimah, 2020). 64.5 million American homes use natural gas for heating and 57 % of them were built before energy codes were implemented in the US (U.S. Energy Information Administration, 2023). Knowledge of household demographics, housing characteristics, and occupant behavior are essential to understanding the barriers to equitable access to heat pumps and a just distribution of harms and benefits associated with policy that facilitates the clean heating transition.

Current research about residential energy equity includes only one or two of these critical components. Studies that quantify the link between racial disparities in energy use and housing quality (Goldstein et al., 2022; Bednar et al., 2017), and demonstrate that households of color are more likely to have trouble paying their bills (Graff et al., 2021) do not take into account behavior. Studies that evaluate specific retrofit opportunities and quantify their the savings potential by employing national scale modeling do not address behavior impacts associated with those changes (Bradshaw et al., 2014; Wilson et al., 2019). Likewise, studies that examine the economics of heat pump adoption for low income households, whether in observed system performance (Ceglia et al., 2022; Flower et al., 2020; Calver et al., 2022; Pastore et al., 2022; Liu et al., 2018) or simulations (Donaldson and Lord, 2018; Barrella et al., 2020; Liu et al., 2020; Abbasi et al., 2022; Savage et al., 2022) focus on housing and heat pump technology characteristics without an empirical analysis of occupant behavior and preferences for heating and cooling.

Several recent studies examining the energy savings potential of residential retrofits in the European context point to the importance of incorporating household behavior in home energy assessments (Palma et al., 2022; Barrella et al., 2020; Koasidis et al., 2022; Domínguez-Amarillo et al., 2020). The literature addressing the effect of energy consumption behavior on the cost effectiveness of energy retrofits in the US commonly uses economics theory and analysis. Gillingham and Palmer (2014) conducted a literature review of explanations for limited uptake of home energy efficiency including that flawed decision making could reduce the utility of energy efficiency to customers. Three studies followed that examined this question using home energy efficiency project data from the US Department of Energy Weatherization Assistance Program (WAP). Zivin and Novan (2016) measure the treatment effect of retrofits on energy use of 275 households and provide evidence that electricity savings due to WAP are overstated. Allcott and Greenstone (2017) and Fowlie, Greenstone and Wolfram (2018) use large samples of primary empirical data to estimate the benefits of providing energy efficiency services to low-income homes. Though these studies consider behavioral explanations for under performance of projects compared to engineering estimates, they do not provide detail on the housing conditions prior to intervention or the specific work performed. See Table C.7 for a comparison of this paper's contributions to those of the literature.

Other large empirical studies that address impacts of high utility costs on vulnerable households similarly do not provide data on the housing characteristics of the populations they examine (Cong et al., 2022; White and Sintov, 2020), and therefore do not address why these impacts occur. Although Booth and Choudhary (2013) estimate the rebound effect, identify specific upgrade parameters, and focus on public housing in their assessment of uncertainty in retrofit performance (Booth and Choudhary, 2013), they do not address the transition in heating technology. Recent research has signaled the potential for heat pumps to contribute to residential sector clean heating transition where countries push for climate action and fossil fuels remain the predominant fuel source (Fitó et al., 2021; Thomaßen et al., 2021; Besagni et al., 2020).

1.2. Research gaps

There remains a gap in quantifying the impacts of residential heating electrification across income and in examining interventions specific to both housing quality and energy consumption behavior. Previous studies that have taken this form to assess the reasons for disproportionate impacts of energy cost across income (Cong et al., 2022; Jones et al., 2023) only examine it in the context of air conditioning, not heating. To bridge this gap, this study aims to disentangle the sources of inequality embedded in the economic impact of heat pump adoption and assess fixes available for real homes. The present work has three main contributions. First, we provide evidence that energy burden impacts across income are associated with housing quality rather than behavior. Second, we compare economic impact of heating fuel transition across income groups. Third, we test the idea that there is a way to mitigate the utility cost premium for heat pumps.

We conduct a year-long field study of 51 homes in Southeast Michigan, during which we perform a comprehensive energy audit of each home to observe envelope and HVAC system characteristics, including thermal imaging to identify temperature gradients indicative of air leakage and poor insulation, and blower door testing to measure air infiltration rate, as well an examination of the on-label efficiency of all appliances. We gather metered daily gas and hourly electric consumption data over the study period and collect energy assessment contractor recommendations for energy efficiency retrofits for each home. Our approach to examining residential energy equity is novel because we compare results derived from observed data with simulations derived from statistical sampling of large public data sources (Wilson et al., 2022).

Following this introduction, we present the methods, then results, then we will discuss the findings and conclude. We present our findings in five parts. First, we examine the existing conditions of the homes in the study and compare them across income, including key housing characteristics and indoor temperature preferences. Next, we quantify the impact that replacing natural gas heating with heat pumps would have on household energy burden. We then examine the sensitivity of time of use utility rates on the annual energy bill impact of fuel switching. Following that, we quantify the cost savings potential of energy efficiency envelope improvements and compare it to the utility bill impact. Finally, we explore energy efficiency retrofit recommendations provided to participants during home energy audits and assess the feasibility of these improvements to mitigate the ongoing cost impact of heating electrification on the sample.

2. Methods

This study uses observed household energy use and indoor temperature data along with a reduced complexity air source heat pump coefficient-of-performance model to determine energy cost and energy burden impacts of switching to a heat pump. We gather energy retrofit recommendations and estimate upfront costs, energy cost savings, and payback from a contractor who conducted a detailed energy audit for each home. We then quantify annual utility bill impacts for fuel switching and energy retrofits using a building energy model that provides detailed sub-hourly simulations a large sample of archetypal homes that are representative of the study region and compare them to our findings for the sample.[1]

[1] See Data Availability statement for more information on how to access data that can be made available under the Institutional Review Board guidelines for human subjects research. See Supplemental Methods for additional detail on justification for model and calculation assumptions and Supplemental Figure, Tables, and Notes for detail on participant demographics, supporting findings, and literature review.

2.1. Participants

As described below, we recruited 51 participants from Wayne and Washtenaw Counties in Michigan, which encompass the Detroit and Ann Arbor metro areas. We chose Southeast Michigan for three factors that make this study applicable to global contexts including the Midwest, New England, and the Mountain West regions of the US; Northern Europe; and the United Kingdom: cold climate, predominance of natural gas for heating, and older homes.

Participant recruitment included three steps. First, we circulated an expression of interest form through local media, university email lists, and local environmental and energy justice community groups that drew more than 1300 responses. Second, we asked these respondents to complete a demographic survey to assess the presence of key factors associated with energy insecurity: race, income, disability, children, and health vulnerability (Drehobl et al., 2020; Reames, 2016; Hernández, 2016). We received 883 responses to the demographic questionnaire. Third, we identified a random sample stratified using survey answers to ensure representation across four key, binary, classes of vulnerability: has a disability, has at least one child at home, foregoes paying energy bills at least once a year, controls heating or cooling for a vulnerable occupant. These four classes correspond to 16 combinations, and we had respondents who corresponded to only 10 of them.

Next, we identified 418 survey respondents living in single family homes. We then classified the respondents into 10 categories representing the unique combinations of the key categories listed above. We calculated how many households we would need to invite to have an equal number across these categories and randomly selected that many households from each group. Where the quantity of respondents in a category was not great enough to provide an equal weighting, we invited all the respondents in the category. Ultimately, we compiled a list of 90 potential participants to whom we sent invites to join the study. Our recruitment rate was 58 %. Demographic questions and descriptive statistics can be found in Note D.3 and Table C.1. 90 respondents were asked to join the study. Demographic questions and descriptive statistics can be found in Note D.3 and Table C.1.

All households in the sample live in single family homes. 50 of the 51 households are homeowners; 1 is a renter. All homes use natural gas for heating with the exception of 1, which uses propane. The sample includes a diversity of housing vintage (i.e. common building practices) from every decade since 1900: 9 homes were built before 1940, 17 homes were built between 1940 and 1960, 12 built between 1961 and 1980, 6 built between 1981 and 2000, and 7 built after 2000.

The study sample is representative of the populations of the two counties of Southeast Michigan along two key characteristics. (1) Income: the median income (in 2022 dollars) is $57,223 for Wayne County and $84,245 for Washtenaw County (U.S. Census, 2024). The sample includes 11 households reported earning annual income <$25k, 18 earning $25–50k, 9 earning $50–75k and 13 earning >$75k. (2) Race: 54.6 % white, 38.3 % Black, and 7.1 % all other races in Wayne County and 73.9 % white, 12.4 % Black, and 13.7 % all other races in Washtenaw County (U.S. Census, 2024). The sample includes 29 % Black (n = 15), 45 % white (n = 23) and 25 % (n = 13) all other races, including one participant who prefers not to answer.

Households were provided $100 compensation.

2.2. Data collection

We obtained one year of utility data for each household, including hourly metered electricity use and daily metered gas use where available. We conducted one visit to each home, during which we installed a smart thermostat where the heating and cooling system could accommodate the product (Ecobee 3 lite) (n = 40). For homes that could not receive the smart thermostat, we set up a wi-fi connected thermo-hygrometer (Govee H5179). Both devices record data at 15-minute intervals. An accredited energy audit contractor accompanied the research team and performed an ASHRAE Level 2 energy audit at each home.

Participants provided income ranges, so we estimate energy burden based on the arithmetic midpoint, i.e., if a participant reports their income to $25k-50k, the energy cost burden for that household was calculated at the proportion of their actual annual utility bills to $37.5k. We did not apply an equivalence scale to energy expenditure and income because we observed occupancy in some homes to which the published equivalence scales would not readily apply, for example, households with adult children that may live at home for periods of time varying duration and frequency throughout the year. See Supplementary Methods for detail on energy burden calculation.

2.3. Housing quality analysis

To assess participant behavior, we estimate indoor temperature setpoints in two ways. First, we estimate the heating inflection temperature (HIT) (ambient temperature at which a household begins heating) for each home using a splitwise regression of metered daily gas use on hourly average ambient air temperature (obtained from NOAA Local Climatological Data (LCD) for the data collection period). Second, we evaluate the observed heating and cooling setpoints and the observed indoor temperature for the heating and cooling season for a subgroup that received a smart thermostat (n = 40). We calculate cooling and heating season means for setpoint temperature as well as the standard deviation for setpoint and indoor temperature using this interval data.

2.4. Heat pump cost analysis

Our energy cost analysis for switching to all-electric heat pumps from natural gas-based heating consists of three steps. See Appendix A for detailed calculation methodology and model specifications.

- *Heat load calculation. Existing furnace gas use.* To determine heating natural gas use, we first estimated the inflection point for temperature dependent gas use using a split-wise regression of heating degree hours (a measure of the intensity of the space heating needed for a given time and place) on hourly total gas use. We assumed that the slope of the piecewise linear function (found with the segmented() function in R) past this inflection point indicates heating related natural gas usage. From that, we derived the slope which is the natural gas usage per heating degree hour. We then obtained the amount of gas used during each hourly time step for heating by multiplying the slope by the difference between the outside ambient air temperature departure from the indoor heating setpoint gathered during the initial data collection period when the energy audit took place.

Deriving heat load. We multiplied the hourly gas use by the furnace efficiency to obtain the hourly heating load for each house. We obtained the hourly ambient temperatures for each home during the window of time the utility data was provided by the utility (e.g. 11/10/2020–11/11/2021) using the NOAA Local Climatological Data (LCD) Tool for the closest available weather station.

- *Heat pump model.* We calculated the heat pump hourly temperature-dependent coefficient of performance (COP) using the following equation:

$$COP_i' \times (1 - l(t_i)) = COP_i \; Tmin < t, \; i \in 8760$$

$$COP_i = 1 \; t < Tmin$$

Where:

i indexes hour;

COP' = manufacturer reported coefficient of performance using the efficiency curve (ambient temperature vs. COP) of the Mitsubishi M2i cold climate ASHP for heating;

$l()$ = defrost efficiency loss for give temperature, t (%);

t = **hourly dry bulb temperature (F)** using the NOAA LCD weather data for the same period for which had metered natural gas data for each home;

COP = observable coefficient of performance;

$T_{min} = 10°F$ reflecting ambient temperature change over point from heat pump to backup heating mode via electric resistance coil;

$<T_{min}$ **COP** $= 1$ reflecting the heating efficiency of an electric resistance coil used for backup to ensure that heating setpoints are met below the change over point.

We calculated percentage improvement in cooling energy by dividing the Mitsubishi H2i SEER rating (SEER = 17) by the on-label AC efficiency obtained from the energy audits for each home. This kind of high efficiency equipment comes with a first cost premium over a standard furnace replacement. It is therefore expensive for low- and middle-income households and is likely not affordable without a subsidy that covers most of the cost. Selecting this equipment is a conservative assumption. We then applied this factor to an average cooling energy percentage obtained from the Resstock End Use Savings Shapes (Wilson et al., 2022) to determine the annual energy cost savings.

- *Energy cost calculation.* We calculated the energy cost using a model we developed in R that takes in the hourly estimated electric and daily gas usage for the hypothetical heat pump scenario and calculates the total bill costs in the manner calculated by the utilities as published in the electricity and gas rate schedules ("DTE Electric Company Rate Book for Electric Service", 2023). For example, to calculate the annual electricity cost for each home, we apply the flat rate service charge per month, capacity and non-capacity energy charges assessed per kWh, as well as surcharges and credits. We completed this process for three electricity rates and two gas rates to test the sensitivity of our results to rates available to participants. See Figure B.7 for rate summary and Note D.5 for rate description. We do not include tariff changes from one year to the next because future rate changes are unpredictable and beyond the scope of the analysis. Changes in consumer behavior associated with changes in utility tariffs are also beyond the scope of the paper and therefore not included in the analysis. Additionally, incorporating behavior changes would not have a meaningful impact on the results because short term elasticities are low for electricity and natural gas in the US (U.S. Energy Information Administration, 2021).

2.5. Resstock

We analyzed the potential for energy efficiency to mitigate cost increase due to heat pumps by calculating energy costs derived from four modeled retrofit scenarios included in the NREL Resstock End Use Savings Shapes database (Wilson et al., 2021). We selected hourly load profiles available for a baseline case and three "upgrades" including full electrification with or without deep efficiency retrofits, and deep efficiency retrofits with no change to the HVAC systems. To these scenarios, we applied the utility rates for all sensitivity cases as described above. We then calculated the mean incremental annual energy costchange resulting from a series of these changes across a random sample of 400 homes in the database representative of Detroit, MI.

2.6. Retrofit cost analysis

The contractor recommended energy efficiency measures and provided first cost and utility cost savings estimates for the recommended work. We used the "Return on Investment and Rebate Report" prepared for each study participant to summarize the recommended energy efficiency upgrades to code the unique efficiency measures recommended across the sample.

The parameters we used for estimating the feasibility of retrofitting were economic payback in years for the package of all recommended retrofits (calculated as the first cost divided by the annual energy cost savings), the first cost of the total package, and the modeled utility cost savings for the individual measures. The values for these parameters were obtained from the retrofit reports provided to participants by the energy audit contractor. The payback parameter described above follows the US Department of Energy Methodology and Procedures for Life Cycle Cost Analysis (Code of Federal Regulations. 10 CFR Part 436 Subpart A). No discount rates are used, making this the best-case estimate of the payback period. Given our findings, the decision to use an undiscounted payback period is conservative: if a discount rate were applied, the payback period would be even longer, strengthening our argument that the retrofits are not attractive on the basis of utility bill savings. Additionally, we show the rates that participants were provided as part of their energy audit, so payback periods not inclusive of a discount rate are more representative of the data participants have to inform their decision making.

3. Results

We find that electrifying homes with heat pumps increases annual energy cost by 58 % on average (range: 11–182 %) when compared to natural gas heating and considering a flat electricity rate, higher than previous estimates. This change exacerbates already high energy burdens for low-and-moderate income (LMI) households. While we find energy retrofit opportunities that saved energy cost for every home, they came with substantial obstacles that could limit uptake. There is an average payback period of 24 years and homeowners can be left without sufficient information to act, even after a visit from a home energy auditor. Willand et al. (2020) identified this situation as the retrofit trap in their 2020 analysis of Australian home retrofit programs. It can be understood as a form of poverty trap, defined Azaiadis and Stachurski as a reinforcing mechanism that acts as barrier to adoption of techniques that can alleviate poverty (Azariadis and Stachurski, 2005). The clean energy transition is hindered by an energy poverty trap because the extensive retrofits needed to make electrification affordable are themselves too expensive for low-income households.

3.1. Housing quality vs. set-point choices

We estimate energy burden for each household by calculating the proportion of their annual combined electricity and gas cost (sourced from utility bills) to the self-reported income range. The 5 highest energy burdened households have rates ranging from 10 to 40 %. 32 % of homes have energy burdens greater than 6 %, which is considered a high energy burden and twice the national average (Drehobl et al., 2020). All these households have below-median incomes. 37 % are between 3 and 6 %. 31 % of homes have an energy burden below 3 %; all but one of these homes have incomes that exceed the local median (see Figure B.1). See Table C.1 for descriptive statistics on utility costs and energy burden. Table C.6 provides a list of self-identified household income ranges and a comparison to the area median income (AMI) by zip code.

Not all homes in our sample were of the same age and quality. The homes were on average 60 years old and built in an era during which Michigan did not have energy efficient building codes.[2] These codes were adopted for the first time 1977 when ASHRAE 90–1975 was adopted state-wide ("US Dept. of Energy Building Energy Codes Program", 2024). 13 homes (5 in the <$25k income group and 8 in the $25–50k group) had been retrofit by Habitat for Humanity of the Huron Valley (Habitat) resulting in higher quality for their age. Improvements had been made 1–10 years prior to participating in this study.

Homes retrofit by Habitat perform consistently better than market rate homes in the sample [Fig. 1]. To understand the impact of these

[2] They were adopted for the first time 1977 when ASHRAE 90-1975 was adopted state-wide. (US Dept. of Energy Building Energy Codes Program, www.energycodes.gov/status/states/michigan).

retrofits on overall home energy efficiency, we examine the difference between trends of annual energy use per unit floor area (or energy use intensity) and per occupant across income in market rate homes compared to the Habitat homes. When treating self-reported income categories as an ordered set (<$25k, $25–50k, $50–75k, and >$75k) in a least squares regression of energy use intensity (EUI) per occupant on income, we find a significant downward trend (p-value=0.048) for market-rate homes, indicating that low-income households either live in less energy efficient homes or there is significantly different behavior across income levels.

The latter explanation would suggest, for example, that lower-income households start to use heating at higher ambient temperatures and cooling at lower ambient temperatures. Cong et al. provide evidence to the contrary. They find that lower-income families wait for ambient temperatures to rise higher before turning on air conditioning compared to those with higher incomes (Cong et al., 2022). This would imply that low-income families use less energy, a seeming contradiction of our results. However, we believe that there is no contradiction, since the Cong et al. results are not directly comparable to ours for two reasons. First, we report energy use per square foot per occupant, which Cong et al. do not observe. Second, Cong et al. have studied air conditioning, whereas energy use in our sample is dominated by heating. Huang et al. (2023) do find evidence that low-income households start to heat earlier in the season and heat for more months of the year than higher-income households. However, these results are also not comparable to ours since there is no normalization by area or occupancy. We estimate the heating inflection temperature (HIT), or the outdoor temperature at which each household turns on the heat because in every case heating constitutes the highest proportional energy expenditure (>60 %). To estimate the HIT, we calculate a linear splitwise regression of metered daily gas use on ambient air temperature. We find no significant trend in HIT across income (see Figure B.2). Combined, our findings and those of Huang et al. (2023) suggest that behavior-driven energy use patterns are unlikely to explain the higher energy use of low-income homes.

Observed heating and cooling setpoints—read from participants' smart thermostats—likewise reveal that lower income households do not on average choose higher setpoints in winter or lower setpoints in summer [Fig. 2a]. We do observe greater variance in the set points that households in the lowest income group (<$25k) choose [Fig. 2b], as well as in the indoor temperatures that they experience [Fig. 2c]. This suggests that, even though they have higher energy use intensity, these households are actively trying to manage their energy use and comfort by manipulating their set points. This provides evidence that the higher EUI is in fact due to poorer building envelopes and not because lower-income households are choosing consistently different setpoint temperatures.

We look at housing characteristics to explore whether the homes occupied by low-income households are in fact less efficient. Blower door testing conducted at each home provides an empirical measure of efficiency by measuring air infiltration. Low infiltration signifies high efficiency. We find that the homes retrofit by Habitat have better performance than market-rate homes in the sample. The median measured air infiltration rate of Habitat homes is almost half that of their counterparts (4.2 ACH 50 and 7.7 ACH 50, respectively) with less variability (range: 2.9–5.9; IQR = 3.4–5.3 and range: 3.2–17.5; IQR = 5.8–10.9, respectively). Applying the same regression method described above, after excluding Habitat homes, we find a significant downward trend (p-value = 0.023) for market-rate homes, indicating that the lower-income homes are indeed less efficient (Figure B.3).

3.2. Energy burden

For the 51 houses in our sample, we calculate the electricity loads that would result from replacing natural gas furnaces with air source heat pumps for space heating (see Supplementary Methodology for more detail on reduced complexity model and load derivation) and apply the most prevalent gas and electric utility rates across the sample to determine the energy cost change associated with this replacement. We calculate change in annual energy bills and energy cost burden which refers the difference in energy expenditures and percentage of income spent on utilities, respectively, between the baseline scenario and the heat pump scenario. 41/51 households were on a standard time-invariant rate, which will be discontinued as of May 2023. 10 had elected different rate structures, which include time-of-use rates, interruptible cooling rates, and specialty rates designed for low-income households. We find that switching to a heat pump would increase annual utility bills for every household in the sample, and that the cost goes up by $1154 on average (see Table C.3).

Our results show variability in median cost change across income and a disproportionate concentration of high energy burden increase below median income (<$25k and $25–50k). The median cost increase for below median income households is $801 ($n = 28$), constituting a 37 % utility spending increase on average. There is a 49 % utility spending increase for above median income households on average ($n = 22$) [Fig. 3a-1]. Even though the median cost increase is nominally lower for

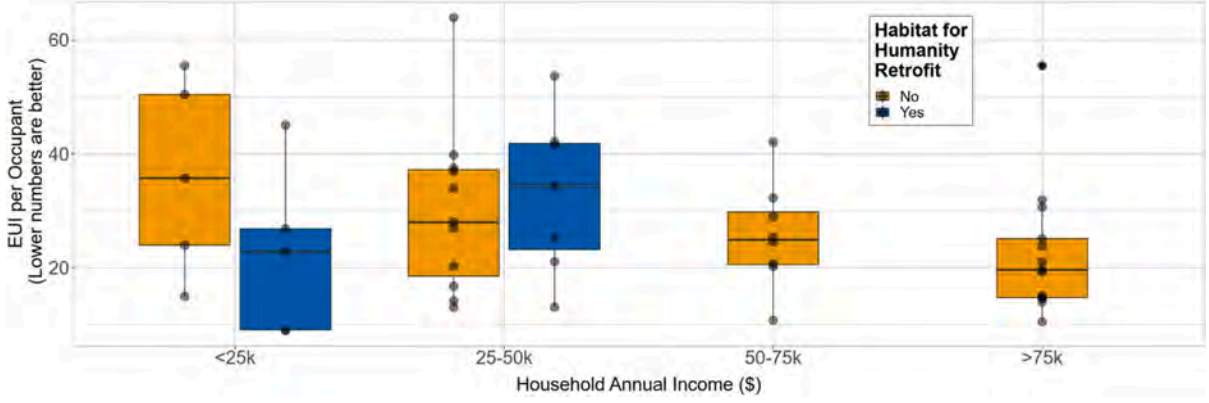

Fig. 1. Energy use intensity per occupancy by income group. Annual energy use per floor area divided by the number of occupants is shown here. The x-axis represents four income categories to which participants were assigned given the income range they provided. Each box plot shows the median (middle line), first and third quantiles (lower and upper box bounds), and minima and maxima (whiskers). The blue boxes represent homes that have been retrofit by habitat for humanity, which perform better than market rate homes in the sample (represented by oranges boxes) for homes earning less than $25k. Each dot represents one household. Using a non-linear least squares regression, we find a significant downward trend (p-value = 0.048) among market rate homes, indicating that those with lower incomes live in less efficient homes.

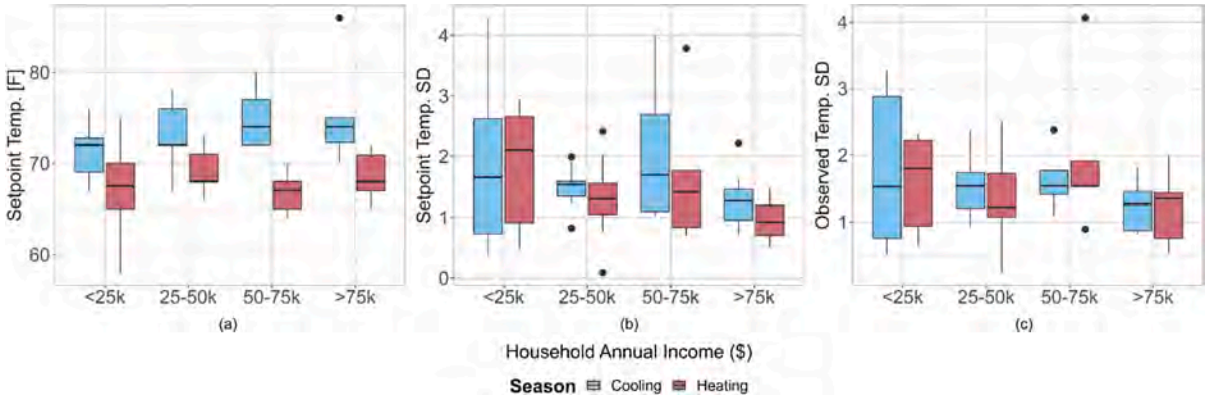

Fig. 2. a-b-c: Thermostat setpoint and observed indoor temperature by income. Observed heating and cooling setpoints (a), setpoint standard deviation (b), and indoor temperature standard deviation (c) on smart thermostats for each home.

below median income households, their energy burden increase is 4 times higher on average than those at or above median income [Fig. 3b-1]. Additionally, all households earning median income ($50–75k) and above (>$75k) - which currently have a median energy burden of 2.6 % – would experience a median change in energy burden of greater than 1 percentage point, indicating that energy burden could become a concern for households which are currently energy secure.

3.3. Time of use electricity rates

We examine the impact of two time-of-use rates available to all customers in the study region on the annual increased utility costs and energy burdens of the sample for a hypothetical conversion to heat humps. Switching to the standard time-of-use rate (DTE no. D1.11) ("DTE Electric Company Rate Book for Electric Service", 2023) reduces the mean cost increase for the sample by $120 per year from $1154 to $1034 (see Fig 3a-2) relative to a flat rate. Under this rate, the median

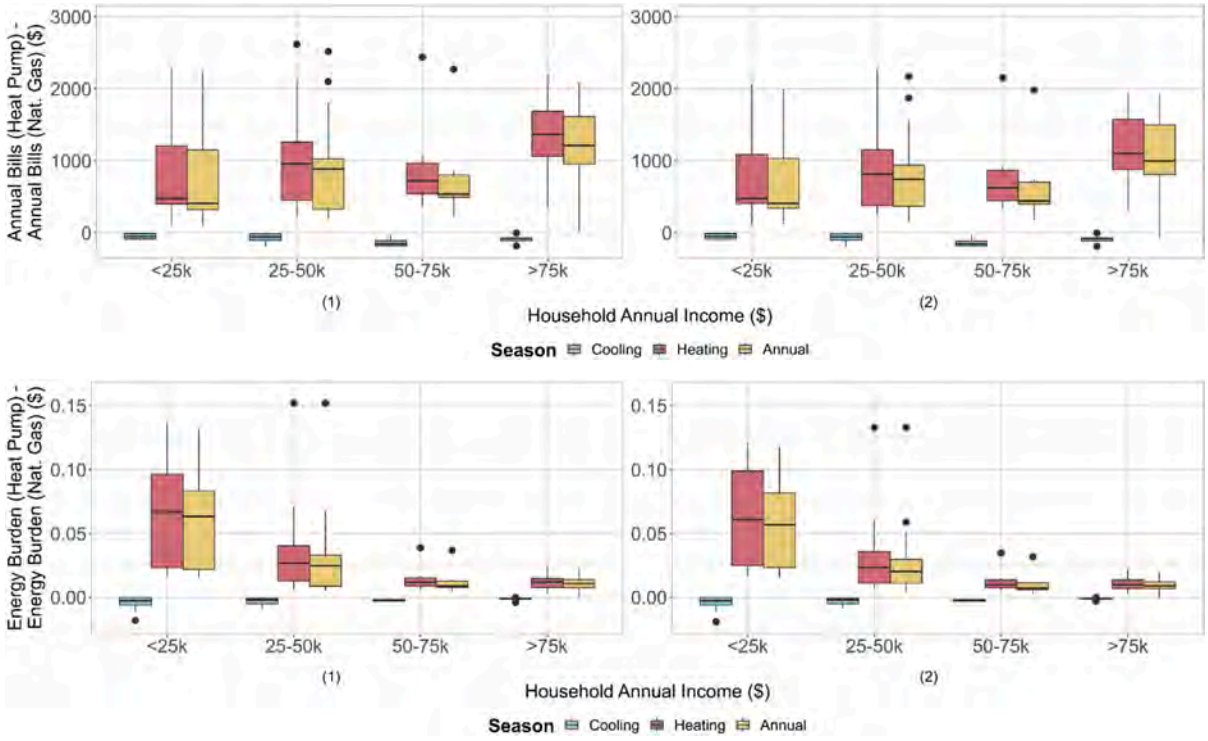

Fig. 3. a: Change in annual energy bills for switching to a heat pump from natural gas heating by income. The x-axis represents four income categories to which participants were assigned given the income range they provided. Dot represents outliers. Each box plot shows the median cost increase (middle line), first and third quantiles (lower and upper box bounds), and minima and maxima of change in utility cost change for (1) standard flat electricity rate and 2022 natural gas cost; (2) standard time-of-use electricity rate and 2022 natural gas cost.
b: Change in energy burden for switching to a heat pump from natural gas heating by income. The x-axis represents four income categories to which participants were assigned given the income range they provided. Dot represents outliers. Each box plot shows the median energy burden increase (middle line), first and third quantiles (lower and upper box bounds), and minima and maxima of change in energy burden change for (1) standard flat electricity rate and 2022 natural gas cost; (2) standard time-of-use electricity rate and 2022 natural gas cost.

utility cost change due to heat pumps is lower for every income category. The effect of this lower cost change is minimal for energy burden, reducing the rate by less than 1 percentage point for each category [Fig 3b-2].

By comparison, relative to a flat rate, the optional time-of-use rate (DTE no. D1.2) (DTE Electric Company Rate Book for Electric Service, 2023) would worsen the increase in annual utility cost for switching to a heat pump for all income groups. Switching to D1.2 increases the mean cost increase for the sample by $623 per year to $1777 (see Figure B.4). This rate nearly doubles the median energy burden changes for all income groups earning less than $75k (see Figure B.5). The D1.2 rate had a higher cost per kWh at peak times and a peak window two hours longer than the D1.11 rate. These rates impacted each household differently given the variety of occupants, schedules, housing vintage across the sample. For instance, those who saw the greatest cost increase with the standard time-of-use rate had the oldest, least efficient AC units in the sample and used their cooling systems during the peak window, whereas, in reality, the switch to a heat pump would include a new, more efficient AC.

While the gas commodity prices have risen dramatically from 2021 to 2023, the delivered price of natural gas for residential customers has in fact been modest and does not affect the results. See Figures B.4 and B.5 for a comparison of annual bill and energy burden changes with 2021 and 2023 gas rates. See Table C.2 for a detailed comparison of all of the electricity and gas rates available to DTE customers as of 2023 and their impact on baseline household energy use.

3.4. Energy retrofit model

Energy retrofits are a possible strategy to mitigate this increase in bills. Since we do not have empirical estimates of cost savings potential of envelope improvements to mitigate the cost increase of heating electrification, we first model the corresponding energy uses using the NREL ResStock End Use Savings Shapes (Wilson et al., 2022). We randomly sample 400 Michigan homes heated with natural gas from the database and examine four scenarios: baseline envelope with natural gas heating, envelope upgrade, heat pump upgrade, and combined heat pump and envelope upgrade. To then convert the energy uses to cost, we apply the electricity and gas rates experienced by 41/51 of our study participants to the hourly electricity and gas loads to estimate the relative cost impact of retrofits for the natural gas scenario and the heat pump scenario.

We find that transitioning to a heat pump without energy retrofits results in a mean utility cost increase of 26 % over the baseline. Adding a comprehensive envelope retrofit improvement mitigates this cost premium and drives utility costs back to what they were with natural gas heating with the existing envelope. Energy efficiency retrofits alone reduce bills by 11 % compared to the baseline condition [Fig. 4].

See Note D.1 for a comparison of the modeled results to the estimates calculated using observed data from the field study, including a breakdown of model findings by house vintage (Figure B.6).

3.5. Contractor retrofit recommendations

Our results suggest that, with energy retrofits, most homes would not experience an increase in utility bills relative to the status quo if they shifted to heat pumps. Based on REM/Rate (REM/Rate 2024), commonly used software, our contractor recommended a different combination of ten individual retrofit measures for the homes in our sample and these upgrades are expensive with long payback periods. The most commonly recommended measure is air sealing, an intervention in which joints are sealed to reduce air infiltration. We classify building envelope upgrades as simple if they can be completed by one contractor (e.g., spraying cellulose in the attic) and complex otherwise (e.g., foam injection into drywall). Upgrades to the HVAC system are in a separate category, as are upgrades to other appliances (e.g., fridges) (see Figure B.8). The median retrofit package costs are about 10 % of household income. ($3250 for <$25k; $4700 for $24–50k; $10,300 for $50–75k; $7000 for >$75k) (see Figure B.9). 14 households in the lowest three income groups are faced with total package costs of more than 20 % of their income. The median payback period across the sample is 24 years, with a large variance across the income groups (see Figure B.10).

Upfront cost and simple payback estimates for retrofits match previous studies. Fowlie et al. (2018) use empirical estimates for actual energy savings across the Michigan WAP and find internal rates of return (IRR) at −10.6 % (10 year), −2.3 % (16 year), and 0.21 % (20 year). We find even lower IRR for the recommended retrofits by the energy

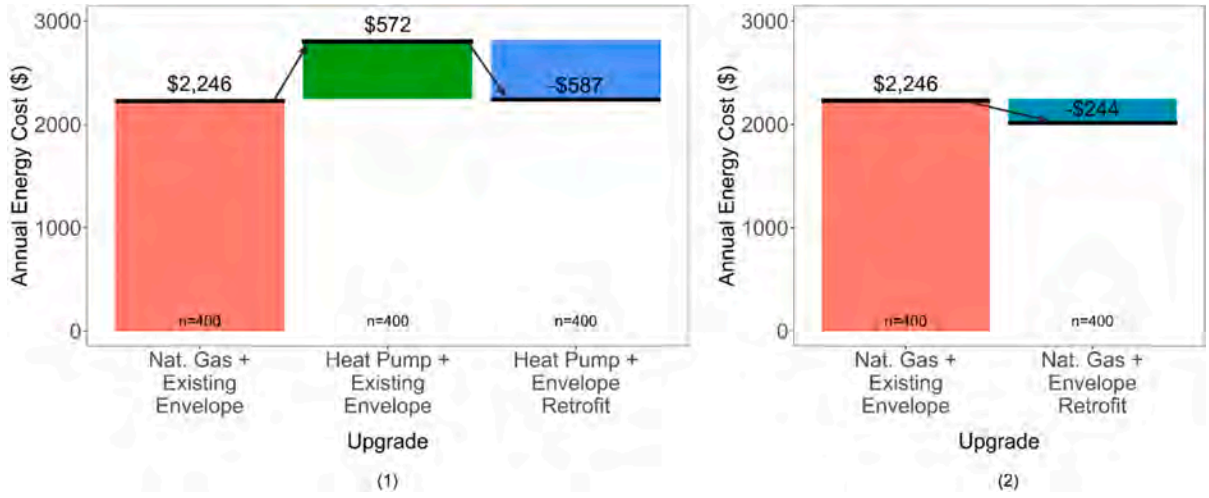

Fig. 4. Modeled mean annual energy cost impact of heating electrification and envelope improvements. (1) The baseline case (natural gas heating with existing envelope) represented in red is compared to two upgrades: heat pump with efficient envelope retrofit (green) and heat pump without envelope improvements (blue). (2) The baseline case (natural gas heating with existing envelope) represented in red is compared natural gas heating with efficient envelope retrofit (teal). Means represent 400 randomly sampled homes from the ResStock end use load profile database that use natural gas in Michigan. Using a Kruskall–Wallace test, we find a significant difference between the medians of the utility costs in each upgrade category (p-value < 0.01). We test the null hypothesis that the medians were the same using a pairwise with the Bonferroni adjustment and similarly find significant differences for each comparison.

assessment contractor: −16.1 % (10 year), −5.3 % (16 year), and 2.2 % (20 year). Less et al. (Less et al., 2021) estimate an archetypical retrofit package for a single family house that includes the most common retrofit recommendations in our sample (attic floor insulation, air sealing, foundation floor insulation) based on actual US construction costs at $7825 (see Note D.2 for measure cost calculation). The mean upgrade package cost estimated by the energy audit contractor in our sample is $7628 and the median is $5900 (see Figure B.9). Since the package described by Less et al. excludes system or appliance measures, we surmise that it is likely our contractor's costs are underestimates. Realized project costs could be higher, and payback periods longer.

There is no clear pattern about what measures are most cost-effective. The results show a large range of annual cost savings available from the recommended retrofit packages, with annual utility bill savings ranging from $26 to $730 [Fig. 5a]. We find that air sealing, which was recommended to all households, provides a payback range of 3.7 to 144 years [Fig. 5b] and attic insulation alone provides a payback range of 20 to 259 years (see Note D.2 for measure cost calculation). The high-end estimates that reflect payback periods much higher than seen in the literature are due a sample-specific scenario in which 25 % of the homes in the study received energy efficiency retrofits before the study period. For these homes, which were already high performing, the contractor recommended improvements to existing conditions (such as attic insulation and air sealing), which resulted in marginal energy savings and therefore long payback periods.

4. Discussion

We explored the drivers of energy inefficiency, explored the economic impact of replacing natural gas furnaces with heat pumps by income, assessed a range of energy retrofit measures that could support utility cost reduction in the 51 Michigan households we studied, and compared this impact to estimates from a national model. Heat pumps raise energy cost and energy burden disproportionately for low-income households. The median utility cost increase for switching to a heat pump is lowest for low-income households because they use the least amount of energy. This finding is suggestive of an efficiency paradox (Goldstein et al., 2022) where the lowest consuming households live in the least efficient homes, indicating that they are likely not using enough energy to meet their health, safety, and comfort needs. Yet, the increase in energy burden is disproportionately higher for low-income groups because even though their cost increase is nominally the smallest, it is a greater percentage of their annual income. Our results show that adopting heat pumps results in a fmedian energy burden increase of 75 % and 54 % for both income groups earning below AMI (<$25k and $25–50k, respectively). Given that households below median income have a 6 % median energy burden on their existing natural gas heating systems, such increases would severely worsen existing energy insecurity, for instance increasing risk of poor health (Reames et al., 2021) and coping behaviors like trading off paying utility for paying for rent or food (Hernández, 2016), or the underconsumption of energy in household who struggle to pay their bills (Meyer et al., 2018; Barrella et al., 2022; Faiella and Lavecchia, 2021; Antepara et al., 2020).

Policymakers should act to help lower the operating costs of heat pumps compared to natural gas for low-income households in cold climates. This can be done in three ways. First, government-sponsored initiatives to advance more efficient heat pump technology like the U.S. Department of Energy Residential Cold Climate Heat Pump Challenge are essential to improve energy bill affordability of fuel switching. More efficient heat pumps reduce the utility cost premium over natural gas furnaces.

Second, state regulators should exercise a more robust scrutiny of utility company returns and create more opportunities to improve customer outcomes in the rate making process. For example, the Michigan Public Service Commission recently ruled in a disputed rate case in the study region that resulted in allocations for energy retrofits in historically underserved areas due to intervening efforts from customer groups not typically represented in rate making like community

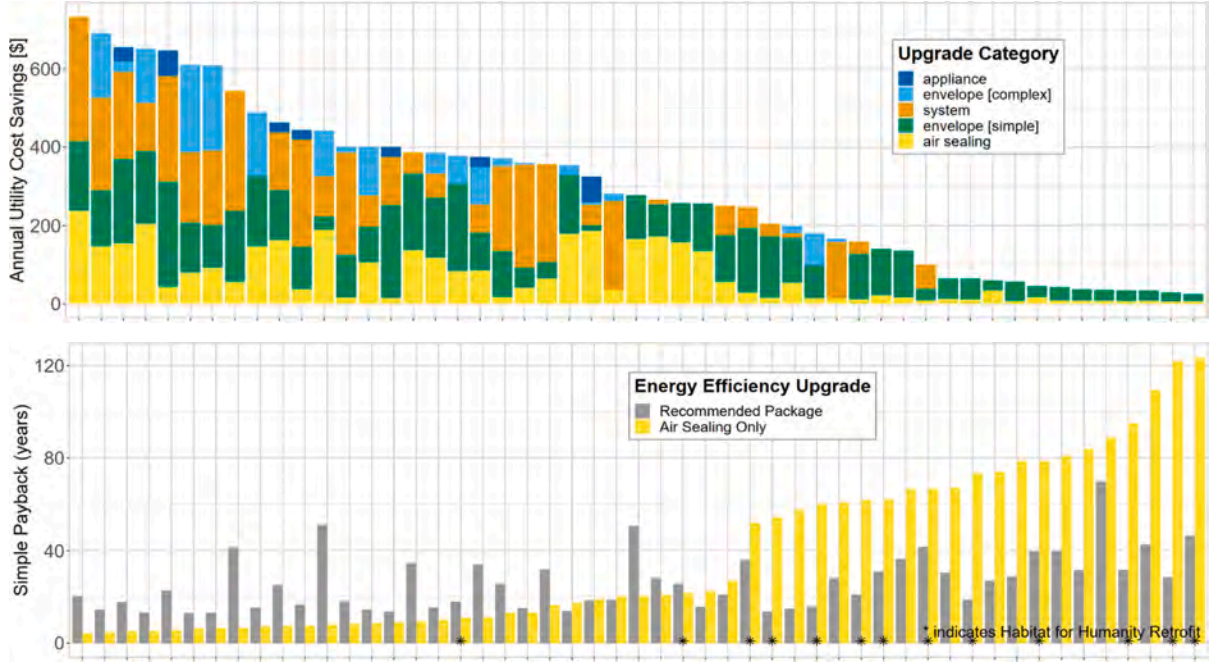

Fig. 5. a: Annual utility cost savings for retrofit packages by household. Colors represent categories we develop to indicate the relative cost and difficulty of adopting the recommendation. There is no clear pattern for which energy retrofits provide the best payback.
b: Simple payback for the recommended package and air sealing by household. Gray bars represent the payback for the full retrofit package recommended for each home. Corresponding yellow bars represent the air sealing payback period for that home. Star indicates houses that have been retrofit by habitat for humanity.

advocates and municipal governments (Hon et al., 2023). A high ratio of per-unit electricity to gas rates makes heat pumps less attractive than natural gas furnaces.

Third, states should consider implementing percentage of income payment plans (PIPP) that place a cap on energy expenditures relative to household income. These programs can be paired with federal- and state-funded retrofit programs to simultaneously improve the building stock and mitigate energy poverty. Capping household utility costs insulates low-income households from increase in bills.

Local factors exacerbate the economic penalty for household heating electrification described in this study and pose additional barriers to change not found in other regions. In our study sample, the average electricity cost is $0.18 per kWh and gas costs $0.8 per 100 cubic feet, or $0.03 per kWh. Per unit energy, electricity is therefore 5 times more expensive than gas, which is a large-enough difference that the higher efficiency of heat pumps is unable to compensate for it. (See Table C.4 for energy burden changes by income). Our results show that under these circumstances, energy cost increases for heating electrification could be disruptive even for households earning twice the median income.

Low-income households will need expanded and flexible financial assistance to retrofit their homes to prepare them for electrification. The subset (25 %) of homes that received deep energy retrofits prior to the data collection period had consistently more efficient air sealing and attic insulation than the market-rate homes. Retrofits to improve the performance of these characteristics were the most frequently recommended to study participants by the contractor, but we found they had a large range in payback period. There was no clear best choice investment that would provide either the greatest utility savings or the best payback, making it difficult for policymakers to make broadly-applicable recommendations for energy efficiency retrofits.

The group of very low earners (<$25k) with low energy burdens living in highly efficient homes were the same households that experienced the lowest energy burden increase due to heat pumps. This demonstrates the value of energy efficiency improvements in buffering households from the impact of utility cost rise due to electrification. However, the retrofits that provide the remedy are expensive. Our findings suggest that actual upfront costs for recommended retrofits in homes that have not been renovated far exceeded the $7700 cap for the Weatherization Assistance Program. Additionally, the payback periods in many cases were so high the projects would not qualify for the program, which requires a 1:1 saving-to-investment (SIR) ratio without consideration of discount rates. Current programs need to be expanded to cover the cost of expensive upgrades, and to be made available to more homes.

5. Conclusions

Policy action is needed to make heating electrification viable. The economics of electrification are adverse for the existing housing stock in cold climates. Our findings suggest that heat pumps are not a feasible economic alternative for households currently using natural gas, unless governments offset energy cost premiums through public funding. Some of the policy discussion around heat pumps does not acknowledge this (U.S. Department of Energy, 2023; Rewiring America, 2021; Fathollahzadeh et al., 2022). Such an investment can be justified on the basis of equity and by internalizing the social cost of carbon, current estimates of which are ~$180 per ton CO2 (U.S. Environmental Protection Agency, 2022; Rennert et al., 2022).

Coupling heating electrification with retrofits in existing homes with natural gas heating can limit utility cost increases and reduce a key barrier to heat pump adoption. At the same time, our study shows that even after a visit from a home energy auditor, homeowners can be left without sufficient information to act. The reports they are provided could be more useful in supporting investment decisions by providing a marginal abatement curve specific to each house, where the payback period of each measure is plotted against the cumulative cost of all the recommended measures. The homeowner can decide the most they are willing to spend, and the curve would show them all the fastest-payback measures that can be implemented for that amount.

The impact of rate structures should be analyzed based on empirical data from the rate base. Time-of-use rate design for electricity determines the cost increase for switching to heat pumps. We estimate that one rate (D1.11) reduced the increase in bills by 10 % compared to the flat rate (D1), while the other (D1.2) further elevated the average cost increase by 56 %. Modeled results using ResStock show the opposite, where the D1.11 rate is usually no worse than the flat rate (see Figure B.7 for utility rate comparison). Using empirical energy use data in utility rate design to understand how proposed rates affect households across the income spectrum and across housing quality given future adoption of heat pumps could help mitigate energy insecurity and promote greater access to heat pump adoption among natural gas users.

While our focus on Michigan allows us to understand the cost dynamics for electrification in a cold climate with high prevalence of natural gas use, limitations of our study include the small sample size and the limited regional scope. Additionally, we were unable to incorporate homeowner attitudes regarding converting their natural gas heating systems to electric heat pump systems. Future work will investigate these perceptions, examining the factors that influence decision making for residential electrification and further examining potential barriers to equitable adoption of heat pumps across income.

Energy Star Formulas

COP — The COP is a measure of the amount of power input to a system compared to the amount of power output by that system. The COP is therefore a measurement of efficiency; the higher the number, the more efficient the system is. The COP is dimensionless because the input power and output power are measured in Watt. The COP is also an instantaneous measurement in that the units are power which can be measured at one point in time.

$$COP = \frac{\text{useful output}}{\text{energy input}} \quad \text{(Eq 1)}$$

SEER — the SEER is the ratio of output cooline enerev (in BTU) to electrical input enerev (in Watt-hour). However the SEER is a representative measurement of how the system behaves over a season where the outdoor temperature varies

$$SEER = \frac{\text{output cooling energy in BTU over a season}}{\text{input electrical energy in Wh during the same season}} \quad \text{(Eq 2)}$$

EER — How do you convert SEER to EER?
Typical EER for residential central cooling units = 0.875 × SEER. SEER is a higher value than EER for the same equipment.

COP — HSPF 10 = 2.93 COP

10	HSPF		3.6	COP	12.28668942
2.93	COP				

HSPF — Like SEER, this is a measurement of the efficiency of a system and the units are the same (BTU/h divided by Watt). However, this measures the efficiency of the system in heating mode, not cooling mode. Therefore it applies only to heat pumps or reversible air conditioning units and not to units that only cool a space.

The HSPF's formula:

$$\text{HSPF (heating seasonal performance factor)} = \frac{\text{The heating output in the (coldest) region}}{\text{Total electric use for the same region}}$$

KW/Ton — The efficiencies of large industrial air conditioner systems, especially chillers, are given in kW/ton to specify the amount of electrical power that is required for a certain power of cooling. In this case, a smaller value represents a more efficient system.

$$COP = \frac{\text{power output in } \$ \text{ (or BTU)}}{\text{power input in } \$ \text{ (or kW-hr)}} \quad \text{(Eq 3)}$$

80% annual fuel utilization efficiency (AFUE) furnace (the current federal minimum efficiency standard)5
90% AFUE furnace (the most common high-efficiency furnace and the ENERGY STAR® level for the North)
97% AFUE furnace (the ENERGY STAR Most Efficient level)
Geothermal Energy star DGX - EER 16, COP 3.6
8.2 heating seasonal performance factor (HSPF) heat pump (current federal standard for split systems)
8.5 HSPF heat pump (the ENERGY STAR level)6
10.3 HSPF heat pump (the ENERGY STAR Most Efficient level)7
A cold-climate electric heat pump. This is a very preliminary analysis based on one field test that found a seasonal 2.8 coefficient of performance (COP) in Connecticut. More products and data are needed.

Formulas

Conductive Required Heating Energy	mmbtu/day	(Area*degree days*24 hours*U Value)/1000000
Infiltration Required Heating Energy	mmbtu/day	(Space vol*Delta Temp*air changes/hr*heat factor* 24 hours)/1000000 The air infiltration heat loss is uncontrolled heat loss through joints in the construction and cracks around doors and windows. This figure is affected by wind and pressure differentials between the outside and interior of the home which causes air to move inside the home, thereby producing heat loss as that air escapes the room. The heat capacity of air at sea level is, on average, 0.018 Btu per cu. ft. per degree F.

Retrofit

ABSTRACT

Residential heat pumps could reduce greenhouse gas emissions, but increase energy burdens, the proportion of income households spend on utility bills. We analyze utility bills, thermostat settings and energy burdens for a sample of 51 households in Michigan, half below median income. We recruit a contractor to conduct energy assessments of these households and provide them with energy retrofit recommendations, including estimated costs and savings. We find that low-income households choose similar temperature setpoints to higher-income households, but live in less efficient homes. Below-median income households, which today experience a median energy burden of 6 %, would see it rise to 10 % if they shifted to electric heat pumps from natural gas. Weatherization could offset this increase, bringing burdens down to pre-electrification levels. However, median payback is 24 years, making retrofits infeasible for the poorest. Our results are indicative of an energy poverty trap that could hinder an equitable energy transition.

Spotlights

- Converting fossil-fuel based home heating to electric could reduce pollution but make bills less affordable.
- Switching to electric heating results in low-to-moderate income households paying a high percentage of income on energy.
- Retrofitting homes could make electric heating more affordable but it is expensive and therefore infeasible.
- High-cost energy efficiency home retrofits could hinder an equitable energy transition.
- Future work will investigate homeowner attitudes regarding electrifying their homes and barriers to equitable transition.

1. Introduction

In recent years, US state policy (Climate Leadership and Community Protection Act 2020; An Act Creating 2022; Climate Commitment Act 2022)) has signaled a commitment to reducing greenhouse gas emissions by transitioning home heating from fossil fuels to electricity. U.S. federal policy has sought to use subsidies to lower the upfront cost of heat pump adoption (Inflation Reduction Act, H.R. 5376). Electrification has been projected to increase annual utility cost for households in more than half of US states (Vaishnav and Fatimah 2020; Deetjen et al., 2021), with the worst effects in cold climates (Walker et al., 2022). Rising energy costs could have a large impact on households across the income spectrum.

1.1. Literature review

Higher utility bills could increase the economic and physical hardships in households already experiencing energy insecurity. A quarter of American households spend a high proportion (>6 %) of their income on utilities, defined as energy burden (Drehobl et al., 2020). High energy burden is associated with poor health outcomes (Reames, 2016), and households with certain vulnerabilities, such as older adults, choose uncomfortable and sometimes unsafe indoor temperatures to reduce bills (Cong et al., 2022). Lewis et al. center deteriorated housing conditions concentrated in racially segregated neighborhoods in their discussion of energy insecurity, which encompasses financial, behavioral and physical hardships related to home energy use (Lewis et al., 2020).

Households with lower energy burdens are not entirely precluded from the effects of higher ongoing costs associated with heating electrification because these costs are associated with building

characteristics that are prevalent across the US housing stock. Old homes heated by natural gas have been shown to result in the greatest operational costs for heating with a heat pump (Vaishnav and Fatimah, 2020). 64.5 million American homes use natural gas for heating and 57 % of them were built before energy codes were implemented in the US (U.S. Energy Information Administration, 2023). Knowledge of household demographics, housing characteristics, and occupant behavior are essential to understanding the barriers to equitable access to heat pumps and a just distribution of harms and benefits associated with policy that facilitates the clean heating transition.

Current research about residential energy equity includes only one or two of these critical components. Studies that quantify the link between racial disparities in energy use and housing quality (Goldstein et al., 2022; Bednar et al., 2017), and demonstrate that households of color are more likely to have trouble paying their bills (Graff et al., 2021) do not take into account behavior. Studies that evaluate specific retrofit opportunities and quantify their the savings potential by employing national scale modeling do not address behavior impacts associated with those changes (Bradshaw et al., 2014; Wilson et al., 2019). Likewise, studies that examine the economics of heat pump adoption for low income households, whether in observed system performance (Ceglia et al., 2022; Flower et al., 2020; Calver et al., 2022; Pastore et al., 2022; Liu et al., 2018) or simulations (Donaldson and Lord, 2018; Barrella et al., 2020; Liu et al., 2020; Abbasi et al., 2022; Savage et al., 2022) focus on housing and heat pump technology characteristics without an empirical analysis of occupant behavior and preferences for heating and cooling.

Several recent studies examining the energy savings potential of residential retrofits in the European context point to the importance of incorporating household behavior in home energy assessments (Palma et al., 2022; Barrella et al., 2020; Koasidis et al., 2022; Domínguez-Amarillo et al., 2020). The literature addressing the effect of energy consumption behavior on the cost effectiveness of energy retrofits in the US commonly uses economics theory and analysis. Gillingham and Palmer (2014) conducted a literature review of explanations for limited uptake of home energy efficiency including that flawed decision making could reduce the utility of energy efficiency to customers. Three studies followed that examined this question using home energy efficiency project data from the US Department of Energy Weatherization Assistance Program (WAP). Zivin and Novan (2016) measure the treatment effect of retrofits on energy use of 275 households and provide evidence that electricity savings due to WAP are overstated. Allcott and Greenstone (2017) and Fowlie, Greenstone and Wolfram (2018) use large samples of primary empirical data to estimate the benefits of providing energy efficiency services to low-income homes. Though these studies consider behavioral explanations for under performance of projects compared to engineering estimates, they do not provide detail on the housing conditions prior to intervention or the specific work performed. See Table C.7 for a comparison of this paper's contributions to those of the literature.

Other large empirical studies that address impacts of high utility costs on vulnerable households similarly do not provide data on the housing characteristics of the populations they examine (Cong et al., 2022; White and Sintov, 2020), and therefore do not address why these impacts occur. Although Booth and Choudhary (2013) estimate the rebound effect, identify specific upgrade parameters, and focus on public housing in their assessment of uncertainty in retrofit performance (Booth and Choudhary, 2013), they do not address the transition in heating technology. Recent research has signaled the potential for heat pumps to contribute to residential sector clean heating transition where countries push for climate action and fossil fuels remain the predominant fuel source (Fitó et al., 2021; Thomaßen et al., 2021; Besagni et al., 2020).

1.2. Research gaps

There remains a gap in quantifying the impacts of residential heating electrification across income and in examining interventions specific to both housing quality and energy consumption behavior. Previous studies that have taken this form to assess the reasons for disproportionate impacts of energy cost across income (Cong et al., 2022; Jones et al., 2023) only examine it in the context of air conditioning, not heating. To bridge this gap, this study aims to disentangle the sources of inequality embedded in the economic impact of heat pump adoption and assess fixes available for real homes. The present work has three main contributions. First, we provide evidence that energy burden impacts across income are associated with housing quality rather than behavior. Second, we compare economic impact of heating fuel transition across income groups. Third, we test the idea that there is a way to mitigate the utility cost premium for heat pumps.

We conduct a year-long field study of 51 homes in Southeast Michigan, during which we perform a comprehensive energy audit of each home to observe envelope and HVAC system characteristics, including thermal imaging to identify temperature gradients indicative of air leakage and poor insulation, and blower door testing to measure air infiltration rate, as well an examination of the on-label efficiency of all appliances. We gather metered daily gas and hourly electric consumption data over the study period and collect energy assessment contractor recommendations for energy efficiency retrofits for each home. Our approach to examining residential energy equity is novel because we compare results derived from observed data with simulations derived from statistical sampling of large public data sources (Wilson et al., 2022).

Following this introduction, we present the methods, then results, then we will discuss the findings and conclude. We present our findings in five parts. First, we examine the existing conditions of the homes in the study and compare them across income, including key housing characteristics and indoor temperature preferences. Next, we quantify the impact that replacing natural gas heating with heat pumps would have on household energy burden. We then examine the sensitivity of time of use utility rates on the annual energy bill impact of fuel switching. Following that, we quantify the cost savings potential of energy efficiency envelope improvements and compare it to the utility bill impact. Finally, we explore energy efficiency retrofit recommendations provided to participants during home energy audits and assess the feasibility of these improvements to mitigate the ongoing cost impact of heating electrification on the sample.

2. Methods

This study uses observed household energy use and indoor temperature data along with a reduced complexity air source heat pump coefficient-of-performance model to determine energy cost and energy burden impacts of switching to a heat pump. We gather energy retrofit recommendations and estimate upfront costs, energy cost savings, and payback from a contractor who conducted a detailed energy audit for each home. We then quantify annual utility bill impacts for fuel switching and energy retrofits using a building energy model that provides detailed sub-hourly simulations a large sample of archetypal homes that are representative of the study region and compare them to our findings for the sample.[1]

[1] See Data Availability statement for more information on how to access data that can be made available under the Institutional Review Board guidelines for human subjects research. See Supplemental Methods for additional detail on justification for model and calculation assumptions and Supplemental Figure, Tables, and Notes for detail on participant demographics, supporting findings, and literature review.

2.1. Participants

As described below, we recruited 51 participants from Wayne and Washtenaw Counties in Michigan, which encompass the Detroit and Ann Arbor metro areas. We chose Southeast Michigan for three factors that make this study applicable to global contexts including the Midwest, New England, and the Mountain West regions of the US; Northern Europe; and the United Kingdom: cold climate, predominance of natural gas for heating, and older homes.

Participant recruitment included three steps. First, we circulated an expression of interest form through local media, university email lists, and local environmental and energy justice community groups that drew more than 1300 responses. Second, we asked these respondents to complete a demographic survey to assess the presence of key factors associated with energy insecurity: race, income, disability, children, and health vulnerability (Drehobl et al., 2020; Reames, 2016; Hernández, 2016). We received 883 responses to the demographic questionnaire. Third, we identified a random sample stratified using survey answers to ensure representation across four key, binary, classes of vulnerability: has a disability, has at least one child at home, foregoes paying energy bills at least once a year, controls heating or cooling for a vulnerable occupant. These four classes correspond to 16 combinations, and we had respondents who corresponded to only 10 of them.

Next, we identified 418 survey respondents living in single family homes. We then classified the respondents into 10 categories representing the unique combinations of the key categories listed above. We calculated how many households we would need to invite to have an equal number across these categories and randomly selected that many households from each group. Where the quantity of respondents in a category was not great enough to provide an equal weighting, we invited all the respondents in the category. Ultimately, we compiled a list of 90 potential participants to whom we sent invites to join the study. Our recruitment rate was 58 %. Demographic questions and descriptive statistics can be found in Note D.3 and Table C.1. 90 respondents were asked to join the study. Demographic questions and descriptive statistics can be found in Note D.3 and Table C.1.

All households in the sample live in single family homes. 50 of the 51 households are homeowners; 1 is a renter. All homes use natural gas for heating with the exception of 1, which uses propane. The sample includes a diversity of housing vintage (i.e. common building practices) from every decade since 1900: 9 homes were built before 1940, 17 homes were built between 1940 and 1960, 12 built between 1961 and 1980, 6 built between 1981 and 2000, and 7 built after 2000.

The study sample is representative of the populations of the two counties of Southeast Michigan along two key characteristics. (1) Income: the median income (in 2022 dollars) is $57,223 for Wayne County and $84,245 for Washtenaw County (U.S. Census, 2024). The sample includes 11 households reported earning annual income <$25k, 18 earning $25–50k, 9 earning $50–75k and 13 earning >$75k. (2) Race: 54.6 % white, 38.3 % Black, and 7.1 % all other races in Wayne County and 73.9 % white, 12.4 % Black, and 13.7 % all other races in Washtenaw County (U.S. Census, 2024). The sample includes 29 % Black (n = 15), 45 % white (n = 23) and 25 % (n = 13) all other races, including one participant who prefers not to answer.

Households were provided $100 compensation.

2.2. Data collection

We obtained one year of utility data for each household, including hourly metered electricity use and daily metered gas use where available. We conducted one visit to each home, during which we installed a smart thermostat where the heating and cooling system could accommodate the product (Ecobee 3 lite) (n = 40). For homes that could not receive the smart thermostat, we set up a wi-fi connected thermo-hygrometer (Govee H5179). Both devices record data at 15-minute intervals. An accredited energy audit contractor accompanied the research team and performed an ASHRAE Level 2 energy audit at each home.

Participants provided income ranges, so we estimate energy burden based on the arithmetic midpoint, i.e., if a participant reports their income to $25k-50k, the energy cost burden for that household was calculated at the proportion of their actual annual utility bills to $37.5k. We did not apply an equivalence scale to energy expenditure and income because we observed occupancy in some homes to which the published equivalence scales would not readily apply, for example, households with adult children that may live at home for periods of time varying duration and frequency throughout the year. See Supplementary Methods for detail on energy burden calculation.

2.3. Housing quality analysis

To assess participant behavior, we estimate indoor temperature setpoints in two ways. First, we estimate the heating inflection temperature (HIT) (ambient temperature at which a household begins heating) for each home using a splitwise regression of metered daily gas use on hourly average ambient air temperature (obtained from NOAA Local Climatological Data (LCD) for the data collection period). Second, we evaluate the observed heating and cooling setpoints and the observed indoor temperature for the heating and cooling season for a subgroup that received a smart thermostat (n = 40). We calculate cooling and heating season means for setpoint temperature as well as the standard deviation for setpoint and indoor temperature using this interval data.

2.4. Heat pump cost analysis

Our energy cost analysis for switching to all-electric heat pumps from natural gas-based heating consists of three steps. See Appendix A for detailed calculation methodology and model specifications.

- *Heat load calculation. Existing furnace gas use.* To determine heating natural gas use, we first estimated the inflection point for temperature dependent gas use using a split-wise regression of heating degree hours (a measure of the intensity of the space heating needed for a given time and place) on hourly total gas use. We assumed that the slope of the piecewise linear function (found with the segmented() function in R) past this inflection point indicates heating related natural gas usage. From that, we derived the slope which is the natural gas usage per heating degree hour. We then obtained the amount of gas used during each hourly time step for heating by multiplying the slope by the difference between the outside ambient air temperature departure from the indoor heating setpoint gathered during the initial data collection period when the energy audit took place.

Deriving heat load. We multiplied the hourly gas use by the furnace efficiency to obtain the hourly heating load for each house. We obtained the hourly ambient temperatures for each home during the window of time the utility data was provided by the utility (e.g. 11/10/2020–11/11/2021) using the NOAA Local Climatological Data (LCD) Tool for the closest available weather station.

- *Heat pump model.* We calculated the heat pump hourly temperature-dependent coefficient of performance (COP) using the following equation:

$$COP_i' \times (1 - l(t_i)) = COP_i \; Tmin < t, \; i \in 8760$$

$$COP_i = 1 \; t < Tmin$$

Where:

i indexes hour;

COP' = manufacturer reported coefficient of performance using the efficiency curve (ambient temperature vs. COP) of the Mitsubishi M2i cold climate ASHP for heating;

$l()$ = defrost efficiency loss for give temperature, t (%);

t = **hourly dry bulb temperature (F)** using the NOAA LCD weather data for the same period for which had metered natural gas data for each home;

COP = observable coefficient of performance;

$T_{min} = 10°F$ reflecting ambient temperature change over point from heat pump to backup heating mode via electric resistance coil;

$<T_{min}$ **COP** $= 1$ reflecting the heating efficiency of an electric resistance coil used for backup to ensure that heating setpoints are met below the change over point.

We calculated percentage improvement in cooling energy by dividing the Mitsubishi H2i SEER rating (SEER = 17) by the on-label AC efficiency obtained from the energy audits for each home. This kind of high efficiency equipment comes with a first cost premium over a standard furnace replacement. It is therefore expensive for low- and middle-income households and is likely not affordable without a subsidy that covers most of the cost. Selecting this equipment is a conservative assumption. We then applied this factor to an average cooling energy percentage obtained from the Resstock End Use Savings Shapes (Wilson et al., 2022) to determine the annual energy cost savings.

- *Energy cost calculation.* We calculated the energy cost using a model we developed in R that takes in the hourly estimated electric and daily gas usage for the hypothetical heat pump scenario and calculates the total bill costs in the manner calculated by the utilities as published in the electricity and gas rate schedules ("DTE Electric Company Rate Book for Electric Service", 2023). For example, to calculate the annual electricity cost for each home, we apply the flat rate service charge per month, capacity and non-capacity energy charges assessed per kWh, as well as surcharges and credits. We completed this process for three electricity rates and two gas rates to test the sensitivity of our results to rates available to participants. See Figure B.7 for rate summary and Note D.5 for rate description. We do not include tariff changes from one year to the next because future rate changes are unpredictable and beyond the scope of the analysis. Changes in consumer behavior associated with changes in utility tariffs are also beyond the scope of the paper and therefore not included in the analysis. Additionally, incorporating behavior changes would not have a meaningful impact on the results because short term elasticities are low for electricity and natural gas in the US (U.S. Energy Information Administration, 2021).

2.5. Resstock

We analyzed the potential for energy efficiency to mitigate cost increase due to heat pumps by calculating energy costs derived from four modeled retrofit scenarios included in the NREL Resstock End Use Savings Shapes database (Wilson et al., 2021). We selected hourly load profiles available for a baseline case and three "upgrades" including full electrification with or without deep efficiency retrofits, and deep efficiency retrofits with no change to the HVAC systems. To these scenarios, we applied the utility rates for all sensitivity cases as described above. We then calculated the mean incremental annual energy costchange resulting from a series of these changes across a random sample of 400 homes in the database representative of Detroit, MI.

2.6. Retrofit cost analysis

The contractor recommended energy efficiency measures and provided first cost and utility cost savings estimates for the recommended work. We used the "Return on Investment and Rebate Report" prepared for each study participant to summarize the recommended energy efficiency upgrades to code the unique efficiency measures recommended across the sample.

The parameters we used for estimating the feasibility of retrofitting were economic payback in years for the package of all recommended retrofits (calculated as the first cost divided by the annual energy cost savings), the first cost of the total package, and the modeled utility cost savings for the individual measures. The values for these parameters were obtained from the retrofit reports provided to participants by the energy audit contractor. The payback parameter described above follows the US Department of Energy Methodology and Procedures for Life Cycle Cost Analysis (Code of Federal Regulations. 10 CFR Part 436 Subpart A). No discount rates are used, making this the best-case estimate of the payback period. Given our findings, the decision to use an undiscounted payback period is conservative: if a discount rate were applied, the payback period would be even longer, strengthening our argument that the retrofits are not attractive on the basis of utility bill savings. Additionally, we show the rates that participants were provided as part of their energy audit, so payback periods not inclusive of a discount rate are more representative of the data participants have to inform their decision making.

3. Results

We find that electrifying homes with heat pumps increases annual energy cost by 58 % on average (range: 11–182 %) when compared to natural gas heating and considering a flat electricity rate, higher than previous estimates. This change exacerbates already high energy burdens for low-and-moderate income (LMI) households. While we find energy retrofit opportunities that saved energy cost for every home, they came with substantial obstacles that could limit uptake. There is an average payback period of 24 years and homeowners can be left without sufficient information to act, even after a visit from a home energy auditor. Willand et al. (2020) identified this situation as the retrofit trap in their 2020 analysis of Australian home retrofit programs. It can be understood as a form of poverty trap, defined Azaiadis and Stachurski as a reinforcing mechanism that acts as barrier to adoption of techniques that can alleviate poverty (Azariadis and Stachurski, 2005). The clean energy transition is hindered by an energy poverty trap because the extensive retrofits needed to make electrification affordable are themselves too expensive for low-income households.

3.1. Housing quality vs. set-point choices

We estimate energy burden for each household by calculating the proportion of their annual combined electricity and gas cost (sourced from utility bills) to the self-reported income range. The 5 highest energy burdened households have rates ranging from 10 to 40 %. 32 % of homes have energy burdens greater than 6 %, which is considered a high energy burden and twice the national average (Drehobl et al., 2020). All these households have below-median incomes. 37 % are between 3 and 6 %. 31 % of homes have an energy burden below 3 %; all but one of these homes have incomes that exceed the local median (see Figure B.1). See Table C.1 for descriptive statistics on utility costs and energy burden. Table C.6 provides a list of self-identified household income ranges and a comparison to the area median income (AMI) by zip code.

Not all homes in our sample were of the same age and quality. The homes were on average 60 years old and built in an era during which Michigan did not have energy efficient building codes.[2] These codes were adopted for the first time 1977 when ASHRAE 90–1975 was adopted state-wide ("US Dept. of Energy Building Energy Codes Program", 2024). 13 homes (5 in the <$25k income group and 8 in the $25–50k group) had been retrofit by Habitat for Humanity of the Huron Valley (Habitat) resulting in higher quality for their age. Improvements had been made 1–10 years prior to participating in this study.

Homes retrofit by Habitat perform consistently better than market rate homes in the sample [Fig. 1]. To understand the impact of these

[2] They were adopted for the first time 1977 when ASHRAE 90-1975 was adopted state-wide. (US Dept. of Energy Building Energy Codes Program, www.energycodes.gov/status/states/michigan).

retrofits on overall home energy efficiency, we examine the difference between trends of annual energy use per unit floor area (or energy use intensity) and per occupant across income in market rate homes compared to the Habitat homes. When treating self-reported income categories as an ordered set (<$25k, $25–50k, $50–75k, and >$75k) in a least squares regression of energy use intensity (EUI) per occupant on income, we find a significant downward trend (p-value=0.048) for market-rate homes, indicating that low-income households either live in less energy efficient homes or there is significantly different behavior across income levels.

The latter explanation would suggest, for example, that lower-income households start to use heating at higher ambient temperatures and cooling at lower ambient temperatures. Cong et al. provide evidence to the contrary. They find that lower-income families wait for ambient temperatures to rise higher before turning on air conditioning compared to those with higher incomes (Cong et al., 2022). This would imply that low-income families use less energy, a seeming contradiction of our results. However, we believe that there is no contradiction, since the Cong et al. results are not directly comparable to ours for two reasons. First, we report energy use per square foot per occupant, which Cong et al. do not observe. Second, Cong et al. have studied air conditioning, whereas energy use in our sample is dominated by heating. Huang et al. (2023) do find evidence that low-income households start to heat earlier in the season and heat for more months of the year than higher-income households. However, these results are also not comparable to ours since there is no normalization by area or occupancy. We estimate the heating inflection temperature (HIT), or the outdoor temperature at which each household turns on the heat because in every case heating constitutes the highest proportional energy expenditure (>60 %). To estimate the HIT, we calculate a linear splitwise regression of metered daily gas use on ambient air temperature. We find no significant trend in HIT across income (see Figure B.2). Combined, our findings and those of Huang et al. (2023) suggest that behavior-driven energy use patterns are unlikely to explain the higher energy use of low-income homes.

Observed heating and cooling setpoints—read from participants' smart thermostats—likewise reveal that lower income households do not on average choose higher setpoints in winter or lower setpoints in summer [Fig. 2a]. We do observe greater variance in the set points that households in the lowest income group (<$25k) choose [Fig. 2b], as well as in the indoor temperatures that they experience [Fig. 2c]. This suggests that, even though they have higher energy use intensity, these households are actively trying to manage their energy use and comfort by manipulating their set points. This provides evidence that the higher EUI is in fact due to poorer building envelopes and not because lower-income households are choosing consistently different setpoint temperatures.

We look at housing characteristics to explore whether the homes occupied by low-income households are in fact less efficient. Blower door testing conducted at each home provides an empirical measure of efficiency by measuring air infiltration. Low infiltration signifies high efficiency. We find that the homes retrofit by Habitat have better performance than market-rate homes in the sample. The median measured air infiltration rate of Habitat homes is almost half that of their counterparts (4.2 ACH 50 and 7.7 ACH 50, respectively) with less variability (range: 2.9–5.9; IQR = 3.4–5.3 and range: 3.2–17.5; IQR = 5.8–10.9, respectively). Applying the same regression method described above, after excluding Habitat homes, we find a significant downward trend (p-value = 0.023) for market-rate homes, indicating that the lower-income homes are indeed less efficient (Figure B.3).

3.2. Energy burden

For the 51 houses in our sample, we calculate the electricity loads that would result from replacing natural gas furnaces with air source heat pumps for space heating (see Supplementary Methodology for more detail on reduced complexity model and load derivation) and apply the most prevalent gas and electric utility rates across the sample to determine the energy cost change associated with this replacement. We calculate change in annual energy bills and energy cost burden which refers the difference in energy expenditures and percentage of income spent on utilities, respectively, between the baseline scenario and the heat pump scenario. 41/51 households were on a standard time-invariant rate, which will be discontinued as of May 2023. 10 had elected different rate structures, which include time-of-use rates, interruptible cooling rates, and specialty rates designed for low-income households. We find that switching to a heat pump would increase annual utility bills for every household in the sample, and that the cost goes up by $1154 on average (see Table C.3).

Our results show variability in median cost change across income and a disproportionate concentration of high energy burden increase below median income (<$25k and $25–50k). The median cost increase for below median income households is $801 ($n = 28$), constituting a 37 % utility spending increase on average. There is a 49 % utility spending increase for above median income households on average ($n = 22$) [Fig. 3a-1]. Even though the median cost increase is nominally lower for

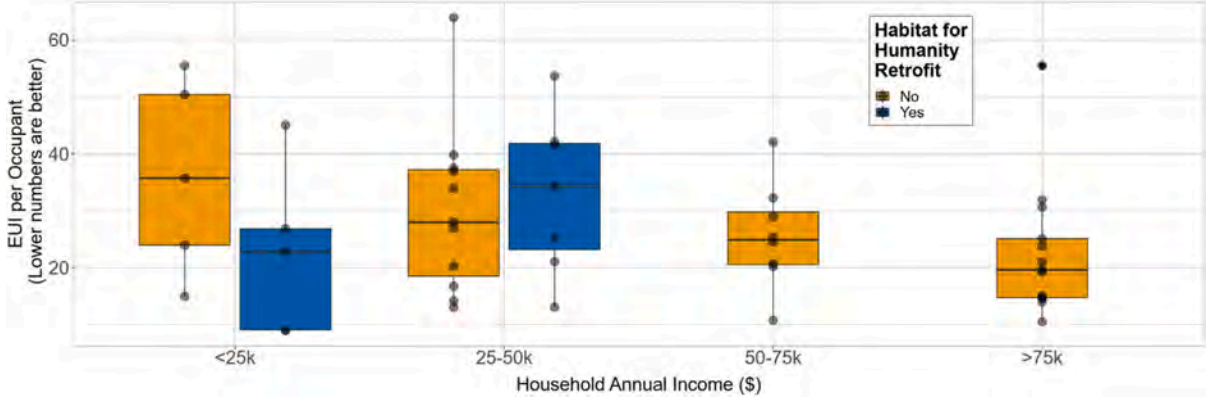

Fig. 1. Energy use intensity per occupancy by income group. Annual energy use per floor area divided by the number of occupants is shown here. The x-axis represents four income categories to which participants were assigned given the income range they provided. Each box plot shows the median (middle line), first and third quantiles (lower and upper box bounds), and minima and maxima (whiskers). The blue boxes represent homes that have been retrofit by habitat for humanity, which perform better than market rate homes in the sample (represented by oranges boxes) for homes earning less than $25k. Each dot represents one household. Using a non-linear least squares regression, we find a significant downward trend (p-value = 0.048) among market rate homes, indicating that those with lower incomes live in less efficient homes.

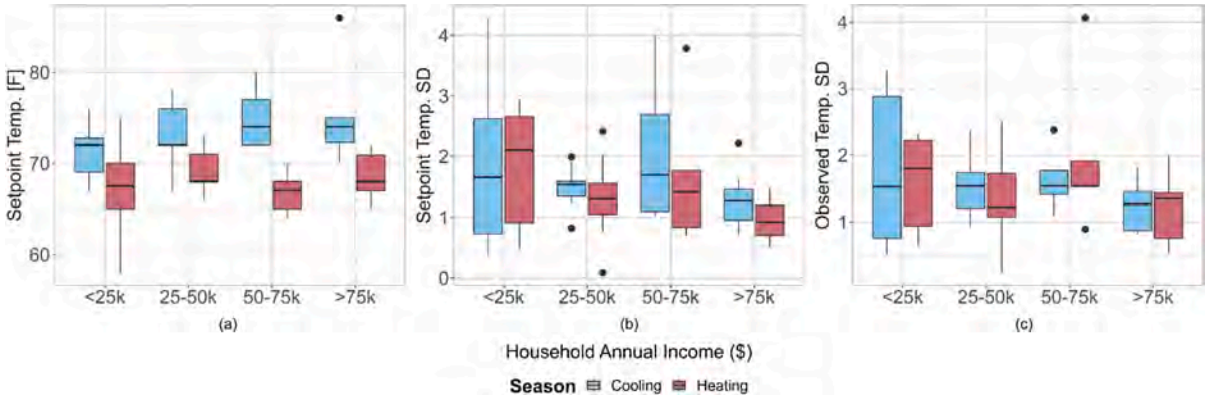

Fig. 2. a-b-c: Thermostat setpoint and observed indoor temperature by income. Observed heating and cooling setpoints (a), setpoint standard deviation (b), and indoor temperature standard deviation (c) on smart thermostats for each home.

below median income households, their energy burden increase is 4 times higher on average than those at or above median income [Fig. 3b-1]. Additionally, all households earning median income ($50–75k) and above (>$75k) - which currently have a median energy burden of 2.6 % – would experience a median change in energy burden of greater than 1 percentage point, indicating that energy burden could become a concern for households which are currently energy secure.

3.3. Time of use electricity rates

We examine the impact of two time-of-use rates available to all customers in the study region on the annual increased utility costs and energy burdens of the sample for a hypothetical conversion to heat humps. Switching to the standard time-of-use rate (DTE no. D1.11) ("DTE Electric Company Rate Book for Electric Service", 2023) reduces the mean cost increase for the sample by $120 per year from $1154 to $1034 (see Fig 3a-2) relative to a flat rate. Under this rate, the median

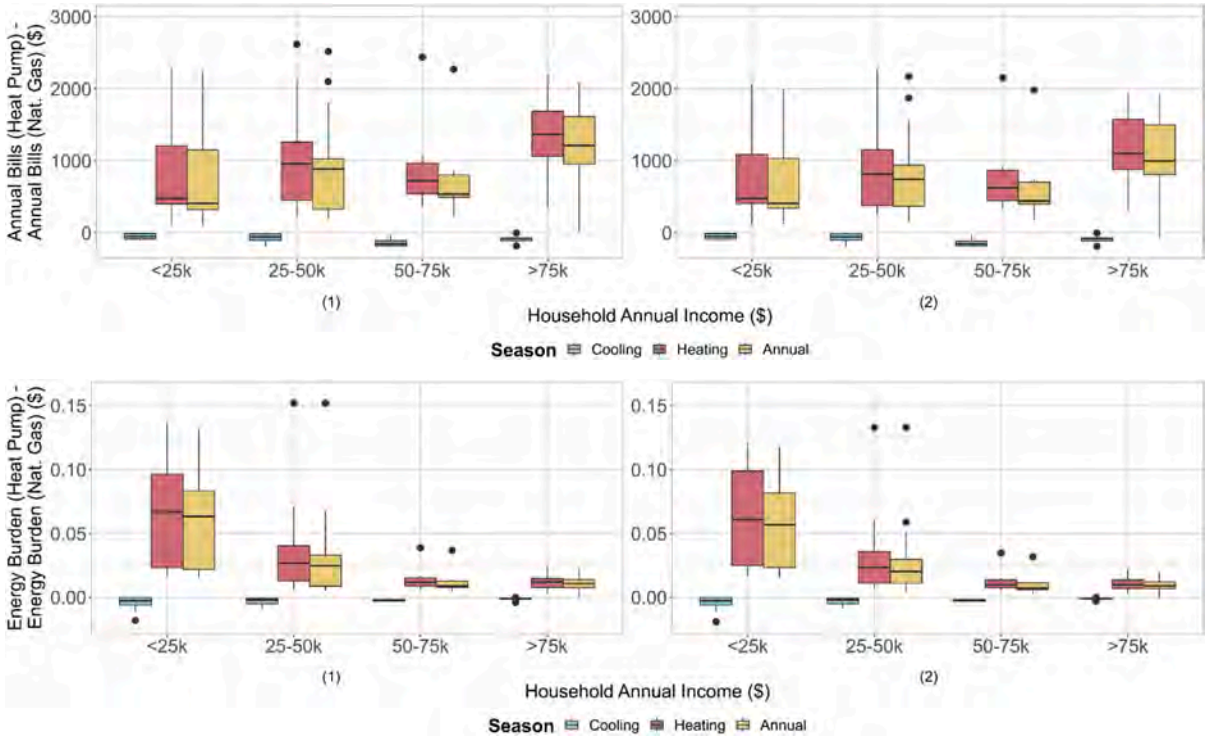

Fig. 3. a: Change in annual energy bills for switching to a heat pump from natural gas heating by income. The x-axis represents four income categories to which participants were assigned given the income range they provided. Dot represents outliers. Each box plot shows the median cost increase (middle line), first and third quantiles (lower and upper box bounds), and minima and maxima of change in utility cost change for (1) standard flat electricity rate and 2022 natural gas cost; (2) standard time-of-use electricity rate and 2022 natural gas cost.
b: Change in energy burden for switching to a heat pump from natural gas heating by income. The x-axis represents four income categories to which participants were assigned given the income range they provided. Dot represents outliers. Each box plot shows the median energy burden increase (middle line), first and third quantiles (lower and upper box bounds), and minima and maxima of change in energy burden change for (1) standard flat electricity rate and 2022 natural gas cost; (2) standard time-of-use electricity rate and 2022 natural gas cost.

utility cost change due to heat pumps is lower for every income category. The effect of this lower cost change is minimal for energy burden, reducing the rate by less than 1 percentage point for each category [Fig 3b-2].

By comparison, relative to a flat rate, the optional time-of-use rate (DTE no. D1.2) (DTE Electric Company Rate Book for Electric Service, 2023) would worsen the increase in annual utility cost for switching to a heat pump for all income groups. Switching to D1.2 increases the mean cost increase for the sample by $623 per year to $1777 (see Figure B.4). This rate nearly doubles the median energy burden changes for all income groups earning less than $75k (see Figure B.5). The D1.2 rate had a higher cost per kWh at peak times and a peak window two hours longer than the D1.11 rate. These rates impacted each household differently given the variety of occupants, schedules, housing vintage across the sample. For instance, those who saw the greatest cost increase with the standard time-of-use rate had the oldest, least efficient AC units in the sample and used their cooling systems during the peak window, whereas, in reality, the switch to a heat pump would include a new, more efficient AC.

While the gas commodity prices have risen dramatically from 2021 to 2023, the delivered price of natural gas for residential customers has in fact been modest and does not affect the results. See Figures B.4 and B.5 for a comparison of annual bill and energy burden changes with 2021 and 2023 gas rates. See Table C.2 for a detailed comparison of all of the electricity and gas rates available to DTE customers as of 2023 and their impact on baseline household energy use.

3.4. Energy retrofit model

Energy retrofits are a possible strategy to mitigate this increase in bills. Since we do not have empirical estimates of cost savings potential of envelope improvements to mitigate the cost increase of heating electrification, we first model the corresponding energy uses using the NREL ResStock End Use Savings Shapes (Wilson et al., 2022). We randomly sample 400 Michigan homes heated with natural gas from the database and examine four scenarios: baseline envelope with natural gas heating, envelope upgrade, heat pump upgrade, and combined heat pump and envelope upgrade. To then convert the energy uses to cost, we apply the electricity and gas rates experienced by 41/51 of our study participants to the hourly electricity and gas loads to estimate the relative cost impact of retrofits for the natural gas scenario and the heat pump scenario.

We find that transitioning to a heat pump without energy retrofits results in a mean utility cost increase of 26 % over the baseline. Adding a comprehensive envelope retrofit improvement mitigates this cost premium and drives utility costs back to what they were with natural gas heating with the existing envelope. Energy efficiency retrofits alone reduce bills by 11 % compared to the baseline condition [Fig. 4].

See Note D.1 for a comparison of the modeled results to the estimates calculated using observed data from the field study, including a breakdown of model findings by house vintage (Figure B.6).

3.5. Contractor retrofit recommendations

Our results suggest that, with energy retrofits, most homes would not experience an increase in utility bills relative to the status quo if they shifted to heat pumps. Based on REM/Rate (REM/Rate 2024), commonly used software, our contractor recommended a different combination of ten individual retrofit measures for the homes in our sample and these upgrades are expensive with long payback periods. The most commonly recommended measure is air sealing, an intervention in which joints are sealed to reduce air infiltration. We classify building envelope upgrades as simple if they can be completed by one contractor (e.g., spraying cellulose in the attic) and complex otherwise (e.g., foam injection into drywall). Upgrades to the HVAC system are in a separate category, as are upgrades to other appliances (e.g., fridges) (see Figure B.8). The median retrofit package costs are about 10 % of household income. ($3250 for <$25k; $4700 for $24–50k; $10,300 for $50–75k; $7000 for >$75k) (see Figure B.9). 14 households in the lowest three income groups are faced with total package costs of more than 20 % of their income. The median payback period across the sample is 24 years, with a large variance across the income groups (see Figure B.10).

Upfront cost and simple payback estimates for retrofits match previous studies. Fowlie et al. (2018) use empirical estimates for actual energy savings across the Michigan WAP and find internal rates of return (IRR) at −10.6 % (10 year), −2.3 % (16 year), and 0.21 % (20 year). We find even lower IRR for the recommended retrofits by the energy

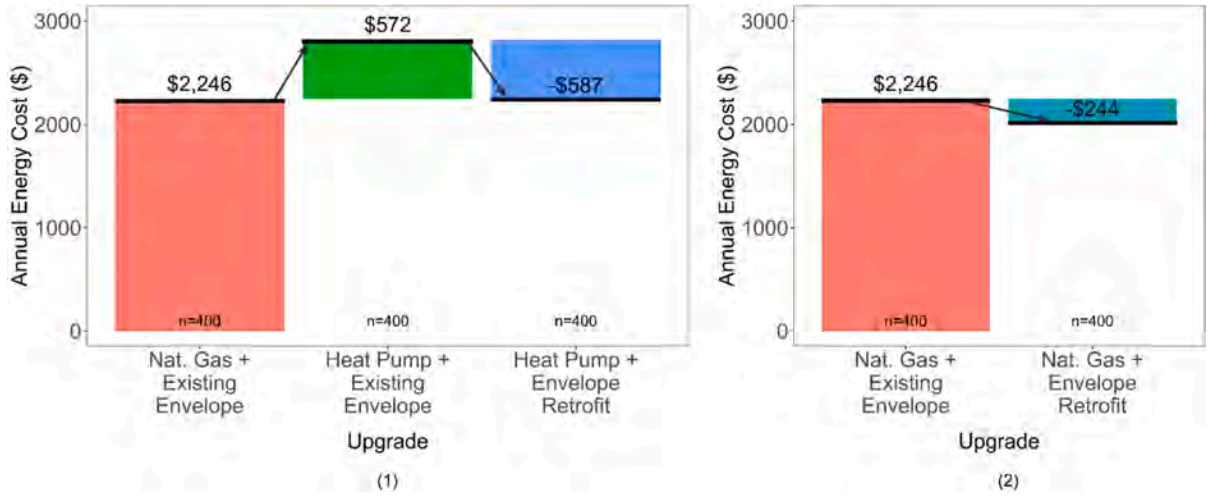

Fig. 4. Modeled mean annual energy cost impact of heating electrification and envelope improvements. (1) The baseline case (natural gas heating with existing envelope) represented in red is compared to two upgrades: heat pump with efficient envelope retrofit (green) and heat pump without envelope improvements (blue). (2) The baseline case (natural gas heating with existing envelope) represented in red is compared natural gas heating with efficient envelope retrofit (teal). Means represent 400 randomly sampled homes from the ResStock end use load profile database that use natural gas in Michigan. Using a Kruskall–Wallace test, we find a significant difference between the medians of the utility costs in each upgrade category (p-value < 0.01). We test the null hypothesis that the medians were the same using a pairwise with the Bonferroni adjustment and similarly find significant differences for each comparison.

assessment contractor: −16.1 % (10 year), −5.3 % (16 year), and 2.2 % (20 year). Less et al. (Less et al., 2021) estimate an archetypical retrofit package for a single family house that includes the most common retrofit recommendations in our sample (attic floor insulation, air sealing, foundation floor insulation) based on actual US construction costs at $7825 (see Note D.2 for measure cost calculation). The mean upgrade package cost estimated by the energy audit contractor in our sample is $7628 and the median is $5900 (see Figure B.9). Since the package described by Less et al. excludes system or appliance measures, we surmise that it is likely our contractor's costs are underestimates. Realized project costs could be higher, and payback periods longer.

There is no clear pattern about what measures are most cost-effective. The results show a large range of annual cost savings available from the recommended retrofit packages, with annual utility bill savings ranging from $26 to $730 [Fig. 5a]. We find that air sealing, which was recommended to all households, provides a payback range of 3.7 to 144 years [Fig. 5b] and attic insulation alone provides a payback range of 20 to 259 years (see Note D.2 for measure cost calculation). The high-end estimates that reflect payback periods much higher than seen in the literature are due a sample-specific scenario in which 25 % of the homes in the study received energy efficiency retrofits before the study period. For these homes, which were already high performing, the contractor recommended improvements to existing conditions (such as attic insulation and air sealing), which resulted in marginal energy savings and therefore long payback periods.

4. Discussion

We explored the drivers of energy inefficiency, explored the economic impact of replacing natural gas furnaces with heat pumps by income, assessed a range of energy retrofit measures that could support utility cost reduction in the 51 Michigan households we studied, and compared this impact to estimates from a national model. Heat pumps raise energy cost and energy burden disproportionately for low-income households. The median utility cost increase for switching to a heat pump is lowest for low-income households because they use the least amount of energy. This finding is suggestive of an efficiency paradox (Goldstein et al., 2022) where the lowest consuming households live in the least efficient homes, indicating that they are likely not using enough energy to meet their health, safety, and comfort needs. Yet, the increase in energy burden is disproportionately higher for low-income groups because even though their cost increase is nominally the smallest, it is a greater percentage of their annual income. Our results show that adopting heat pumps results in a fmedian energy burden increase of 75 % and 54 % for both income groups earning below AMI (<$25k and $25–50k, respectively). Given that households below median income have a 6 % median energy burden on their existing natural gas heating systems, such increases would severely worsen existing energy insecurity, for instance increasing risk of poor health (Reames et al., 2021) and coping behaviors like trading off paying utility for paying for rent or food (Hernández, 2016), or the underconsumption of energy in household who struggle to pay their bills (Meyer et al., 2018; Barrella et al., 2022; Faiella and Lavecchia, 2021; Antepara et al., 2020).

Policymakers should act to help lower the operating costs of heat pumps compared to natural gas for low-income households in cold climates. This can be done in three ways. First, government-sponsored initiatives to advance more efficient heat pump technology like the U.S. Department of Energy Residential Cold Climate Heat Pump Challenge are essential to improve energy bill affordability of fuel switching. More efficient heat pumps reduce the utility cost premium over natural gas furnaces.

Second, state regulators should exercise a more robust scrutiny of utility company returns and create more opportunities to improve customer outcomes in the rate making process. For example, the Michigan Public Service Commission recently ruled in a disputed rate case in the study region that resulted in allocations for energy retrofits in historically underserved areas due to intervening efforts from customer groups not typically represented in rate making like community

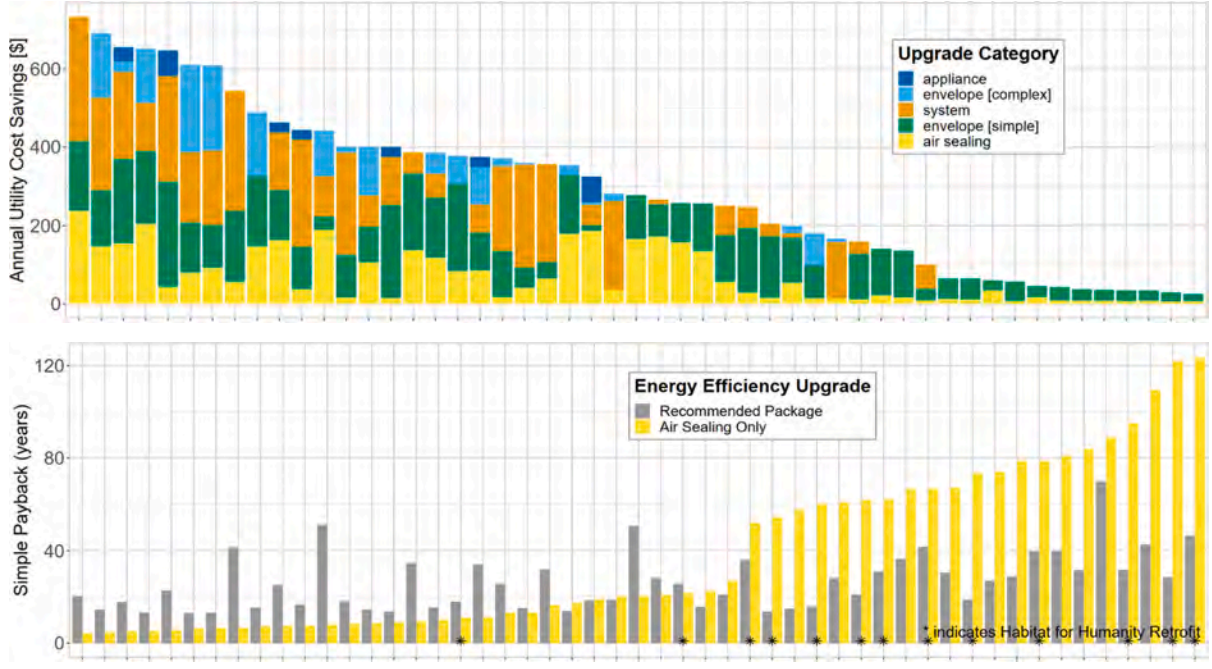

Fig. 5. a: Annual utility cost savings for retrofit packages by household. Colors represent categories we develop to indicate the relative cost and difficulty of adopting the recommendation. There is no clear pattern for which energy retrofits provide the best payback.
b: Simple payback for the recommended package and air sealing by household. Gray bars represent the payback for the full retrofit package recommended for each home. Corresponding yellow bars represent the air sealing payback period for that home. Star indicates houses that have been retrofit by habitat for humanity.

advocates and municipal governments (Hon et al., 2023). A high ratio of per-unit electricity to gas rates makes heat pumps less attractive than natural gas furnaces.

Third, states should consider implementing percentage of income payment plans (PIPP) that place a cap on energy expenditures relative to household income. These programs can be paired with federal- and state-funded retrofit programs to simultaneously improve the building stock and mitigate energy poverty. Capping household utility costs insulates low-income households from increase in bills.

Local factors exacerbate the economic penalty for household heating electrification described in this study and pose additional barriers to change not found in other regions. In our study sample, the average electricity cost is $0.18 per kWh and gas costs $0.8 per 100 cubic feet, or $0.03 per kWh. Per unit energy, electricity is therefore 5 times more expensive than gas, which is a large-enough difference that the higher efficiency of heat pumps is unable to compensate for it. (See Table C.4 for energy burden changes by income). Our results show that under these circumstances, energy cost increases for heating electrification could be disruptive even for households earning twice the median income.

Low-income households will need expanded and flexible financial assistance to retrofit their homes to prepare them for electrification. The subset (25 %) of homes that received deep energy retrofits prior to the data collection period had consistently more efficient air sealing and attic insulation than the market-rate homes. Retrofits to improve the performance of these characteristics were the most frequently recommended to study participants by the contractor, but we found they had a large range in payback period. There was no clear best choice investment that would provide either the greatest utility savings or the best payback, making it difficult for policymakers to make broadly-applicable recommendations for energy efficiency retrofits.

The group of very low earners (<$25k) with low energy burdens living in highly efficient homes were the same households that experienced the lowest energy burden increase due to heat pumps. This demonstrates the value of energy efficiency improvements in buffering households from the impact of utility cost rise due to electrification. However, the retrofits that provide the remedy are expensive. Our findings suggest that actual upfront costs for recommended retrofits in homes that have not been renovated far exceeded the $7700 cap for the Weatherization Assistance Program. Additionally, the payback periods in many cases were so high the projects would not qualify for the program, which requires a 1:1 saving-to-investment (SIR) ratio without consideration of discount rates. Current programs need to be expanded to cover the cost of expensive upgrades, and to be made available to more homes.

5. Conclusions

Policy action is needed to make heating electrification viable. The economics of electrification are adverse for the existing housing stock in cold climates. Our findings suggest that heat pumps are not a feasible economic alternative for households currently using natural gas, unless governments offset energy cost premiums through public funding. Some of the policy discussion around heat pumps does not acknowledge this (U.S. Department of Energy, 2023; Rewiring America, 2021; Fathollahzadeh et al., 2022). Such an investment can be justified on the basis of equity and by internalizing the social cost of carbon, current estimates of which are ~$180 per ton CO2 (U.S. Environmental Protection Agency, 2022; Rennert et al., 2022).

Coupling heating electrification with retrofits in existing homes with natural gas heating can limit utility cost increases and reduce a key barrier to heat pump adoption. At the same time, our study shows that even after a visit from a home energy auditor, homeowners can be left without sufficient information to act. The reports they are provided could be more useful in supporting investment decisions by providing a marginal abatement curve specific to each house, where the payback period of each measure is plotted against the cumulative cost of all the recommended measures. The homeowner can decide the most they are willing to spend, and the curve would show them all the fastest-payback measures that can be implemented for that amount.

The impact of rate structures should be analyzed based on empirical data from the rate base. Time-of-use rate design for electricity determines the cost increase for switching to heat pumps. We estimate that one rate (D1.11) reduced the increase in bills by 10 % compared to the flat rate (D1), while the other (D1.2) further elevated the average cost increase by 56 %. Modeled results using ResStock show the opposite, where the D1.11 rate is usually no worse than the flat rate (see Figure B.7 for utility rate comparison). Using empirical energy use data in utility rate design to understand how proposed rates affect households across the income spectrum and across housing quality given future adoption of heat pumps could help mitigate energy insecurity and promote greater access to heat pump adoption among natural gas users.

While our focus on Michigan allows us to understand the cost dynamics for electrification in a cold climate with high prevalence of natural gas use, limitations of our study include the small sample size and the limited regional scope. Additionally, we were unable to incorporate homeowner attitudes regarding converting their natural gas heating systems to electric heat pump systems. Future work will investigate these perceptions, examining the factors that influence decision making for residential electrification and further examining potential barriers to equitable adoption of heat pumps across income.

ABSTRACT

As the atmospheric concentration of CO_2 steadily increases and the world grapples with the pressing challenges of global warming, international research communities are actively exploring inventive technologies to combat the adverse effects of elevated CO_2 levels. An important challenge in this context is to extract CO_2 directly from the atmosphere. Consequently, capturing the last from seawater is crucial due to its impact on the delicate balance of marine ecosystems and the potential consequences for global climate regulation. While DAC and DOC show potential towards combating climate change, challenges including high operational costs and the need for further technological advancements persist. This paper critically discusses the status, challenges, and scalability of DAC and DOC at pilot or industrial scale. Key challenges include capital and operational costs, energy demands, and integrating green energy sources to reduce environmental impact. The review emphasizes on techno-economical benchmarking analyses to evaluate feasibility for large-scale deployment and their effectiveness in mitigating CO_2 emissions and acting as tools towards delocalized CO_2 production.

1. Introduction

As defined within the Paris agreements and the Global Climate Actions, announced at the COP28 conference hosted by the United Nations in 2023, global temperature rise should not exceed 1.5 °C compared to pre-industrial temperatures to limit the impact of climate change [1]. Human dependence on fossil fuels is still dominant and the transition to green energy production or decarbonization solutions ongoing [2]. In order to mitigate past and current emissions, the capture over 10 gigatons of greenhouse gases, primarily carbon dioxide (CO_2) annually from the air by 2050 to remain below this 1.5 °C threshold [3]. Negative emissions are essential alongside point source capture because they offer a means to actively remove carbon dioxide from the atmosphere, helping to offset emissions that are difficult to eliminate entirely. Direct Air Capture (DAC) and Direct Ocean Capture (DOC) play crucial roles within the broader spectrum of negative emissions technologies, complementing approaches such as afforestation, Bioenergy with Carbon Capture and Storage (BECCS), and Ocean Alkalinity Enhancement (OAE) [8,9]. While point source capture targets specific emission points, DAC and DOC provide additional avenues for carbon removal on a larger scale, contributing to overall efforts to combat climate change. Integrating these various technologies allows for a more comprehensive approach to achieving negative emissions goals and mitigating the impacts of carbon dioxide accumulation in the atmosphere [9].

Direct Air Capture (DAC) is a set of technologies that involves extracting CO_2 directly from the atmosphere [4]. DAC has been demonstrated at laboratory scale and pre-industrial scale and typically employs absorption- or adsorption-based processes to strip CO_2 molecules from the atmosphere. Once captured, the CO_2 must be either utilized for industrial processes, stored in tanks/reservoirs underground, or

converted into valuable products [5]. The increased global interest in DAC technologies has been encouraged through various new tax credits and policies worldwide, and a total of 18 DAC plants capturing more than 0.01 Million tons of CO_2 each year are as of 2023 operating globally [6]. Although a promising effort, these plants have an average capacity of 10,000 tCO_2 captured/year, only representing less than 0.1 % of the target CO_2 capture capacity required by 2050 to quench temperature increase [6]. DAC unfortunately remains financially prohibitive with current costs (2023) on the order of US$ 600 to 1,000/ton of CO_2 captured depending on the technology used, plant configuration, and the domestic cost of energy [7]. DAC technologies and efficiency must be improved to reach a target of $\leq$ US$ 100/ton to support market acceptance and field deployment [6].

Another route to capture CO_2 from environmental ecosystems is to strip CO_2 from the oceans [8]. Direct Ocean Capture (DOC) involves the removal of CO_2 from saline water and can be deployed either offshore or on the coastline [8]. The oceans absorb about 27 % of the total atmospheric CO_2 emissions yearly and maintain an equilibrium with that present in the atmosphere by naturally converting CO_2 to bicarbonate and carbonate ions. However, the increases in atmospheric CO_2 concentration is leading to increasingly steady acidification of all fresh and salty water bodies [9]. While the concentration of CO_2 in the atmosphere increased from ~345 ppm in 1985 to ~415 ppm in 2020 (recorded in Hawaii) [10], the pH of seawater has decreased over the same period from 8.15 in 1985 to 8.05 in 2020 (recorded in Hawaii) [11]. DOC application as a tool for carbon capture may therefore also support environmental efforts to reverse the ocean acidification process in high-risk niches and limit the impact on coral and fish communities. Many of such species are particularly sensitive to changes in pH, and further major shifts would directly affect the stability of the shells and exoskeletons of such micro-organisms [12].

Both DAC and DOC are supported by ongoing research and development, and their effectiveness, feasibility, and potential risks are subjects of scientific investigation and ethical considerations. Review papers and studies about DAC technologies used by the industry, along with future potential, life cycle assessments and the economic viability of their global application [13] have been developed whole DAC's techno-economic impact and scaling-up issues were explored providing a novel overview for its commercialization [14] in another assessment. A high-level discussion of the current DAC status and pillars of technology, as well as upcoming new projects, was introduced also [15], while current DAC plants were reviewed and compared techno-economically to evaluate future implementation between 2020 and 2050, and break-even point in terms of deployment compared to point source carbon capture systems [16]. A recent review focused on the prominent industrial DAC developers such as Climeworks plants in Hinwil and Hellisheidi and their carbon capture methodologies for cost-efficiency in CO2 capture per metric ton. Elaborate cost assessments on the selection of energy operations and the requisite process energy demands were presented. Verification of net negative emissions following carbon footprint reduction in operational plants, coupled with proposals to mitigate current DAC expenses was discussed, while highlighting the future strategies promoting a composite approach comprising private investments, governmental initiatives, corporate pledges to achieve net zero emissions, and backing from oil enterprises to enhance worldwide carbon capture capacity [17]. Another work presented mostly the LCAs of DAC processes and drawing from the outcomes of a LCA, the paper delved into the CO2 capture and mitigation capabilities of the DAC-U system, particularly emphasizing its applicability in household settings, while also scrutinizing its acceptance potential in Japan [18]. Very limited analysis have been performed on scalable DOC solutions, with only a focus on electrochemical ocean capture and electrochemical hydrogen looping (EHL) capturing efficiency [19].

In this review paper, the status of DAC and DOC particularly developed at pilot or full industrial scale is presented and critically discussed. Key challenges related to the pillars of CO_2 capture include the capital and operational costs, the energy demand, and the ability to integrate green energy sources to reduce the environmental footprint of the technologies. The focus of the review lies primarily on assessing the scalability and maturity of the technologies and establishing critical comparisons. Technological and economical benchmarking analyses are performed to evaluate the feasibility of large-scale deployment and the relevance to mitigate CO_2 emissions. A pertinent comparison between both DAC and DOC, from a deployment and scalability point of view, is also made to support an assessment of the technologies maturity and likely impact to mitigate emissions or support local production of CO_2.

2. DAC scaled-up technologies

DAC was first introduced by Klaus Lackner, a chemical engineer at Arizona State University, in 1999 [17]. DAC facilities, either permanent or mobile, are becoming increasingly popular as ways to tackle global warming and innovative solutions evaluating the performance of different sorbents/materials, processes, and designs are currently being developed [6]. As of 2023, 18 DAC plants, having a capacity of at least 1 ton CO_2 captured/year, are operational worldwide. The locations of these plants based on publically available information, are presented in Fig. 1. The majority of these sites are located in either North America or Europe.

The objective of this section is to discuss the technical and commercial maturity of commercial DAC systems. Scaled-up technologies, which have been commercialized and adopted by DAC companies will be discussed and critically assesed in terms of performance and energy requirements, as well as based on life cycle and techno-economic assessments.

2.1. Climeworks, Switzerland

Climeworks is a Swiss company, founded in 2009, that specializes in DAC technology [18]. Climeworks built in 2017 the world's first commercial DAC plant, named Capricorn, in Hinwil, Switzerland with 18 CO_2 collectors and a capturing capacity > 100 tons of CO_2/year [19]. Also in 2017, the Arctic fox facility was launched by Climeworks, combining DAC with underground CO_2 storage with a capturing capacity of up to 50 tons of CO_2/year [20]. Based on the previous plant outcomes, Climeworks was able to move into large-scale DAC by launching the Orca plant in 2021 which consists of 8 collectors, the current largest and first operational plant located in Hellisheidi, Iceland with a capturing capacity of 4,000 tons of CO_2/year [21] (Table 1, Entry 1). As an expansion of Orca, Climeworks is currently constructing the largest DAC and storage plant (Mammoth plant) in Hellisheidi, which will be designed to capture up to 36,000 tons of CO_2 annually and is planned to be operational by the middle of 2025 [22].

Climworks' technology is based on packed-bed amine functionalized adsorbents, through a cyclic process called temperature-vacuum swing adsorption (TVSA), wherby capture is performed at atmospheric conditions while regeneration is achieved at 100 °C under vacuum [23]. As depicted in Fig. 2a, ambient air flows into the collector, passing through the adsorbent to capture CO2 until it reaches maximum capacity. Once this capacity is reached, the inlet airflow is halted to initiate the desorption process. In order to desorb CO_2, heat must be delivered to the CO_2 collector at 100 °C leading to CO_2 being released from the adsorbent, with a negative vacuum pressure used as driving force [23]. Water vapour present in the captured gas stream is removed by passing a condenser prior to a separator to produce > 99.9 % pure stream of CO_2 at a pressure slightly over 1 atm and ambient temperature. A typical cycle for the batch process takes 4–6 h [24] to be completed with the majority of the duty cycle assisted by geothermal energy, as for the Artic fox and Orca plants, or from waste heat, for the Capricorn plant.

Climeworks suggests six different types of adsorbent materials for industrial applications including amine on silica, amine on alumina, amine on cellulose, two carbonate on silica-based adsorbents, and

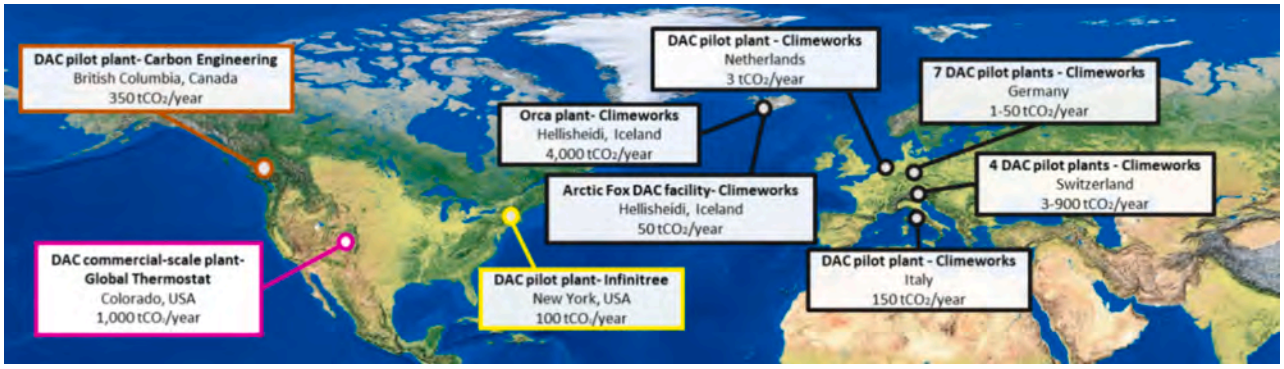

Fig. 1. Map of operational DAC plants worldwide with disclosed locations. 15 of the plants owned and managed by Climeworks are distributed around Europe. Two DAC plants are in USA; one belongs to Infinitree and the other to Global Thermostat. One DAC pilot plant in Canada owned by Carbon Engineering.

anionic resin, although specific detailed specifications are not publicly disclosed [24]. For the six adsorbents considered, the carbon footprint varies between 10 and 46 g of CO_2 emitted per 1 kg of CO_2 captured (Fig. 3(a). The production phase of the adsorbent contributes 60–91 % to the total carbon footprint of the adsorbent, which is greater than the end-of-life contribution. Fig. 3a shows that amine-functionalized alumina, potassium carbonate on silica, and potassium carbonate on activated carbon have the lowest carbon footprint. As a result of the considerable uncertainty associated with the life-cycle inventories (LCIs) of the adsorbents at the onset of their development, differences in their carbon footprints are considered minor [24]. However, Climeworks uses currently the following 2 amine functionalized chemisorbents in its processes: *(1)* SI-AEATPMS ([N-(2-aminoethyl)-3-aminopropyl]trimethoxysilane (AEATPMS) grafted on silica gel) and *(2)* APDES-NFC-FD (3-aminopropylmethyldiethoxysilane (APDES) on Nano fibrillated cellulose (NFC)) [25]. The latter is the one used in the Orca plant [25]. Other life cycle assessment (LCA) done on several DAC adsorbents showed that the production of 1 kg of SI-AEATPMS has the lowest carbon footprint equal to 4.12 kg CO_2/ kg adsorbent produced, thus the lowest environmental impact [26]. However, for the cradle-to-gate system, APDES-NFC-FD was the only one in the study that achieved an overall negative CO_2 emissions factor of − 116 kg CO_2 emitted/ton CO_2 captured [26]. In the 2nd place, SI-AEATPMS achieved an emissions factor of 625 kg CO_2 emitted/ton of CO_2 captured [26].

The two DAC plants in Hellisheidi and Hinwil were found to capture 93.1 v/v % and 85.4 v/v % of inlet atmospheric CO_2, respectively. The pilot in Hinwil, connected to a local waste incineration plant to utilize waste heat as a source of power, was used as a demonstration, to enable the development of 8-collector DAC, while the Orca plant in 2021 is located in Hellisheidi, Iceland, with a maximum capture capacity of 4,000 tons of CO_2/year [18]. Each collector in Orca is able to capture approximately 500 tons of CO_2/year. The capturing capacity of one collector is equivalent to about 20,000 trees' annual capacity. The Orca plant uses geothermal energy as a thermal energy source [27]. It requires 200–300 kWh/ton of CO_2 captured primarily consumed by the fans and control systems as well as an additional 1,500–2,000 kWh of thermal energy supply per ton of CO_2 captured for the regeneration of the adsorbent [15].

A LCA on DAC using Climeworks' technology stated it would require 3,683 DAC plants with an annual capacity of 100 ktons of CO_2 per plant to capture 1 % of the global annual CO_2 emissions equivalent in 2019 without any material or energy constraints [24]. Corresponding demand for materials (except adsorbent) and energy have low shares (below 0.1 %) of their global. The LCA is utilizing data from the plants in Hinwil and Hellisheidi, Switzerland, and considers the TVSA-based DAC system. Using an energy source with the least possible carbon footprint would enhance the benefit of DAC in climate change mitigation, in addition to the type of adsorbent as discussed before, as well as plant construction. At Hellisheidi, the DAC uses geothermal energy, while at Hinwil, it uses municipal waste incineration as a source of energy. In a worst-case scenario without metal recycling, the construction of a DAC plant with a capacity of 4,000 tons of CO_2 captured per year would emit only 15 g of CO_2 per kilogram of CO_2 captured (Fig. 3(b). In a best-case scenario with metal recycling, the carbon footprint of construction for a DAC application would be reduced to 6 g of CO_2 per kilogram of CO_2 captured. According to the future scenario in 2030, a large-scale DAC will require an additional 1.31 % of total electricity generation [24]. Global electricity generation will need to increase by 0.12 % to accommodate CO_2 storage in geological formations. The area required for 3,683 DAC plants on a large scale would be about 29 km^2 (~6% of the land area in the UAE is dedicated to agriculture, 490 km^2 [28]) and an additional 445 km^2 if wind energy was used as a source of electricity [24].

2.2. Carbon Engineering, Canada

Carbon Engineering (CE) is a Canadian company that has focused on developing and commercializing DAC technology since 2009 to remove CO_2 from the atmosphere based on an aqueous solvent–based DAC system [29] (Table 1, Entry 2). Using a continuous process of aqueous KOH sorbent coupled with calcium caustic recovery, CO_2 is being captured using CE's DAC technology. After many years of testing and research, CE launched its first pilot plant in British Columbia, Canada, with a capturing capacity of 350 metric tons CO_2/ year from the air in 2015. It was operating till 2020 and used for testing and research for further development toward commercial-scale processes [30]. CE's Innovation Centre was constructed in 2021, making it the world's biggest specialized DAC research and development facility. CE finalized the engineering design for the first large-scale commercial facility in 2022, utilizing data from the pilot plant and R&D facility [30]. Carbon Engineering is building currently the largest DAC facility, called the "STRATOS" facility, with a capturing capacity of half a million tons of CO_2 annually with the potential for scale-up to 1 million tons [31] (Table 1, Entry 3). It is expected that this plant will be operational by mid 2025 in Texas, USA.

The design ensures the continuous process operation by letting the air pass through the potassium hydroxide solution in the air contactor, then the CO_2-rich solvent is routed to further treatments to release CO_2 and regenerate the solvent (Fig. 2(c)) [32]. The process includes two connected chemical loops, and the first loop ensures the capturing of CO_2 from the atmosphere by reacting it with an aqueous solution with ionic concentrations of ~1.0 M OH^-, 0.5 M $(CO_3)^{2-}$, and 2.0 M K^+. In the second loop, $(CO_3)^2$ is precipitated by reaction with Ca^{2+} to form $CaCO_3$ while the Ca^{2+} is replenished by the dissolution of $Ca(OH)_2$. The $CaCO_3$ is calcined to liberate CO_2 producing CaO, which is slaked to produce $Ca(OH)_2$ [32]. Natural gas supplies the energy requirement for

regeneration. This technology can capture up to 73 % of CO_2 in atmospheric air [27].

Alkaline earth metal and alkali metal oxides and hydroxides (e.g., calcium oxide, sodium hydroxide, calcium hydroxide) have been investigated for DAC processes for their efficient and rapid CO_2 capture, but despite that, their development has been under questioning due to their high regeneration costs [33]. They are characterized by a superior affinity for CO_2 and could be regenerated by a reversible chemical carbonation reaction during the adsorption–desorption cycle of CO_2. Since KOH solution have strong alkalinity and offer fast reaction rates even with ultra-diluted CO_2, they have been investigated as sorbents for DAC processes [34]. KOH reacts with CO_2 to produce K_2CO_3, the last will react with CO_2 again to produce $KHCO_3$ which is soluble in water. Although the process performance is good, the energy requirements for regeneration remain significant. In order to regenerate the sorbent, CaO is added in water to form $Ca(OH)_2$, then the latter reacts with the salt resulted from the CO_2 and the alkali solvent reaction to form 2 products: $CaCO_3$ and the alkali solvent. Then, calcination of $CaCO_3$ is required to release pure CO_2 which needs a high operating temperature (≈900 °C), so a high energy consumption occurs, approximated to 180 kJ/mol CO_2 [35]. These methods have several disadvantages as well, such as solvent losses and salt impurities that lead to a loss of sorption capacity occurring during the calcium looping, as presented in Fig. 2c [32].

Natural gas is used to provide the heat demand that is more than 2,000 kWh/ton of CO_2 captured. It has been recorded that using natural gas, Carbon engineering DAC can emit 0.5 ton CO_2 / ton captured [15]. It might be possible to use carbon–neutral renewable synthetic natural gas (RE-SNG), but generating hydrogen from synthetic natural gas (SNG) would require approximately 4400 kWh [15]. As a result of high SNG production costs, there will be an increase in overall energy demand as well as production costs. It has been suggested in newer studies that a sustainable and affordable system should be completely electrified. For example, a fully electrified system requires 1,500 kWh of electricity for both power and heating per ton of CO_2 captured at 150 bar [15].

An LCA was performed on Carbon Engineering's technology and aimed at the capture and storage of 1 ton of CO_2, indicating that a total of 0.58 tons of CO_2 was emitted by the system [36]. This is considered relatively high due to the amount of heat required for CO_2 recovery from the sorbent. The use of a low-carbon energy supply (~70 g CO_2 emitted/kWh) can decrease the amount of CO_2 emitted to 0.26 tons /ton captured [36]. Regarding the utilization of a sorbent like KOH, it is important to extend its lifetime and limit environmental impact. In order to capture 1 gigaton per year the DAC units will occupy an area of at least 400 km^2, in addition to the area needed for DAC supply chains and the power supplied by photovoltaics, which is estimated to be 11,500 km^2 [36].

2.3. CSIRO, Australia

CSIRO stands for the Commonwealth Scientific and Industrial Research Organization. It is Australia's national science agency and one of the largest and most diverse scientific research organizations in the world. CSIRO was founded in 1916 and is an independent Australian government agency responsible for scientific research across various fields, including agriculture, health, energy, environment, and information technology [37]. CSIRO worked on different DAC projects, most of which are still in the early research stages. These projects are based on several capturing technologies including liquid absorbents (ACOHA and ENCORE projects), solid/liquid absorbents (Carbon Assist Project), and solid adsorbents (Airthena project, Fig. 2b).

In 2018, the CSIRO team initially examined the viability of utilizing amine liquid capture technology for DAC [38]. This investigation expanded on earlier laboratory studies and demonstrations of the technology's effectiveness in treating flue gas. The outcome of this research was the creation of the Ambient CO_2 Harvester (ACOHA) [39]. The captured CO_2 can be utilized as raw material in industries such as

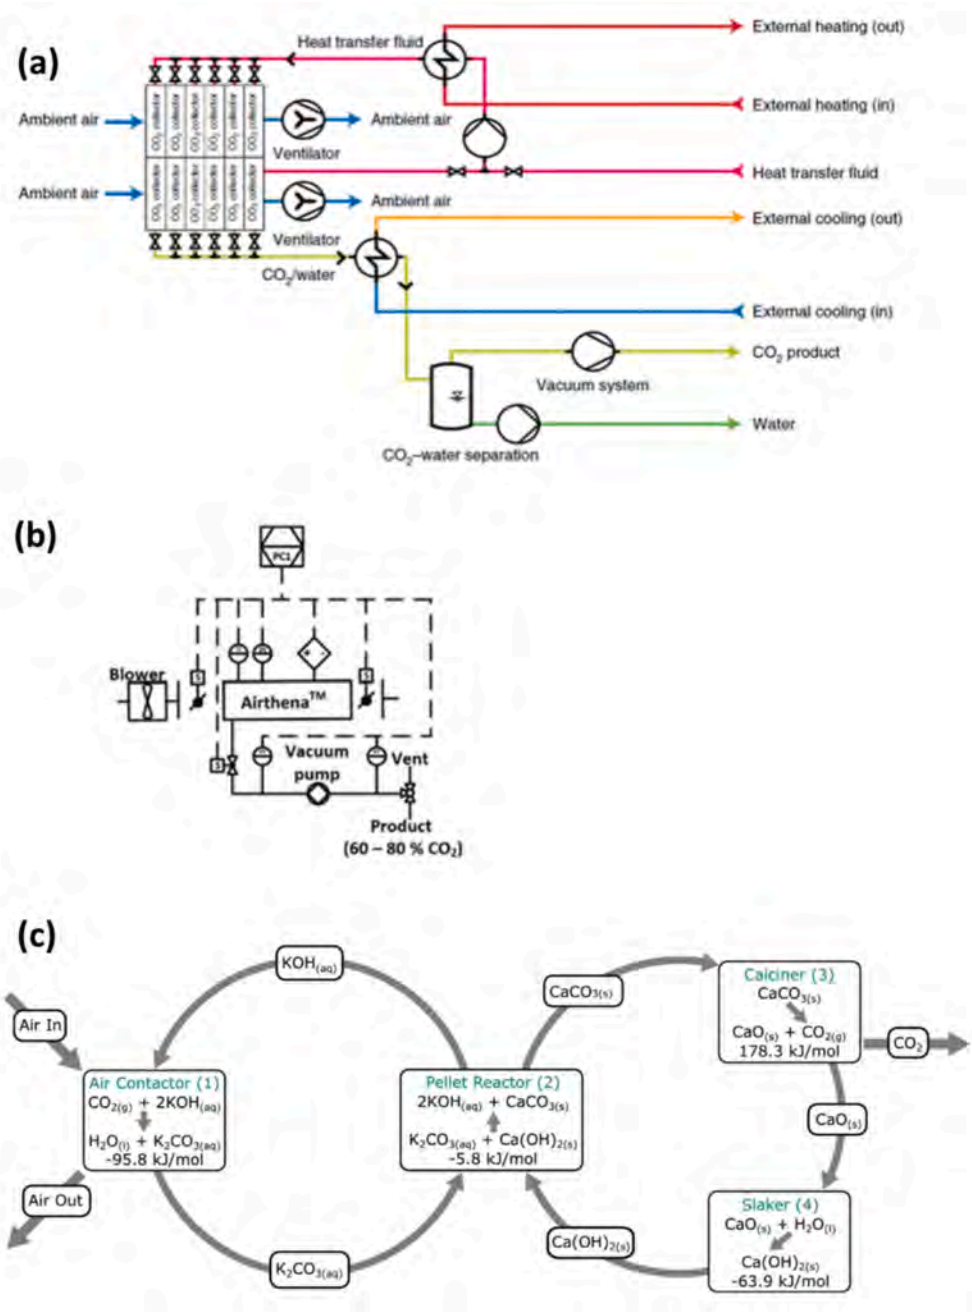

Fig. 2. (a) DAC process by Climeworks: Flow diagram of the DAC with 12 CO_2 collectors via temperature–vacuum swing adsorption [24], (b) Airthena-CSIRO Single DAC module [45]. (c) Carbon direct air capturing by KOH solution and calcium loop [32].

beverages, greenhouses, and fuel synthesis, or it can be stored. The ACOHA technology is adaptable for deployment at various scales [38]. The key strengths of ACOHA lie in its foundation on commercially available technologies, its potential to reduce costs through innovative processes and equipment, and its ability to quickly scale up for a significant impact on climate change mitigation [39]. The project's primary focus is on advancing DAC through liquid absorption technology, by incorporating innovative research in three critical areas: the formulation, investigation, and selection of liquid absorbents, the design and development of a cost-friendly absorber, and the process of solvent regeneration [40]. As also other efforts of CSIRO in DAC by absorption field, ENCORE project was also initiated with a partnership with Rolls Royce Plc [41]. The ENCORE project originated from the DAC solution developed by CSIRO, which is currently being utilized on a laboratory scale in Australia. The adsorbent is based on amino acid salts, for the purpose of capturing CO_2 from the surrounding air. The first phase of ENCORE is done including the study and design of the pilot plant demonstration by November 2021 [40]. The 2nd phase is to be implemented in the UK in 2024 [38]. Pilot plant constructed in phase 2 is planned to have a capturing capacity of 100 tons of CO_2 annually [40]. The carbon footprint of ENCORE system is expected to be ~0.12 ton CO_2 emitted per ton captured [40].

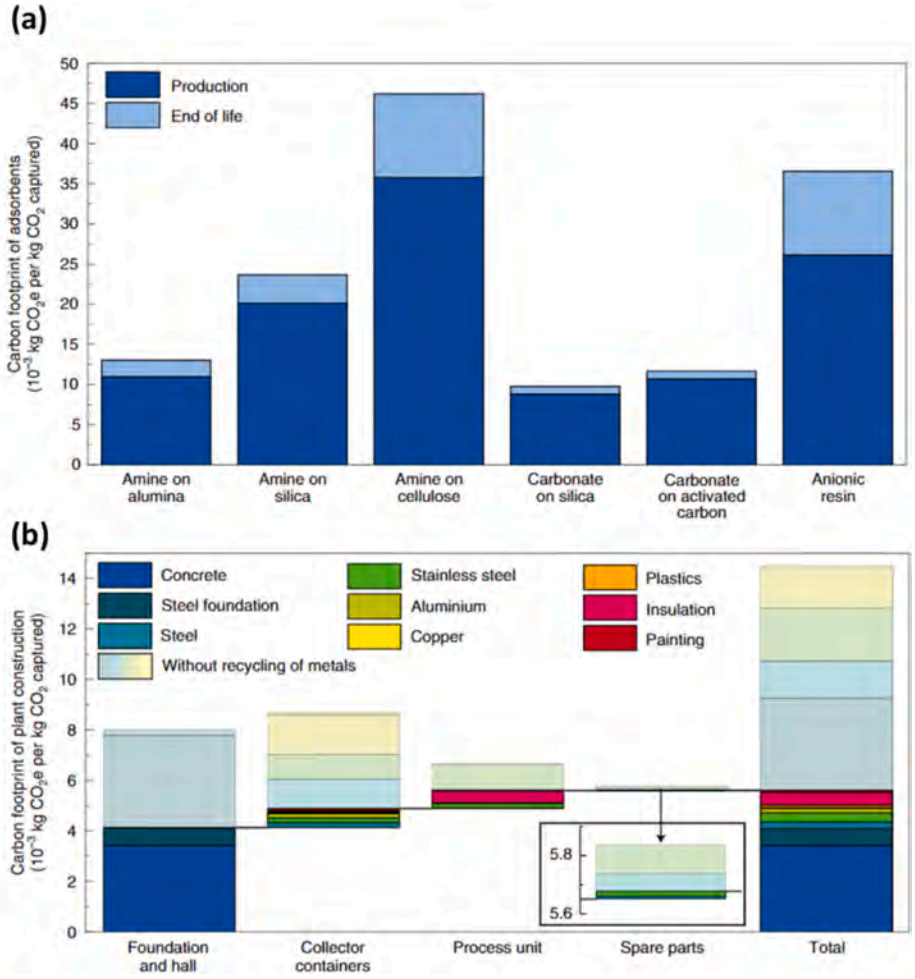

Fig. 3. (a) Carbon footprint of the 6 adsorbents suggested by Climeworks in their production phase and their end-life. (b) Carbon footprint analysis for Climeworks DAC plant construction with capacity of 4 kton/year CO_2 captured [24].

On the other hand, CarbonAssist employs an innovative sorbent material, comprising 30 wt% solid and 70 wt% liquid amine solvents, known for its remarkable selectivity in capturing CO_2 directly from air [42]. This material surpasses existing industry standards in terms of energy and heat consumption, cost-effectiveness, and efficiency. Encased within a two-part unit, the chemical system can be easily manufactured on a commercial scale. The sorbent operational lifespan ranges from 2 to 5 years, contingent on the specific application [42]. The research team is in the final stages of preparing a pilot plant in South Australia. The pilot plant is expected to have the capacity to extract 90 tons CO_2 /year, and efforts are underway to develop a larger second unit that can capture 365 tons CO_2 /year [38].

Airthena technology was announced in 2020 as an important breakthrough for CSIRO's procession in DAC (Fig. 2b) [43]. An adsorbent-based DAC system based on metal–organic framework (MOF) polymer nanocomposite was developed by CSIRO. The Airthena system is capable of producing 140 g of CO_2/ day with very low energy consumption (1.6 kWh/kg-CO_2 captured per module) during regeneration [44]. Two tons of CO_2 annually can be captured from the atmosphere using one module, which can be used for small-scale applications such as beverage carbonation and industrial cleaning [45]. Airthena is the only CSIRO's system with declared technical details and studied, thus it will be analyzed further in the coming paragraphs (Table 1, Entry 4).

There are 3 to 5 modules in the single Airthena's DAC demonstrator that process atmospheric air as a feedstock. With negligible back pressure, CO_2 is selectively stripped from the feed at a flow rate of 50 m^3/h per module. The blower, the adsorption chamber, and the vacuum pump make up a single module, as shown in Fig. 2b. The adsorption chamber includes the core of Airthena technology: a MOF/polymer nanocomposite and substrate configuration that adsorbs and desorbs CO_2. In a spiral configuration, thin layers of the MOF/polymer nanocomposite are coated onto long resistive heating sheets that are being incorporated in each adsorption chamber. A simple, energy-efficient, and low-cost technology called resistive heating is used in the regeneration phase [45].

For continuous operation of the Airthena's DAC process, Fig. 2b presents a simplified Process and Instrumentation Diagram. A parallel configuration is used for the three adsorption chambers. Hence, a smooth interchange of the adsorption and desorption phases is possible. TVSA is adopted as the adsorption-regeneration cycle [45] operating at 3 phases. The first phase is the absorption phase (1 h), where the fans allow air to flow into the chamber to capture CO_2. Subsequently, the regeneration phase (30 min) starts, and it is composed of 3 steps: In the evacuation step (15 min), the vacuum pump is activated to remove any remaining air within the module. In the desorption step (10 min), the vacuum pump is turned off, and the heaters are turned on. Within 10 min, the temperature is increased up to 80 °C to release CO_2 from the adsorbent. Then, in the collection step (5 min), the heaters are turned

off, and the vacuum pump is turned on to collect CO_2, which reaches 80 % purity. The adsorption-regeneration cycle is repeated after the collection step. When the collection step is over, a pause step occurs during which the operational module waits for other module to complete its cycle.

A pilot scale study on the Airthena demonstrator with 3 modules stated that each module has an average capacity of 3 g CO_2 per cycle, and the entire demonstrator can capture a total of 8 kg CO_2 over 2680 cycles [45]. It was also revealed that the composite adsorbent performed very well with no obvious loss in capacity or stability. The produced CO_2 has a purity of 70–80 % over the 2680 cycles. An optimum desorption temperature of 80 °C was observed. The demonstrator needed a supply of 1.6 kWh/ kg of CO_2 captured for adsorbent regeneration per module and a total energy requirement of 2.28 kWh/kg of CO_2 captured per module. Airthena modules are highly stable in ambient air, can be placed in remote locations, and have low energy consumption, which can be met entirely by renewable energy. Solar photovoltaics showed the lowest cost of electricity to run the process (102 US$/ton of CO_2 captured). The cost can be decreased more if a source of waste heat is available to 46 US$/ton of CO_2 captured [45]. For upgrading the purity, additional energy costs must be considered. MOF-based adsorbents offer high affinity to water molecules adsorption, requiring water stripping or dehumidifier units to increase the outlet purity.

2.4. Global Thermostat, USA

Global Thermostat is a company that specializes on CO_2 removal technologies, particularly DAC, and it was founded in 2010. Global Thermostat has operated a pilot and commercial demonstration plant at SRI International in Menlo Park, California, since 2010 [15] (Table 1, Entry 5).

The company provides DAC technology with a similar concept to Climeworks' DAC via adsorption but using amino-polymer-based adsorbent [15]. In the modular units, CO_2 regeneration occurs at 85–95 °C and happens in less than 100 s [6]. The outlet purity of CO_2 is $>$ 98.5 %. Sub-atmospheric pressure saturated steam is utilized to supply the required heat with 50 % heat recovery [15]. To decrease the final system costs, Global Thermostat designed a high-efficiency system and developed its amino-polymer-based adsorbent to reduce the full cycle time to less than 30 min. At the end of 2022, Global Thermostat started operating its first commercial-scale DAC plant with a capturing capacity $>$ 1,000 tons a year in Colorado [46]. The electricity demand is 150–260 kWh per ton CO_2 captured and heat demand is 1170–1410 kWh/ton CO_2 captured [15]. In this plant, Global Thermostat stated that the cost of CO_2 capturing will be targeted to achieve less than 150 US $/ton [15].

2.5. Other DAC systems

In addition to the described systems, other companies have been developing in this field with their technologies. As there is no publicly available information regarding the technical and financial aspects of these systems or their pilot-scale demonstration, this review will nominate some representative technologies among them with a brief description for each.

Skytree, founded in 2008 as a spin-out of the European Space Agency and based in the Netherlands [15], commercializes electrostatic absorption technology and moisturizing desorption technology (80–90 °C) for capturing CO_2. The key principle behind electrostatic absorption technology involves the use of electrically charged surfaces or fields to attract and capture particles, then, the desorption happens by moisturising of CO_2-rich sorbent. Ion-exchange resin serves as a pivotal component in this technology [15]. Thin resin sheets are initially exposed to the surrounding air, ensuring unimpeded airflow through the material. Once the loading process concludes, the sheets are transitioned into a sealed system. Within this closed environment, air is extracted, and moisture is introduced. Subsequently, the resin, upon contact with water, desorbs CO_2. Skytree's carbon capture system launched for indoor farming at Growy vertical farms in the Netherlands in 2022 is the company's first On-site Carbon Capture [47].

Infinitree is a carbon capture company located in New York that uses an ion exchange adsorbent to directly capture CO_2 from air [15]. It adopts the same working principle of Skytree, the moisture swing adsorption. It has an operating pilot plant in New York with a capturing capacity of 100 ton CO_2/year [6].

Soletair Power, headquartered in Lappeenranta, Finland, has been diligently working and developing the integration of DAC in buildings since its launch in 2016 [48]. Integrating this technology reduces buildings' emissions by up to 50 %, supports employee wellbeing, and provides a non-fossil resource that can be reused in a variety of ways [48]. Currently, they offer three types of DAC units, which are: (1) Outdoor CO_2 capture unit [capacity of up to 1,000 tons/year] (2) Building HVAC integrated CO_2 capture unit [capacity of up to 20 tons/year per] (3) Indoor CO_2 filtering and purifier unit [48]. A TVSA process and amine-functionalized adsorbent are utilized by Soletair Power within its carbon capture systems [48]. In 2018, they commissioned a demonstration facility [49]. DAC along with an electrolyzer for hydrogen production were utilized to provide the feedstock for a hydrocarbon production reactor. A total of 6.2 kg of wax and oil were produced each day during the 300 h that the pilot plant was operating [49].

Verdox, established in late 2019, is in the process of bringing its electroswing adsorption (ESA) platform technology to the commercial market. Originally conceived at MIT, this technology is designed for extracting carbon dioxide from both industrial emissions and the atmosphere. The company asserts that this approach leads to a 70 % reduction in energy consumption compared to conventional methods via absorption and adsorption [50]. Verdox has developed a prototype for DAC that utilizes electrochemical cells. In this ESA process, the cells are charged to capture CO_2 and subsequently discharged to produce a purified CO_2 stream for storage or utilization. The prototype incorporates quinone electrodes, which exhibit a strong attraction to CO_2 molecules when negatively charged but do not retain this affinity when the charge is deactivated [13]. In laboratory experiments, it has been demonstrated that the system can endure a minimum of 7,000 cycles of charging and discharging, experiencing a 30 % decrease in efficiency over that duration [51]. While a comprehensive techno-economic analysis has not been published yet, it has been estimated that the combined capital and operating costs for capturing one ton of CO_2 range from 50 to US$ 100 [51].

2.6. DAC commercial systems comparison and discussion on scale-up

Based on the regeneration temperature required, DAC technologies are categorized as either low-temperature solid sorbent systems, or high-temperature aqueous solution systems [10]. The processes based on DAC by adsorption are mainly categorized as low-temperature solid sorbent systems because the temperatures needed to regenerate these adsorbents are generally lower than the temperatures needed to regenerate liquid absorbents [10]. However, the reversibility of adsorption or absorption processes is influenced by factors such as the nature of the materials involved, the specific interactions at play, and the overall thermodynamics of the processes.

2.6.1. Low-temperature solid adsorbents

Technologies in this group involve an adsorption chamber containing the solid sorbent, where cyclic adsorption and desorption operation is performed. Physisorption technologies demand lower energy for sorbent regeneration than chemisorption-based ones since the CO_2 capture is done by only weak van der Waals forces. Nevertheless, adsorbents like zeolites and MOFs necessitate the removal of water before CO_2 separation/capture due to their low selectivity of CO_2 to water

vapour making them more suitable for dry conditions. Interestingly, this aligns with the advantage of cold climates for physisorption DAC technologies [52].

External and internal diffusion resistance play a crucial role in determining the effectiveness of adsorption. Because adsorption is an exothermic process, it is generally advisable to use an adsorbent with high thermal conductivity [13]. This quality facilitates heat transfer leading to minimizing the risk of thermal degradation. In scenarios where CO_2 concentration in streams is low, the heat transmission to the system through adsorption tends to be slow. Typically physical interactions are involved, such as van der Waals forces or weak chemical bonds. While these interactions may be weaker than the chemical bonds occuring in the absorption process, they can still be effective for capturing gases [1,2]. For instance, adsorbents, such as Metal-Organic Frameworks (MOF-177 and MOF-74), Zeolite 13X and 5A, activated carbon, and carbon nanotubes (CNTs), have microporous structure with high surface areas and tuneable pore sizes, therefore, are specifically designed to utilize on van der Waals forces to effectively adsorb CO2 at low concentrations [3]. While these interactions may be weaker than the chemical bonds occuring in the absorption process, they can still be effective for capturing gases [53,54]. In adsorption, CO_2 molecules adhere to the surface of a solid material. Thus, the capacity may be limited by the available surface area on the adsorbent. Subsequently, increasing the capacity of adsorption-based DAC plants may be also limited by land use. Adsorption also often has various constraints that affect its productivity, including low CO_2 selectivity and lower removal efficiency when compared to alternative technologies such as absorption processes. The removal efficiency of CO_2 by low-temperature DAC systems is controlled by the emissions resulting from operating the system which is mainly dominated by the source of energy, found to be ranging from approximately 8 % to approximately 95 % [55]. It's important to note that Climeworks produces the highest purity CO_2 of ~99.9 % because of adding subsequent units to condense the water content captured during the process.

Concerning low-temperature DAC systems, the primary contributor to the overall energy requirement is the heat consumed during the desorption phase [56]. The necessary regeneration temperatures typically range from 80 to 120 °C, significantly lower than those in the high-temperature DAC processes, at around 800 °C for KOH regeneration [13]. Consequently, low and medium thermal sources like geothermal, solar, and waste steam heat can be employed for adsorbent regeneration. Electricity is predominantly utilized for CO_2 compression, airflow through the porous structure, and for operating the vacuum pump to eliminate products and waste during the de-airing and desorption. Generally, the thermal energy required falls within the range of 4–7.5 GJ/ton CO_2 captured, while electricity consumption hovers around 200 to 700 kWh/ton CO_2 captured [56].

Implementing heat recovery systems to capture and reuse the heat generated during the adsorption process is of major importance as this can significantly reduce the overall energy consumption. Integrating renewable energy sources, such as solar or wind power, to supply energy for the adsorption process is also important as this can help reduce the reliance on non-renewable energy and lower the carbon footprint [11]. Investigating advanced regeneration techniques, such as microwave or radiofrequency heating, to achieve faster and more energy-efficient desorption also deserves attention.

2.6.2. *High-temperature liquid absorbents*

According to Carbon Engineering, KOH-based DAC can capture ¾ of CO_2 in the inlet air [43]. However, after considering the carbon emitted by the use of natural gas to provide the energy requirements of the system, the capturing capacity turrns to be less. With identical electricity supply conditions, low temperature DAC (LT-DAC) exhibited a greater carbon removal efficiency compared to high temperature DAC (HT-DAC), falling within the range of 45 % to 70 % [56]. Generally, DAC systems utilizing robust hydroxide sorbents demonstrate lower efficiencies in comparison to adsorbent-based DAC systems. This difference is attributed to the elevated temperature (800–900 °C) needed in the former to release CO_2.

During HT-DAC process operation, the solvent's regeneration process imposes the highest burden on the system's energy requirements. Using CE's technology as the typical process of this type, the calcination of $CaCO_3$ constitutes the most significant portion of the heat demand, specifically 5.25 GJ/ton of CO_2. Additionally, ~360 kWh/ton of CO_2 is needed for CO_2 compression, a cryogenic air separation unit for O_2 production, and to power the fans and pumps [56]. Among these, CO_2 compression is the most energy-consuming, accounting for almost 37 %, followed by 22 % for the air contactor and 22 % for oxygen production. Generally, for typical HT-DAC systems, the heat demand ranges from 5 to 9 GJ/ton of CO_2, and electricity demands range from 350 to 770 kWh/ton of CO_2 [56].

The high-temperature requirements of the HT-DAC systems limit the flexibility of renewable energy utilization. An ideal scenario for HT-DAC would be to run on low-carbon fuels, like biomethane or electrolytic hydrogen from renewable sources. There is potential for HT-DAC to transition to fully electric operation in the future, but at the moment this is only feasible on a small scale [4]. The commercial-scale HT-DAC system is designed to use natural gas as a source of heat and capture CO_2 produced by gas combustion, eliminating the need for additional capture equipment [4]. As a result, HT-DAC's emissions are significantly reduced while carbon is still removed. Nevertheless, in the future, if renewable energy sources can be used to provide high-temperature heat, carbon emissions could be further reduced, maximizing revenue opportunities [4]. Fast-tracking the commercial availability of large-scale electric calcination technology is considered a top necessity in order to facilitate HT-DAC plants running exclusively on renewable energy.

In the case of HT-DAC systems, a LCA studied three scenarios formulated by altering both the heat demand and the sources of electricity [57]. Findings revealed that in the baseline scenario, a carbon removal efficiency of 62 % could be achieved when the electricity demand was fulfilled by a natural gas combined cycle power plant. In the best and worst-case scenarios, where solar photovoltaic (PV) and the average coal-fired power plant in the USA were used as electricity sources, the carbon removal efficiencies were determined to be 93 % and 10 %, respectively [57].

2.6.3. *Cross-technology limitations, energy, and cost analysis*

In this section, low-temperature scaled-up DAC systems are compared first. While Global Thermostat shows a lower demand than Climeworks in terms of total energy requirements, the Airthena technology has not been tested yet for large scale or being scaled up as opposed to Global thermostat and Climeworks technologies which have been studied extensively at large pilot level. Airthena systems however require a lower temperature (80 °C) compared to the rest, likely to reduce at scale the process energy consumption, and Climeworks requires the highest temperature (100 °C). Based on the produced CO_2 purity, the Airthena system provides purity (70–80 %) less than the other two companies, so additional treatment will be required. The highest purity (99.9 %), which is provided by Climeworks, eliminates the necessity for further treatment and thus additional costs. Climeworks, also, achieves a very high capturing efficiency of 90 %, which none of the technologies can provide, according to recent literature. Based on the previous discussion and available information, it can be concluded the the Climeworks system is the most mature LT-DAC system for commercial scale. The cost imposed by this technology can be a challenge, but Climeworks predicts that by 2030 carbon removal costs will be below US$ 250/ton [58].

Climeworks is the only LT-DAC–based company with available disclosed information, so many LCAs and techno-economic assessments were done on their technology thus it will be further compared with CE's technology (HT-DAC). Based on total energy demand, CE's system requires a higher demand than Climeworks, and this is justified by the very

high regeneration temperature (800–900 °C) required to regenerate the KOH solution and the need for other further treatment units in the CE system e.g. slacker. The current cost of CE's technology is not disclosed, nevertheless, their expected cost to be reached by 2025 is 94–232 US $/ton CO_2 captured. Yet, the purity provided by CE (97.1 %) is still lower than Climeworks however it is still high and does not need further treatment. According to the land use, the 'ORCA' plant by Climeworks, with a capacity of 4,000 metric tons per year, has a size of 798.9 m^2 [6]. The 'STRATOS' plant by CE, with a capacity of 1 million tons/year, has an estimated area of 200,000 m^2 [6]. In general, the indirect land occupation related to the supply chain for HT-DAC systems is about four times greater than that of the LT-DAC systems, specifically the temperature swing-based ones. This difference is primarily attributed to the manufacturing and end-of-life stages of DAC units and adsorbents [36]. By levelising the annual plants' capacities per area, it is noticed that both plants are capable of capturing annually 5 tons of CO_2 /m^2. Carbon capture and regeneration units are separate in HT-DAC systems, which enable continuous carbon absorption and regeneration. In contrast, LT-DAC technology combines adsorption and desorption in one unit. This limits each step's operating time. There may be an increase in the cost of time management and storing of renewable energy heat, as a result of this [15]. A techno-economic assessment used CE as a base case for HT-DAC with an electrified system and Climeworks' technology as a base case for LT-DAC [15]. Electrified systems for DAC use electricity to power the capture process. The levilesed costs of HT and LT in 2020 are 878 US$/ton CO_2 captured and 788 US$/ton CO_2 captured, respectively [15]. The electricity demand of HT-DAC and LT-DAC are 1,535 and 250 kWh/ton CO_2 captured, respectively. LT requires an additional low-temperature heat demand of 1,750 kWh/ton CO_2 [15]. The costs of HT/LT are expected to decrease by 2050 as follows: 2030 (378/338 US $/ton CO_2), 2040 (265/237 US$/ton CO_2), and 2050 (222/199 US$/ton CO_2) [15].

From a carbon footprint viewpoint, for the capture and storage of 1 ton of CO_2 via HT-DAC and LT-DAC, 0.58 and 0.30 tons of CO_2 will be emitted into the atmosphere, respectively [36]. The primary factor influencing life-cycle greenhouse gas emissions in the process is the need for process heat to extract CO_2 from the sorbent [36]. The carbon footprint for DAC systems can be minimized by the use of low-carbon energy sources or better energy integration configurations, as discussed in the previous section for each case. Since HT-DAC systems require the highest energy for regeneration they impose the highest carbon footprint.

Water demand in the DAC system can also play a role in the sustainability of the related technologies. The amount of water evaporated, during the DAC process at high-temperature with aqueous solutions, may vary from 0 to 50 tons/ton CO_2 captured [15]. This evaporation is contingent to factors such as the temperature and humidity of the surrounding air, as well as the salt concentration of the solution. The regeneration process in HT-DAC involves several processes that impose elevated temperatures, which can lead to water evaporation and loss; Keeping a constant amount of water in the alkali solution is important to control the absorbtion kintics. For instance, Carbon Engineering's new design requires 4.7 tons of water/ton CO_2 captured at ambient conditions of 64 % RH and 20 °C [15]. Climeworks can however capture 0.8–2 ton of water/ton of CO_2 captured [15]. LT DAC systems may therefore become a net near-deionised water producer to sustain other processes, representing an added value to the process.

CO_2 low concentrations in the air is the most challenging obstacle to DAC economic feasibility. This is why very highly selective materials are required to be applied in DAC applications. Nevertheless, the contaminants in air and compositions can vary from day to day and from location to location. The low concentration of CO_2 in the air allows other gases present to compete with CO_2 on active sites of the capturing sorbent. The most important contaminant that could affect the capturing process is humidity. The water vapor content can decrease the capturing capacity of CO_2 for most DAC systems based on physisorption materials, such as MOFs and Zeolites, due to competitive adsorption. However, this can be easily solved by introducing a condenser before the capturing chamber to dehumidify the inlet air, as done in Climeworks technology.

After extracting CO_2 from the atmosphere, there are multiple options for its utilization. It can either be stored underground for long-term removal or employed directly for various purposes, such as beverage carbonation, fertilization in greenhouses, or as a refrigerant. Additionally, CO_2 can be used indirectly as a feedstock for processes that generate chemicals, fuels, and building materials. Among the 18 DAC plants currently operational globally, only two are storing CO_2 in a specifically designated storage site, which are Orca and Arctic fox ClimeWorks' plants [4]. The remaining 16 plants are capturing CO_2 for immediate use in nearby industrial facilities. CO_2 has several storage options, including geological storage in deep saline aquifers, depleted oil and gas fields, and other rock formations. The expenses and time required to establish CO_2 storage facilities vary based on the location and are influenced by factors such as the availability of subsurface data and reservoir properties. The costs associated with CO_2 storage can be relatively low. For instance, more than half of onshore storage in the United States is projected to be accessible at a cost below US$ 10/ton of CO_2, and approximately half of its offshore storage is projected to be available at costs below US$ 35/ton of CO_2 [4].

2.6.4. Emerging technologies for DAC

There are several emerging DAC solutions that have been either proposed theoretically or else demonstrated at low technology readiness levels (1–3). These strategies include (i) membrane separation, as well as (ii) a hybrid process involving absorption and electrodialysis and will be presented in this section.

Membranes are amongst the most efficient methods of capturing CO_2 from flue gas-type effluents since they are relatively inexpensive, simpler to install and operate, and leave a smaller ecological footprint than sorption processes. To maximize membrane permeance for CO_2 capture from air, however, the materials selected should be fine-tuned with extremely CO_2-philic compounds, while the thickness of the selective layer of the membrane should be reduced to a nanoscale level to support fast transfer and extreme selectivity. However, to date, CO_2 separation with membranes is not yet commercially available on a large scale and still needs additional improvements to be used at very low solute concentrations of CO_2 in air and to be economically feasible. CO_2 gas separation from other gases is mainly accomplished using glassy or rubbery polymeric membranes. The main objective is to overcome and solve the trade-off between existing polymer permeability and selectivity [59]. As the main application of membrane gas separation, most polymers have been examined for removing CO_2 from methane [60]. As a starting initiative for using membranes in DAC, some studies investigated such polymer membranes in CO_2/N_2 mixtures. The performance of glassy polymers in separating CO_2, depending on their physicochemical properties, was promising. Glassy polymers studied, such as Poly(1-trimethylsilyl-1-propyne) (PTMSP), Polymers of intrinsic microporosity (PIMs), Poly(ether-Sulfone) (PES) are highly reproducible and have acceptable mechanical properties. However, their performance was significantly reduced as a result of physical or chemical attacks [60]. On the other hand, rubbery polymers could be considered a better choice for CO_2 capturing in DAC, since rubbery polymers, such as Polydimethylsiloxane (PDMS) & PEBAX, are not susceptible to physical aging as glassy ones. Table 3 compares gas separation of CO_2 in CO_2/N_2 gas mixture through membranes made of glassy and rubbery polymers, and new porous carbon-zeolite mixed-matrix membrane. For DAC application, selectivity less than 40–50 cannot be acceptable neither efficient because of the low concentration of carbon dioxide in the atmosphere. PEBAX, as seen in Table 2, is suggested as a promising and scalable material for membrane design for DAC. A simulated multistage membrane process, using ASPEN PLUS, was used to evaluate the potential of using membranes for DAC, specifically an ultra-thin free-standing siloxane nanomembrane and the energy requirements [61].

Table 2
Comparison of CO_2 separation performance in dry simulated air by different membranes.

Polymer/ membrane material	Details	Conditions (T/ P)	CO_2 permeance/ permeability	Selectivity (CO_2/ N_2)	Ref.
PEBAX MH1657 (60 % PEO,40 % PA6)	Thermoplastic polyether-block-amides Used in thin film composition membrane (TCM)	25 °C 2 bar	128 ± 17 Barrer	64	[120]
PDMS (polydimethylsiloxane)	Rubbery polymer Used in (TCM)	25 °C 2 bar	3,395 ±55 Barrer	11	[120]
PTMSP	Glassy polymer	25 °C	29,000 Barrer	10.7	[60]
PIM-1	Glassy polymer	30 °C 0.2 bar	2,300 Barrer	25	[121]
SABO −34 (30 %wt loading)	Porous carbon-zeolite mixed-matrix membrane	35 °C 1 bar	2,615 Barrer	31	[122]

The outlet concentration of the retentate gas was desired to be equal to 300 ppm. To model the separation, 4 membrane stages were considered. It was concluded that it is possible to achieve the target CO_2 concentration with membrane separation that has a CO_2 selectivity as low as 30. However, other gases also permeate faster in systems with low selectivity, leading to a rapid increase in CO_2 concentrations in the retentate streams. Therefore, the lower selectivity membrane should have a smaller area than a high selectivity one. As a result, the membrane should not release retentate gas with more than 300 ppm of CO_2. With highly CO_2 selective membranes, CO_2 emissions and pumps energy consumption are relatively low. The higher the selectivity, the higher the CO_2 concentration in the product gas, the larger membrane area needed, and the lower the energy required.

A combination of absorption and electrodialysis process was first proposed ~two decades ago in Germany. The method devised involve the intake of air, wherein the CO_2 present in the air is absorbed using a NaOH solution [62]. The CO_2 is then released in a nearly pure form by acidifying the product Na_2CO_3 with H_2SO_4. Subsequent steps involve the restoration of NaOH and sulfuric acid through an electrochemically driven membrane process (electrodialysis). Notably, the process exclusively relies on electricity, without the need for thermal energy. In 2009, the process underwent a redesign for continuous operation, eliminating the utilization of H_2SO_4 [62]. The essential acidification of the Na_2CO_3 solution was carried out directly in an electrodialysis cell. Despite these advancements, there has been no commercial application of the process.

Achieving efficient separation with membranes for DAC requires addressing several factors due to the low concentration of CO_2 in the feed; however, elevated pressure is not necessary for this process. The lower the concentration, the higher the selectivity needed. To maximize membrane permeance for CO_2 capture from air, the materials should be fine-tuned with highly CO_2 −philic compounds. Additionally, the selective layer of the membrane should be reduced to nanoscale thickness to support fast transfer and extreme selectivity. Surface functionalization of membranes using materials such as Polyethyleneimine, graphene oxide (GO), and zeolites can enhance CO_2 selectivity (>40). Moreover, directing air onto the membranes using a compressor can help achieve the necessary separation efficiency. For instance, a study simulated a multistage membrane process using ASPEN PLUS to evaluate the potential of organic-polymer membranes for DAC, specifically ultra-thin freestanding siloxane nanomembranes (34 nm thick), and their energy requirements [4]. The inlet pressure was set to atmospheric pressure, and the permeate pressure was set at 5 kPa. By using four stages of membrane separation in series with a CO_2 selectivity of 50, it was possible to achieve up to a 66 % CO_2 concentration in the product gas under ambient pressure conditions. This validates that high pressure is not required to achieve efficient separation using membrane-DAC.

2.6.5. *DAC scale-up, potential, and challenges*

The greenhouse gas (GHG) emissions of DAC configurations are significantly influenced by the source of energy supplied for heat and electricity during the CO_2 capture process. Waste heat is particularly environmentally advantageous as a heat source. The GHG intensity of the electricity mix on the grid is a critical factor for DAC configurations connected to the grid, and its impact varies by country. Countries that combine the use of waste heat with mixes of low GHG-intensive electricity demonstrate the lowest GHG emissions. For instance, Norway and Iceland achieved GHG removal efficiencies of 97 % and 94 %, respectively, obtained by an LCA study using the Climeworks DAC system as a base case [55]. In contrast, countries heavily reliant on fossil fuels for electricity, like Greece, experience high GHG emissions, almost reaching net-positive GHG emissions at 0.91-ton CO_2/ ton CO_2 captured for grid-coupled DACs [55]. Autonomous system designs emerge as a promising alternative, showing GHG removal efficiencies ranging from 79 % to 91 % [55], particularly in locations with ample solar irradiation, eliminating the need for fossil fuel-based grid electricity and heat consumption. The findings suggest that by employing geothermal energy as a heat source along with a predominantly renewable electricity mix, the efficiency of carbon removal can reach 93 % [56]. Under optimal conditions utilizing waste heat and low-carbon electricity, the carbon removal efficiency can almost reach 97 %. However, this figure can drop significantly to as low as 8 % when the grid electricity is predominantly sourced from fossil power [56].

The cost of and potential of DAC for countries and companies to implement remain crucial interrogations. By 2050, DAC should be able to remove gigaton-scale CO_2 for US$ 100/ton or less [6]. It may be economically viable to perform DAC is the price for the capture of a ton approaches US$ 100. As of now, DAC removal costs are between US$ 200 to 600/ton, which is far from the goal. Nevertheless, DAC cost will for sure vary from region to region. Demonstrations of DAC technology have already taken place in Europe and North America. These regions are deemed suitable for hosting additional DAC facilities due to their accumulated experience and the potential for co-locating with existing industrial centres, as well as established infrastructure for transporting and storing CO_2. Other regions that exhibit cost competitiveness for deploying DAC include those with exceptionally high renewable energy potential, such as North Africa and the Middle East. Additionally, regions with low natural gas prices, such as the Middle East and Russia, and those with a strong interest in CO_2 utilization, such as Japan, are considered viable for DAC deployment. At a regional level, it is anticipated that lower CAPEX for DAC will be in North Africa, China, Russia, and the Middle East, than in Europe and US due to cost-effective materials and manufacturing [4]. Regions abundant in gas resources, such as the Russia and the Middle East, are expected to have lower gas prices compared to Europe and the United States. Simultaneously, CO_2 prices are projected to be higher in Europe, the United States, and Japan ($\leq$USD US$ 250/ton CO_2) than in the aforementioned regions [4]. These factors collectively contribute to a regional decline in the cost of carbon captured via DAC by 31–43 % from 2020 to 2030 and by 10–24 % from 2030 to 2050 [4].

For DAC to be used to combat climate change by capturing CO_2, the scaling up of the process should be extensively studied and further developed. Below are some considerations and approaches involved in scaling up DAC [6,22]. The first one is technological advancement. Scaling up DAC requires the development and deployment of more

efficient and cost-effective technologies. A reduction in operational costs can be achieved by advancing and optimizing CO_2 sorbents, optimizing air contactors, and regeneration units. The recent focus has been on modular units and passive air contactors [6]. As for DAC equipment, improvements in its manufacturing and/or creation can lower the costs. As for the sorbents, after many cycles of loading and unloading, they deteriorate. Over time, this process reduces the sorbent's quality, which ultimately compromises carbon capture's efficiency and capacity. Hence, it is imperative to develop higher-capacity sorbents utilizing readily available materials such as biochar and silica [15]. Additionally, there is a need to discover more energy-efficient metal oxide adsorbents [15]. Addressing energy demands is another critical aspect, as the technology is currently hindered by high energy requirements. Implementing moisture swing techniques can potentially reduce the energy required for regeneration, while electro-swing processes may eliminate the need for thermal energy altogether [6]. Furthermore, utilizing low-cost, renewable power sources, such as recycling waste heat, to operate DAC plants has the potential to further reduce operational costs. Another approach to cost reduction involves the mass production of DAC units, prioritizing an increase in the quantity of units rather than their individual size [6]. By applying the principles of learning by doing in the mass production of DAC, it is anticipated that costs will decrease significantly and swiftly. Another important aspects to consider is the absence of governmental backing and policy support that pose a challenge to the widespread adoption of DAC on a large scale [14]. Political endorsement is undeniably a crucial element in enabling DAC technology, particularly in driving down its cost to below US$ 100 per ton. Initial investments and the establishment of supportive policy frameworks are essential for the successful implementation of mass production and deployment of additional DAC facilities. The last area to consider is integration with carbon management. Scaling up DAC should be accompanied by robust carbon management strategies. This involves developing infrastructure for CO_2 storage or identifying viable utilization options such as carbon–neutral fuels or materials production.

Other routes to mitigate CO_2 in environmental ecosystems should also be equally investigated and one of such, relying on stripping CO_2 from the oceans, referred to as Direct Ocean Capture (DOC), will be presented in the next section.

3. Direct ocean capture commercial pilot systems

Oceans are essential to the global carbon cycle due to their vast carbon storage capacity, of approximating 38,000 gigatons [63], which is significantly greater than either the 700 gigatons capacity of the atmosphere or the 2,000 gigatons capacity of the terrestrial biosphere [64]. Additionally, oceans absorb ~2 gigatons of CO_2 annually, over two orders of magnitude greater than the amount in the atmosphere [65,66]. A new statistic depicted that ocean annual CO_2 sink during 2012–2021 was 26 % of total CO_2 emissions [67]. Ocean acidification is also a major concern for marine scientists since affecting marine wildlife. Marine calcifiers are particularly at risk as they make calcareous structures that are vulnerable to ocean acidification. Acidified seawater (at CO_2 levels from 1,000 μatm to 1,500 μatm measured for southern oceanwater) can dissolve $CaCO_3$ minerals and hinder calcification, causing increased fragility of calcareous structures [68,69].

Tactics to capture CO_2 from oceanwater rely on converting dissolved inorganic carbon from carbonates and bicarbonates into molecular CO_2, which may then be stripped at sub-atmospheric pressure [70]. The efficiency of DOC processes is influenced by the concentrations of dissolved CO_2, CO_3^{2-} and HCO_3^-, as well as the native ocean acidity. Since the solubility of CO_2 is greater at lower temperatures at high-latitudes, the oceanic CO_2 uptake therefore varies depending on the global ocean location, representing a significant factor when designing effective CO_2 capture strategy [71,72].

This section will discuss the potential of DOC technologies as well as current design attempts of pilot-scale DOC systems for CO_2 removal. Besides, critical analysis related to technical considerations, and a techno-economic discussion on the challenges faced towards scale-up will be presented.

3.1. Electrochemical pH swing DOC systems

The electrochemical pH swing process involves regulating the production of protons (H^+) and hydroxide (OH^-) by applying a gradient of potential between the anode and cathode. This transition from an alkaline to an acidic pH aid in the trapping and subsequent release of CO_2. By adjusting the potential difference, the local pH of the cathodic and anodic compartments can be modified in two ways i.e. a high pH environment is created at the cathode to capture CO_2 as HCO_3^- or CO_3^{-2}, while a low pH environment is established at the anode to release free CO_2 [31]. The electrochemical process can produce pure CO_2 that can be directly utilized for the production of high-value chemicals and fuels. The treated water, following CO_2 release, is subjected to a pH increase to counteract acidification and facilitate atmospheric CO_2 absorption prior to its release into the ocean. Such a process holds significant potential for various industrial and commercial applications. The resulting CO_2 purity and the pH adjustments to the treated water are important factors in ensuring the efficient utilization of the process [31,73]. Electrochemical capture encompasses several techniques, including but not limited to organic redox, pH-swing (utilizing methodologies such as bipolar membrane electrodialysis, electrolysis, capacitive deionization, H^+ (de) intercalation, and proton-coupled electron transfer (PCET) of organic molecules), and high-temperature molten carbonate cells. Hybrid methods involve combining electrochemical CO_2 capture and conversion approaches with battery systems [74].

At present, four primary forms of electrochemically mediated pH swing processes were employed for DOC, including Bipolar-Membrane Electrodialysis (BMPED), Electrochemical Cation-Exchange (ECE) process, Electrochemical Hydrogen Looping (EHL), and asymmetric Cl-mediated electrochemical process. In the following section, the efficacy of these techniques will be discussed in terms of energy requirements and CO_2 capture efficiency [75–79].

3.1.1. BMPED cell

BMPED provides more efficient energy means for capture and release of CO_2 from oceanwater dissolved inorganic carbon (DIC) using renewable electricity, making it a potentially valuable tool in the fight against climate change [75] (Table 3, Entry 1). In a BMPED cell, a voltage is applied across the cell whereby seawater is dissociated while BMPED membrane stack, made of ion-selective bipolar membranes only enable H^+ to and OH^- ions to counter-diffuse. The increase in concentration of H^+ ions led to a pH shift in the carbonate buffer and alter the dissolved inorganic carbon concentration within the oceanwater, resulting in the conversion of HCO_3^- and CO_3^{2-} into dissolved CO_2. The subsequent vacuum stripping of CO_2 produces pure CO_2 gas, while the acidified CO_2-free oceanwater undergoes alkalization to restore its initial state before being released back into the ocean [75]. Utilizing a thermodynamic model that considers the speciation of DIC in ocean water, an analysis was conducted to examine its precipitation. In this model, four types of equilibrium reactions were included, namely gas–liquid, acid-base, complexation, and precipitation reactions. The simulation revealed that DIC is extracted from the oceanwater when pH values becomes less than 4, specifically, at a pH of ~5 % of DIC is converted to dissolved CO_2 [31].

The feasibility of the in situ BPMED to mineralize oceanic DIC into carbonate minerals via alkalization route was introduced [80] (Table 3, Entry 2). Purpose of in situ alkalization was to minimize the electrical energy consumption of the process. To begin, Visual MINTEQ 3.1 was utilized to simulate the alkaline pH range that would optimize carbon capture and determine the minimum electrical energy needed for the pH-swing process. Then, a six-compartment cell equipped with a single BPM was fabricated to demonstrate the impact of pH on both carbonate

Table 3
Details of DOC type, CO2 capture capacity and capture cost of DOC lab-scale prototypes available.

Entry	Facility	Company/ Location	DOC Technology	Operational Parameters						CO_2 Capture efficiency (%)	Cost US $/ton CO_2 captured	Ref.
				Temperature (°C)	pH	Current Density mA/cm^2	Energy Consumption kWh/ton CO_2	Time (h)	Water Flow rate (mL/ min)

mineralization and membrane fouling. CO_2 capture experiments were conducted using both synthetic oceanwater and real seawater from the Wadden Sea in the Netherlands. Finally, the proposed concept was validated by using an upscaled BPMED cell that contained 10 bipolar-cation exchange membrane (BPM-CEM) cell pairs. These findings provide valuable insights for the industrialization of seawater carbon capture through mineralization. At constant current density of 5 mA/cm^2, oceanwater flow rate of 68 mL/min, 60 % of DIC from real oceanwater and 58 % from synthetic oceanwater was extracted in 0.5 h without adding any additional chemicals as shown in Table 2, Entry 1. At optimized current density and flow rate, total energy consumption for the in situ pH-swing of ca. pH 3.2–9.75 was 325 kJ/mol $CaCO_3$ for DIC capture from real oceanwater. Theoretically, at a mild-pH swing, the thermodynamic energy required to capture $CaCO_3$ though in situ mineralization is ~35 kJ/mol $CaCO_3$ which is less than 10 % of that experimentally achieved. However, the irreversible BPM-overpotential account for more than 55 % of the required electrical energy [80].

A nine-cell pH-swing BMPED system was built to extract CO_2 from

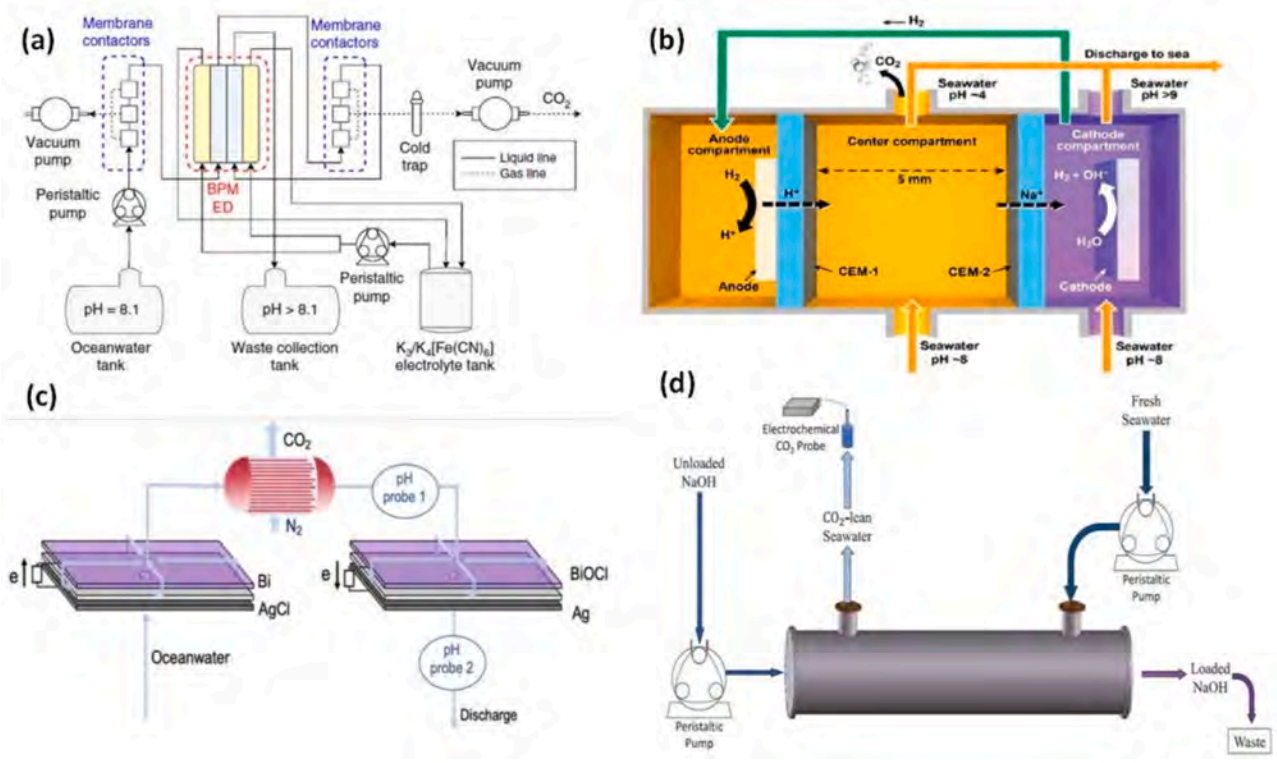

Fig. 4. The experimental flow diagram of the lab-scale electrochemical DOC systems: (a) BMPED cell [76], (b) EHL flow cell [99], (c) asymmetric Cl-mediated cell [77], and (d) HFMC cell [86].

oceanwater. Each cell consisted of a basified solution compartment, a bipolar membrane (BMP), an acidified solution compartment, and an anion exchange membrane [81] (Table 3, Entry 3). A cation exchange membrane was used at both ends of the membrane stack to separate it from the electrode compartment (titanium with an iridium-ruthenium based coating). The rate of CO_2 gas extraction was increased as the pH of the acid solution dropped until a steady-state equilibrium was reached. To compare energy efficiency of system, CO_2 extraction was measured at different oceanwater flow rates at a normalized current of less than 1 mA/cm^2. A prototype cell displayed 59 % extraction of CO_2 in 30 min at an electrical energy expenditure of 242 kJ/mol CO_2, at oceanwater flow rate 3.1 L/min, at pH 5 as given in the Table 2, Entry 2. CO_2 removal efficiency was further increased to 68 % by increasing the flow rate to 6 L/min and lowering pH to 3.7 value, with a small increase in the energy to 285 kJ/ mol (CO_2) [81]. The energy consumption estimates given here may not however account for the energy required to pump the oceanwater solution through the system or to vacuum strip CO_2 from acidified oceanwater which could require for extra 10–15 % gross energy.

In order to improve the energy efficiency for CO_2 extraction and conversion, one additional set of membranes was incorporated into BMPED system (as depicted in Fig. 4(a)) for removal of input gases from oceanwater such as O_2 and N_2 [76]. This BPMED cell was comprised two oceanwater compartments partitioned by a bipolar membrane (BPM), two reversible redox-couple compartments, each delimited from the oceanwater compartment by a cation exchange membrane (CEM) and two electrodes for electrochemical reactions. By using two sets of membrane contractors, the BMPED system displayed 88 kJ/mol less energy consumption as compared to BMPED system using single set of membrane contractor. The BPMED device demonstrated high efficacy in removing CO_2 from oceanwater with a capture capacity of 71 % for an electrical energy consumption of 155 kJ/mol CO_2, oceanwater flow rate of 37 mL/min, a pH value of 4.7 for the acidified stream, and a total voltage of approximately 1 V in 1 h, as displayed in Table 2, Entry 3. Furthermore, the designed BMPED unit was coupled with another CO_2 reduction cell (CO_2R) to convert CO_2 into other fuels and chemicals. CO_2R cell converted CO_2 into ethanol, propanol, and carbon monoxide (CO) at Faradaic efficiency (FE) of 73 % and 95 % at 58 mA/cm^2 using Cu and Ag electrocatalysts respectively. By contrast, energy required for conversion of CO_2 into fuels is higher, for example to conversion of CO_2 into methane requires 13.9 kWh/kg of CO_2, whereas, CO_2 extraction from oceanwater requires 0.98 kWh/kg of CO_2 which would be small fraction of capture and conversion energy combined [76].

Captura, a spinoff of the California Institute of Technology, has launched the first DOC pilot plant off the coast of Newport Beach, CA in 2021 [82]. The plant can capture 100 tons of CO_2/year using a system based on the electrodialysis process that uses renewable energy to split water molecules into an acid and a base. The captured CO_2 is stored for further utilization, while the decarbonized water is returned to the ocean, where it interacts with the atmosphere to draw down an equivalent quantity of CO_2. The Captura's process is poised to make a significant impact on the fight against climate change by utilizing the ocean's natural ability to capture CO_2 from the atmosphere.

3.1.2. Electrochemical cation exchange cell

The Electrochemical Cation Exchange (ECE) cell, developed by the Naval Research Laboratory, is a sophisticated technology capable of extracting CO_2 and H_2 from oceanwater in a single process [78] (Table 3, Entry 4). The ECE cell was composed of four configuration modules, among which configuration of first three modules was based on commercially available electro-deionization cells. Fourth module was customized to reduce energy efficiency required for lowering oceanwater pH below 6. ECE includes a center compartment, electrode compartments for reversing polarities, and two cation-permeable membranes which separate the three compartments. A lab-scale prototype of the ECE system was created, which was then integrated into a portable skid. Alongside the ECE system, the skid also housed a reverse osmosis (RO) unit, power supply, pumps, membrane contactor CO_2 gas recovery system, hydrogen gas vacuum tower, and gas analyzer. The outcome was the creation of a comprehensive CO_2 and H_2 capturing system. pH of the seawater was changed by an applied current through E-CEM electrodes and the change was monitored by a standard combination electrode. Other components of the system (RO, E-CEM, well pump, vacuum towers, vacuum pumps, solenoid valves, and power supply) were controlled as an integrated unit. In order to remove CO_2 gas from seawater, commercial poly(ethylene) hollow fiber membranes contactors were used. A standard hydrogen gas vacuum tower simultaneously processed the water from the acting cathode compartment of the module as it released H_2 gas, which was qualitatively measured using a standard Honeywell gas analyzer as was the CO_2. CO_2 capture costs, and operational parameters for ECE cell are given in the Table 2, Entry 4. The pH of the oceanwater was adjusted based on the applied current to the ECE system, and it was reduced from 8.1 to less than 6 within just 20 min. The added configuration improved the pH lowering performance of the ECE system by 65 % that was a positive point in CO_2 capturing efficiency in shorter time duration. Natural Key West oceanwater with CO_2 concentration of 100 mg/L was used to calculate CO_2 capture efficiency. According to reports, when the pH level of ocean water drops to 6 or lower, the carbonate and bicarbonate present in it react to form CO_2 gas [83]. This process implies that at an operating current density of 7.0 mA/m^2, an ocean water flow rate of 460 mL/min, and a pH level of 5.5, the theoretical value for CO_2 capture is 0.0023 mol CO_2/L. It is expected that experimental H_2 and CO_2 capture will be performed in future with similar energy efficiency as that of commercial electrolysis given the faster polarity reversal of ECE system [78].

3.1.3. EHL cell

EHL systems are superior to BPMED and ECE DOC ones with respect to the fact that they require lower voltage and leading to greater efficiency for capturing CO_2 from ocean water (Table 3, Entry 5). For instance, at 10 mA/cm^2 current density, BPMED operates at 1.9 V and ECE operates at 1.73 V, whereas EHL operates at 0.48 V [79]. In EHL system, oxidation of hydrogen takes place at anode and the oxidized H^+ are transported though the proton exchange membrane to the center compartment where protons react with CO_3^{2-} and HCO^{3-} to produce acidified seawater and release CO_2 gas for storage. Seawater is then neutralized in the central compartment where hydrogen evolution results in the formation of NaOH at the cathode, thus basifying the solution. The flow diagram of lab-scale EHL system is shown in the Fig. 4(b) and operational parameters and capture costs are given in Table 2, Entry 5. Lab-scale designed EHL unit demonstrated 91 % CO_2 removal from oceanwater at a current density of 8 mA/cm^2, oceanwater flowrate of 40 mL/min, at pH 5.5, with record low electrical energy of 104 kJ/mol CO_2. The EHL flow cell demonstrates a major 56 % reduction in electric energy usage compared to the BMPED system, with a total consumption of 660 kWh/ton of CO_2. Additionally, the mild operating conditions and low operating voltages make the EHL system a potentially ideal candidate for scaling up protocols in DOC pilot plants [79].

Although EHL has a high CO_2 removal efficiency and requires less energy for commercial DOC purposes, there are still certain challenges to overcome, for instance, extra steps are required for the pretreatment of ocean water before pumping into system to prevent or reduce biofouling. These extra steps increase the complexity of the process and ultimately increase the overall cost of the system. For this purpose, integration of electrochemical oceanwater splitting device (EOSD) into global coastal economy would be helpful [84]. The integrated device would split oceanwater using O_2 and CO_2 from air by combining electrochemical and chemical reactions. Water electrolysis generates an alkaline electrolyte and concurrently capture CO_2 may hence reduce the amount of Ca^{2+} and Mg^{2+} ions present in solution due to their precipitation as carbonates. The EHL process was reported to yield 4.17 g of corallite, for a capture of 0.48 g of CO_2, and a production of 111.11 g of

H_2 using 7.446 kWh of electricity with only 0.051 kWh of electricity per liter of oceanwater input [84].

3.1.4. Chlorine-Mediated electrodialysis cell

Despite its high efficiency, the cost of membranes used in BPMED may hinder the commercialization of the process [85] (Table 3, Entry 6). In order to overcome this challenge, a solely electrochemical pH modulation process obtained with an asymmetric chlorine-mediated electrochemical system was implemented to reduce costs associated with using BPMs in electrochemical systems [77]. Besides being a membrane-free system with lower capital costs and lower energy requirements, the system was more simple to deploy than BPMED and offered very much reduced risks of leaking any redox complexes into ocean [77]. Bismuth and silver electrodes were employed to capture and release chloride ions by faradaic reactions and a chlorine-mediated pH swing was achieved through different reaction stoichiometry between the two electrodes, to effectively remove CO_2 from oceanwater. A schematic illustration of the system is shown in the Fig. 4(c), whereby within the Bi/AgCl feed cell, one electrode releases H^+ for acidification of oceanwater, while the counter electrode releases Cl^- to ensure charge balance. In the BiOCl/Ag cell, molecular CO_2 is captured using a hollow fiber membrane contractor, before being returned to the ocean following the reverse reaction and oceanwater alkalization. The new pH swing system displayed 87 % removal efficiency of CO_2 from oceanwater at, oceanwater flow rate 1.04 mL/min, pH value 6, operation time of 10 h, with energy consumption of 122 kJ/mol as depicted in Table 2, Entry 6 [77].

3.1.5. Hollow fiber membrane contactors (HFMCs)

A solution to lower the expenses incurred from electrochemical DOC procedures is implementing passive membrane-based contactors. HFMCs utilizing passive membrane technology have already been optimized for carbon capture systems following combustion. Consequently, they hold great potential as a viable option for DOC as well. In a recent work, a novel method utilizing HFMC for DOC was introduced in a multifaceted approach [86]. Fig. 4(d) depicts the lab-scale experimental setup for HFMC. NaOH was selected as the solvent due to its quick CO_2 absorption and proven track record in DAC systems. HFMCs employ gas-permeable membranes that are impermeable to liquids, necessitating the use of NaOH to drive dissolved CO_2 through the membrane from ocean water to the solvent side in a counterflow direction. A combination of experimental works and computational modeling as well as and techno-economic assessment were developed to analyze the efficiency of CO_2 capture from ocean water in both pilot and commercial systems. Instant sea Synthetic Sea Salt was used for experiments, and CO_2 concentration was reached 0.39 mol/L in solvent at ambient temperature, solvent flowrate of 200 mL/min, oceanwater flowrate of 200–1,200 mL/min, 16–20 h. HFMCs are a suitable option for large-scale gas exchange processes with slow kinetics as they provide a large contact surface area per unit volume for efficient gas exchange between two fluids. However, the investigation of common challenges associated with HFMCs for DOC purpose remains critical to reduce further costs as well as pressure drop and membrane fouling occurring during the process, prior to scaling up.

3.2. Carbonate mineralization DOC systems

Oceanwater is an excellent source of Ca^{2+} and Mg^{2+} ions that can react with CO_2 to form carbonate precipitates, which greatly aids in achieving CO_2 fixation [87]. To enhance the CO_2 capture capacity of oceanwater, it is recommended to utilize waste materials that are rich in Ca and Mg [67]. One such material is steel slag, which is cost-effective and contains up to 58 % of CaO and 10 % of MgO [88] (Table 3, Entry 7). With 0.4 % CaO, the solubility of CO_2 in oceanwater can reach up to 80 % at 25 °C and 0.3 MPa. A recent research paper has reported that, under ambient temperature and 0.3 MPa pressure, the concentration of carbonate precipitation in oceanwater increases by 115 % when the steel slag concentration is increased by 1 % [89]. The capture of CO_2 from ocean water utilizing steel slag involves three distinct stages, namely, aqueous CO_2 dissolution, Ca leaching, and $CaCO_3$ precipitation via the reaction between steel slag ions and dissolved CO_2. As solubility of CO_2 increases, the precipitation of $CaCO_3$ also increases resulting in an overall increase in CO_2 solubility in oceanwater. For CO_2 absorption, online chromatographic absorber was functioned at 1 atm pressure, 30 °C temperature and gas flow rate of 2,805 ton/h. Details of operational parameters and capture costs are displayed in Table 2, Entry 7. The steel slag to gas ratio was varied and when the optimal liquid–gas ratio was 250–280, 90 % CO_2 absorption was observed. Experimental procedure validity was also verified with simulations by Aspen Plus that further supported CO_2 capture and storage from oceanwater using steel slag with approximate absorption of 128 kg CO_2/ton of steel slag. Another study has reported use of cement kiln dust (CKD) (composed of 46.4 % Ca and 1.3 % Mg respectively) industrial by-product for CO_2 storage in the form of carbonates [90]. In this study, oceanwater was used as solvent to leach out Ca, precipitation of $CaCO_3$ and CO_2 storage from CKD. Concentration of eluted Ca was comparable with other methods of leaching, except some methods using HCl, NH_4Cl, and trisodium citrate solvents. Using oceanwater as solvent, in the absence of other chemicals, at pH value 12.5, solid/liquid ratio of 1/50, 3.35 kg Ca/L of CKD, 185 kg CO_2/ton of CKD and 615 kg $CaCO_3$/ton of CKD were obtained that was very significant value from CO_2 capture point of view. Amount of CO_2 captured in this study was higher than steel slag waste using 2 M HCl as solvent (128 kg CO_2/ton of steel slag). The results explain the potential deployment of this study for DOC purpose in future. Steel slag contains hazardous elements such as chromium (Cr) and arsenic (As), which may dissolve in water. The alkaline nature of steel slag can contribute to an increase in pH levels when dissolved in water, which is a critical factor to consider before disposing of it in the ocean. Before using CDK for CO_2 capture, it is therefore important to consider the sulphates, silicates and hydroxide content associated to hardness of the water.

3.3. DOC commercial plants prospects and plans

DOC operating principle lies towards shifting CO_2 bicarbonate–carbonate equilibrium into gaseous CO_2 or solid carbonate to achieve CO_2 capture [91]. The electrochemical and carbonate mineralization DOC systems have demonstrated high potential at the laboratory scale, yet the challenge of upscaling these systems remain a crucial hurdle. At present, the feasibility of electrochemical DOC systems operating at a commercially relevant scale remains unproven. Critical challenges include achieving a balance of the gas–liquid interfaces, which must be scaled up from a few cm^2 to hundreds of m^2, to be relevant for DOC operations [92]. Notwithstanding, the rapid evolution of scaling technology in this area is expected to result in large-scale production of these systems within the next decade. In view of this, a discussion on prospects for commercial DOC systems is done below in terms of performance, energy requirements and capture costs.

Captura, California (Pasadena), USA, using Caltech Laboratories, proposed a HFMC electrolysis DOC system to capture CO_2 from oceanwater. Low-cost hollow fibers (~US$ 20–50/m^2) similar to the ones used for water filtration will be incorporated with polydimethylsiloxane modifications on outer layers for selective striping of CO_2 from oceanwater [93]. The DOC process will only use renewable energy without addition of other chemical and without byproducts production. Based on the ED concept used for pilot plant system, Captura's another DOC pilot plant has been successfully scaled-up in the Pasadena lab and moved it to AltaSea at the Port of Los Angeles in 2023 to start ocean water trials [82]. The company used a continuous flow of oceanwater to measure system performance and make necessary improvements. The scale-up DOC system captures 100 tons CO_2/year.

Equinor, Stavanger, Norway, a multinational energy company, has partnered with Captura to develop industrial-scale solutions to remove

CO_2 from the ocean [94]. The partnership will start with a pilot plant in Norway that can capture up to 1,000 metric tons of CO_2 annually. The pilot plant will be based at Equinor's Karsto natural gas processing facility on the west coast of Norway. It will follow a 1 ton/year system that commenced operations at Newport Beach, California in August 2022, and a 100 ton/year system that was recently installed at the Port of Los Angeles. The captured CO_2 will then be used for commissioning the Northern Lights facilities, which is the world's first open-source CO_2 transport and storage infrastructure. The pilot project will draw seawater and remove a measurable stream of CO_2 from it. The feasibility and design of the pilot project is already underway, with installation planned for the fall of 2024. The success of the pilot project can potentially lead to the development of large-scale commercial plants in key regions around the world [94].

Caltech is developing an offshore system based on electrodialysis concept to extract CO_2 from oceanwater [95]. To reduce system associated cost and processed water volume, project will be aimed to validate high current density, low power electrodialyzer stack and membrane contactors to facilitate CO_2 capture. The proposed system will provide a viable pathway to capture CO_2 at the cost of $<$ 100 USD/ton CO_2 and could be scaled up to multi-gigaton CO_2/year.

MIT has proposed battery-like electro-swing DOC system [96]. With its battery-like composition of electrochemical cells, this cutting-edge technology effectively releases CO_2 Ocean water, enhances the water's alkalinity, and returns the treated water back to the ocean. Its innovative design is set to revolutionize the way we tackle ocean acidification, and this system could be a significant step towards a more sustainable future. The proposed system boasts several noteworthy advantages. First and foremost, it obviates the need for expensive membranes or supplementary chemicals. Secondly, its ease of deployment renders it practical. Thirdly, it is free from byproducts. Additionally, the proposed innovative electrode configurations are highly effective at reducing transport and electrical resistance levels in the context of large water volumes. This system is characterized by low energetics, facilitated by renewable solar or wind resources, and can be installed on platforms or cargo ships.

The Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, have proposed electrodialysis concept to capture 2.4 ton of CO_2/h. This project involves the development of "Ocean Floating Islands" that would operate via electrodialysis, a process powered by solar energy for the simultaneous production of H_2 and extraction of CO_2 from oceanwater [70]. The proposed installation can be mounted on a fixed-hull ship, and would consist of 70 clusters, each with photovoltaic (PV) islands of 100 nm diameter. The total surface area covered by the PV islands would be 550,000 m^2, with the entire installation occupying a surface area of approximately 1 km^2. The PV islands will provide electrical power to the desalination and electrolysis cells for H_2 production, the electrochemical cells for CO_2 extraction, the catalytic reactors for methanol production and separation, storage batteries, a methanol storage tank, and other installed accessories. With a total incoming solar power of 120 MW and 20 % efficient PV modules, the system could produce an average of 24 MW_{el} of electrical power. At oceanwater flow of 41,000 ton/h, ED cells which consume 5.1 MW_{el}, could extract the dissolved CO_2 with 59 % efficiency, yielding 2.4 ton/h CO_2. Economically, a much larger electrodialysis flow (41,000 ton/h) would require a novel, highly cost-efficient method. It should be noted that a similar oceanwater flow rate is pretreated in the RO desalination plant using sand filtration with periodic backwashing [70]. Furthermore, the capital costs for oceanwater pretreatment equipment and floating island structures are highly uncertain.

The energy and environmental research center (EERC), nonprofit division of the University of North Dakota, located in Grand Forks, North Dakota, United States) has proposed DOC technology based on cyclic precipitation of carbonates from oceanwater in a process called hydrolytic softening [97]. This innovative process bears similarities to conventional water treatment methods. Essentially, the water is softened through the precipitation of dissolved inorganic carbon (DIC) as calcium carbonate via the use of hydrated lime. Hydrolytic softening presents a promising solution for the decomposition of calcium carbonate, allowing for the release of CO_2 gas that can be utilized for sequestration or industrial purposes. Furthermore, this process regenerates the lime for repeated usage, making it a sustainable and cost-effective approach for DOC. In comparison to other methods that rely on membrane electrodialysis, the proposed process can significantly reduce energy input costs by up to 77 %.

The Institute for Carbon Management at University of California, Los Angeles has proposed an innovative and scalable process design for DOC [98]. This new process involves a single-step electrolytic precipitation of carbonates. In this perspective, oceanwater (as an electrolyte) is pumped through electrolytic flow reactors, and dissolved CO_2 in oceanwater and atmosphere is combined with Ca^{2+} and Mg^{2+} species in an aqueous reaction medium. This innovative mineralization technology is notable for several significant advantages over other biotic or abiotic methods. Most notably, it efficiently eliminates the thermodynamic and kinetic challenges associated with carbonate precipitation by directly and in situ electrochemically converting dissolved inorganic carbon (DIC) into carbonate minerals. Furthermore, this process is significantly more time-efficient than natural rock-based mineralization techniques, which can require years to complete. Additionally, this method can be successfully applied across a broad range of CO_2 concentrations and temperatures, from ambient levels to 100 vol% CO_2 and from ambient to around 90 °C, without incurring any additional costs. Lastly, as a result of the electrochemical dissociation of ocean water, solvents are not required to stimulate CO_2 adsorption for ocean carbon management.

The deployment of DOC storage facilities may occur onshore, offshore, or mobile platforms. Onshore DOC operations are positioned along coastlines to capitalize on their adjacency to both the ocean and land. Offshore facilities are situated in the open ocean, with the captured CO_2 being conveyed to storage facilities located beneath the seabed, such as saline aquifers or depleted oil and gas reservoirs. In Norway, there are currently two prominent CO_2 storage facilities operational, namely Sleipner and Snøhvit, both situated in the Norwegian Sector of the North Sea. The Sleipner field, managed by the Norwegian energy company Equinor, has been engaged in the separation and re-injection of CO_2 as part of a carbon capture and storage (CCS) initiative since 1996. This initiative involves capturing nearly one million metric tons of CO_2 annually from the natural gas extracted at the field, and subsequently re-injecting it into the Utsira Formation–a deep saline aquifer located beneath the North Sea [6,7]. Captura seeks to establish partnerships with experienced carbon sequestration firms such as the Northern Lights project to facilitate the geological storage of captured CO_2. This process entails underground storage of CO2 in a supercritical liquid state, within depleted oil and gas formations or geologic saline aquifers. Stringently selected sequestration sites will ensure containment of CO_2, with the responsibility for monitoring and verification resting with the sequestration company [8]. Equinor and Captura will work together on different versions of Captura's technology for carbon capture and storage. They will start by building a 1,000 tons/y onshore pilot plant at Equinor's Kårstø natural gas processing facility in Norway. The plant will remove CO_2 from seawater and support the Northern Lights project, which aims to be the world's first open-source CO_2 transport and storage infrastructure [9].

3.4. Techno-economic assessment of DOC processes

For determining the feasibility of any DOC process for scaling up to large capture facility, techno-economic assessment (TEA) plays crucial role. Spatial or economic considerations may limit the scalability of certain technologies. For electrochemical DOC cell, the total cost can be broken down into four sectors; equipment cost and power cost for capture and release of CO_2 and ED, respectively. However, the contributions of the capture process, both for equipment and operation, are almost negligible compared with the costs for ED. This section will discuss the

main costs associated to CO_2 capture using these hybrid ED processes in terms of operating conditions and energy requirements [99].

3.4.1. BMPED cell

The BPMED cell involves two types of cells, incorporated into the CO_2 recovery cell and the alkali regeneration cell. Both cells are sandwiched between a BPM and a CEM. CEMs are polymeric membranes containing negative functional groups used to attract cations, while BPMs are composed of two types of ion-exchange membranes, a CEM and an AEM stacked together, to prevent ion leakage. AEMs are membranes with fixed positively charged chemical groups connected to the main polymer chains of the membrane [99].

An analysis was conducted on the total operational and equipment cost of BMPED cell that recovers CO_2 from bicarbonate solutions [100]. A 10-stack cell BMPED unit was used, with a stainless steel (SUS) electrode as the anode, platinum-coated titanium (Pt/Ti) cathode, commercial-grade BMP, and CEM. This unit was operated at a current density of 96 A/m^2 and a feed flow rate of 1.2 L/min, resulting in 30 % CO_2 recovery from bicarbonate solutions. The system was designed to treat 300 metric tons/h of CO_2 emission, which is equivalent to the amount emitted by a 400 MW coal-fired power plant. Assuming a unit cost for electricity at US$ 0.12, a minimum cost of US$ 180/ton CO_2 was achieved. The cost of electricity accounts for approximately 60 % of the total cost, while the cost of membranes accounts for 30 % of the total cost. To scale up the process, it was assumed that if the electric power price is reduced to US$ 0.06/kW h, the membrane costs are reduced by 1/10, and the current density is increased to 90 %, the minimum cost could be reduced to approximately US$ 70, which is competitive with the conventional amine chemical absorption process. The lifetime of the membranes can also be extended to reduce the total cost further (5 years for the base case). A group has reported a method for capturing CO_2 from bicarbonate solution using Neosepta BPM membrane with a thickness of 0.2 nm. This method can regenerate the captured CO_2 at the cost of US$ 38.07/ton CO_2, based on 2020 prices. During operation, the system consumes energy as low as 50 kJ/mol CO_2 and has a current efficiency of 91.2 % [101].

It is important to note that the CO_2 can be easily trapped in the membrane stack of BMPED, causing a “hot spot” that may damage the membrane surface and reduce its lifespan. To address this problem, a high-pressure BMPED stack was developed to eliminate CO_2 gas bubbles during the DOC process [81]. By increasing the pressure from 1.5 atm to 6 atm, the electrochemical energy was reduced from 471 kJ/mol CO_2 to 333 kJ/mol-CO_2. This high-pressure stack prevented the occurrence of “hot spots” and reduced energy consumption during the experimental process. The performance of the BPMED-based in situ mineralization method is also hindered by inorganic fouling in the alkaline pH range ($pH \geq 9$) when using real oceanwater as feed. However, it is believed that mineral scaling will not occur in the acidic channels due to their low pH ($pH \leq 4$). A report suggests that acid is the most effective choice for removing scale from the membrane, surpassing sparging O_2 and CO_2 [102]. To optimize BMED performance, it is advised to decrease the resistances of the AEM and CEM, as well as create thinner channels for the acid, base, and feed compartments [103]. Performance tradeoff curves can be used for BMPED to make comprehensive comparisons between different BMED operations and systems. It can also help in cost optimization if a cost model is provided. The performance tradeoff curve shows that the development of high-performance bipolar membranes can improve the overall performance of BMED to a moderate degree because multiple components govern the performance of a BMED process. For BMPED, higher temperature could improve the reaction rate, however, the thermal stability of the ion exchange membranes poses a limitation on high temperature processes. For instance, the commercial BMP cannot withstand temperatures higher than 40–60 °C for a long duration. Moreover, CO_2 solubility decreases at higher temperatures (up to 100 °C). This means that operating at high temperature is not yet practical.

3.4.2. ECE, EHL and Cl-mediated EC cells

From an economic point of view, CO_2 capture is only viable if the energy consumption of the capture is < 66 kJ/mol CO_2, whereas, electrochemical processes often have energy consumption greater than 300 kJ/mol CO_2 [74]. In terms of energy consumption, among the electrochemical DOC systems, EHL is more cost-effective approach for scale up design [37]. For example, BPMED consumes approximately 1400 kWh/ton CO_2 of electric energy, while ECE uses around 20,000 kWh/ton CO_2. Cl-mediated EC consumes about 699 kWh/ton CO_2, whereas EHL flow cell requires roughly 660 kWh/ton CO_2. While using acidified simulated seawater at pH ~4.7, a BPMED cell consumed ~155 kJ/mol CO_2 (~900 kWh/ton), which is approximately 1.5 times higher than that of the EHL flow cell [76]. Other than energy consumption, oxygen evolution reactions at BPMED and ECE require costly IrO_2 catalysts which hinder the potential for large-scale deployment when compared with electrolysis for hydrogen production. In contrast, EHL system utilizes oceanwater as electrolyte instead of chemical-based electrolytes. For highly efficient system for large-scale deployment, periodic cleaning and softening of oceanwater before injecting into EHL flow cell is perquisite for avoiding scale and $Mg(OH)_2$ and $Ca(OH)_2$ deposition at electrodes.

Compared to other electrochemical systems, the recently introduced Cl-mediated electrochemical DOC system costs US$ 56/ton CO_2 and is considered cheapest among all mentioned electrochemical systems so far [29]. This cost does not include the electrode replacement cost that also tends to be lower since only two electrodes are involved, while no membrane or redox couples are involved which demands more frequent replacement than the installed Bi/AgCl electrodes. Overall estimated cost for such electrochemical system is US$ 100/ton CO_2. By adding the cost of other systems such as oceanwater pumping, intake filtration, and CO_2 separation, the total process cost could reach up to US$ 2,000/ton CO_2 [76]. For deployment of electrochemical DOC systems at larger scale, future efforts are required to reduce pumping and degassing costs.

3.4.3. HFMC cells

A preliminary TEA was performed to determine the feasibility of scaling up of HFMCs-based DOC system to large DOC facility. Estimated capital and operating costs for a direct ocean capture HFMC plant that captures 980,000 ton/year of CO_2 was US$ 9,565 [86]. Cost analysis revealed that current DOC system is 16 times more expensive than DAC benchmarks due to the very low CO_2 removal rates. Main reason for low flux rate of CO_2 is the low concentrations of CO_2 in oceanwater. For this study, synthetic seawater with a CO_2 concentration of 110 ppm was used, which is significantly lower than the atmospheric CO_2 concentration of approximately 416 ppm recorded in 2019. Flux can be increased by optimizing different variables such as flow rate, temperature, membrane thickness, however these options are not sufficient to make a cost-effective DOC system. To increase CO_2 flux, one cost-effective option is to reduce the pH of oceanwater because reducing pH will release gaseous CO_2 and increase CO_2 flux. In doing so, the membrane cost will increase twice for lowering pH to one whole number that will account for the extra cost of locally treating oceanwater pH. Nevertheless, even after adding additional membrane cost, if oceanwater pH can be lowered from 8 to 5, the cost of the system can be reduced from US$ 9,565 to US$ 290/ton CO_2 value respectively. In this cost range (~US$ 300), this DOC technology may become competitive with state-of-the-art DAC system [86].

3.4.4. Additives-based mineralization approaches

Considering additives-based DOC processes, mineralization of oceanwater using steel slag worked at low energy consumption of 127 kWh/ton CO_2 which was calculated according to the mass of flue gas, and the total system cost coming from pumps, crusher, mixer and separator was estimated to be US$ 10.4/ton CO_2 [41]. CKD industrial waste and oceanwater as solvent was used in another DOC process. However, the cost per ton of captured CO_2 was not calculated. Nevertheless, it was suggested that a cement manufacturing plant or paper

mill that emits a large amount of CO_2 and uses $CaCO_3$ as a raw material present in close vicinity to the ocean would be very beneficial for this technology to be scaled up in more economic and eco-friendly way [42]. To further reduce the cost of DOC scaled up designs, they should be integrated with onshore desalination plants to take advantage of the installed water-handling facilities. The captured CO_2 can be injected directly from platforms into sub-surface geologic structures for long term sequestration or used as a feedstock for fuels or for commodity and specialty chemicals production.

The maritime transport cost is another factor in mineralization approach. It has been estimated that it might take 100 ships yearly to achieve a net carbon removal of approximately 1Gt of CO_2, with an energy consumption of 99.5 MJ/ton [67]. Recently, researchers advocated a sewage-delivered ocean alkalinity enhancement (SDOAE) approach to reduce transport costs [104]. Approximately 1,000 km^3 of wastewater (sewage) is generated and discharged worldwide annually. Sewage contains high concentration of organic acids which reduces the pH of sewage. Therefore, SDOAE approach can be used to transport strong alkalis, avoiding a significant amount of secondary precipitation (i.e., $CaCO_3$), that can further reduce the overall cost of DOC process [104]. The pH of seawater is typically not conducive to dissolving olivine and $CaCO_3$, but their dissolution can be facilitated by the SDOAE approach. This process increases the alkalinity of the water, which can be carried offshore by river plumes and ocean currents. Therefore, ocean alkalinity enhancement and carbon dioxide removal can be implemented on a large scale.

Mitigating membrane fouling and electrode poisoning in direct ocean capture (DOC) technologies involves several strategies. For membrane fouling, pre-treatment of seawater using filtration, chemical treatment, and UV light is essential, along with anti-fouling membranes enhanced through surface modification and hydrophilic properties. Operational strategies such as optimizing flow rate, backwashing, chemical cleaning, and controlling biofouling with biocides and coatings also play crucial roles [4]. To combat electrode poisoning, selecting resistant or alloyed materials, surface modification with protective coatings and catalyst layers, and operational strategies such as potential control, periodic regeneration, and proper electrolyte flow are effective [5]. Additionally, electrolyte management through regular purification and additives can prevent contaminants from affecting electrodes. Implementing these approaches improves the efficiency and longevity of DOC systems, promoting sustainable carbon capture from ocean water [4,5].

4. Comparison between DAC and DOC technologies

Direct Air Capture (DAC) is also attracting increased attention and financial investment from notable figures like Bill Gates and Elon Musk [105]. Compared to DAC, DOC is an even less explored territory. However, Equatic, Captura, and other companies are working to demonstrate the concept's feasibility with support from the Chan Zuckerberg Initiative, Gates Foundation, oil and gas companies, and the Advanced Research Projects Agency-Energy (ARPA-E). In this section, a comparison between DAC and DOC will be presented in terms of process design and energy demand, capture cost, land use and location, scalability, and potential for intensification.

4.1. Process design and energy demand

Conventional DAC technologies have traditionally relied on thermal amine-based scrubbing methods typically used to separate CO_2 from natural gas and hydrogen [106]. This method employs a chemical wet process, whereby liquid sorbents capture CO_2 and then release it through a temperature (100 °C–150 °C) or pressure (up to 10 kPa) swing (TS or PS) process. In DAC pilot and commercial plants, adsorptive solids or basic aqueous solutions are mostly used to capture CO_2 from atmosphere that requires relatively smaller footprint and could be powered by renewable energy such as solar, wind, and geothermal sources [24,32,45]. While this method has been tested on a large scale for CO_2 capture from industrial power plants and is a reliable technology, it has some weaknesses that remain as a challenging task for commercial application [107,108]. Firstly, the amine-scrubbing method is widely used for point source carbon capture, which still are attributed to 60 % of annual CO_2 emissions. Capturing carbon emissions from point sources involves an estimated thermal energy requirement of about 3.2–4.0 GJ/ton of CO_2 captured. This is equivalent to 89–112 million TJ of annual energy consumption, which accounts for about 13–17 % of the world's energy consumption [109,110]. However, using thermochemical-based capture in highly diluted CO_2 concentrations (0.04 % CO_2) requires more energy with a total 4.8–10.2 GJ of thermal energy per ton of CO_2 captured, which is not practically feasible [111]. Energy requirement is further increased for solvent DAC technology which is equivalent to either 8.81 GJ natural gas or 5.25 GJ natural gas coupled with 366 kWh of electricity. DAC can be considered as a "refinery for the sky" when it comes to energy. In the United States, refineries consume approximately about 880 TWh of energy per year. Assuming the same amount of energy is utilized for DAC and that each DAC facility requires about 300 MW of consistent energy to capture 1 $MtCO_2$/year, the same quantity of energy could be used to capture 370 $MtCO_2$/year. These figures demonstrate the possibility and difficulty of deploying DAC on an industrial scale from an energy perspective [112].

The energy efficiencies of thermodynamic-driven capture systems are subpar, typically ranging from 10 to 15 % due to inherent limitations within the system such as, high regeneration cost, degradation of adsorbents at higher temperatures as well as poor recyclability of adsorbent. Secondly, considering Gibbs free energy, regeneration process to spontaneously release CO_2 followed by the capture process requires entropic contribution by increasing temperature to compensate enthalpic contribution. Higher temperature for CO_2 release could also lead to sorbent degradation, resulting in slower CO_2 adsorption rates and low CO_2 capture efficiency [113]. However, high-grade (900 °C) heat demand of aqueous solution-based DAC could limit the options for heat source and increase the cost [15]. This scenario is expected to require more energy to capture and release CO_2 from these diluted sources and may impede the continued use of wet scrubbing in CO_2 capture systems. Furthermore, the widespread use of this method has been impeded by high-temperature/pressure that require significant costs to separate CO_2, as well as environmental issues associated with the use of corrosive amine derivatives as CO_2 sorbents [114].

For DOC, electrochemically-mediated carbon capture (EMCC) has been extensively studied as a viable alternative to amine-scrubbing carbon capture systems [111]. The primary distinction between EMCC and amine-scrubbing processes is that the entire capture and release processes are regulated by applying a bias or potential to an electrochemical device, instead of a TS/PS swing. Using the ED concept, in terms of energy utilization, DOC is considered favorable over DAC with a total usage of 1.3 kWh/kg (1,179kWh/ton) of CO_2 as compared to 1.54 to 2.45 kWh/kg (1,396.7 to 2,222.15 kWh/ton) in the case of DAC. Ideally, EMCC devices can combine with renewable energy to generate power for CO_2 capture. The modularity and portability features of ECCs facilitate direct air capture from any location, thereby effectively balancing the emissions and advancing the cause of carbon neutrality.

4.2. Cost, land use and geographical locality

Despite possessing the capability to capture high amounts of carbon, DAC technology remains prohibitively expensive and has yet to meet the necessary efficiency standards required to tackle the global carbon capture challenge. Particularly, at low atmospheric CO_2 concentrations of approximately 420 ppm, DAC implication would be more challenging and expensive with highest estimated cost to be between ~US$ 500 to 600/ton CO_2 which limits its prevalent implementation [115]. At these very low CO_2 concentrations, solvents or sorbents with strong binding

capabilities are required. As CO_2 binding capability is faster with strong base, therefore, for absorption, a chosen solvent should be a strong base. This binding demands a chemical shift process, which in turn requires more energy. Similarly, for adsorption, to saturate solid sorbent, a driving force is needed for regeneration and without that driving force more energy is needed to release the CO_2 from the sorbent. In doing so, larger surface area and efficient solid or liquid sorbent would be required which is the second largest factor after electricity in the capital cost of a DAC plant [116]. Carbon Engineering's sodium hydroxide-based operating plant places costs within the range USDUS$ 94–232/ton CO_2 [117]. The capital cost of constructing the Climeworks' Hinwil DAC system, which captures 900 ton CO_2/year was US$ 3–4 million which is the largest influencer of the levelized capture price of US$ 500–600 /ton of CO_2 [112].

To date, most prominent DOC approaches use electrochemical water-splitting to partition seawater into acidic and basic streams and then capturing of CO_2 from the acidic stream [76,80,81] (Fig. 4). For stand-alone ED-based DOC plant, estimated cost is 1,870to 2,50 US$/kg CO_2 which is 2 times more than Climeworks cost of DAC [24]. DOC cost could be reduced to 500US$/ton CO_2 if a desalination plant is located in close vicinity by utilizing infrastructure, but, that will reduce the CO_2 capture capacity to less than 100 kton/year of CO_2 [72]. Recent research has demonstrated use of fixed bed of sodium carbonate capsules for DOC purpose. Estimated cost of the designed DOC system was US$ 8,977.34/ton CO_2 which is not economically competitive compared to the DAC industrial target cost of 500 to 600 US$/ton [115].

In terms of geographical locality, DAC is not limited to locations with large, stationary CO_2 sources. In principle, it can be applied anywhere, although it would be ideal to have both an energy source and a CO_2 storage site nearby. This has several advantages: small-scale industries can continue to operate without the need for process modifications, CO_2-producing facilities that are located far away do not require extensive CO_2 transport infrastructure, DAC facilities can be co-located with renewable energy generation facilities to reduce transmission losses, and/or with CO_2 storage facilities to minimize transport costs and infrastructure. The location should also consider the land utilized, permeability of land, nearby air and noise pollution, and the discharge into local waterways. Whereas, designing a DOC system could be economical and smaller in size than a DAC system since it needs to process much less fluid volume, while DOC operating plants could be installed offshore and above CO_2 reservoirs under the seafloor that would not require valuable land space as well as reduce the cost of CO_2 transportation.

4.3. Scalability and intensification strategies

The primary industrial developers of DAC today are Carbon Engineering (Canada) and Climeworks (Switzerland). According to the IEA, as of 2022 there are 19 operational DAC plants worldwide with the potential to capture up to 0.01 $MtCO_2$/year [112,118]. Carbon Engineering is the first commercial entity to pursue solvent DAC technology. They use a potassium hydroxide solvent-based approach to their DAC technology coupled with a calcium caustic recovery loop. Carbon Engineering is currently building the largest DAC facility, called "STRATOS", with a capturing capacity of half a million of CO_2 annually and potential for scale-up to 1 million. It is expected that this plant will be operational by mid-2025 in Texas, USA. Climeworks is currently constructing the largest DAC and storage plant (Mammoth plant) in Hellisheidi, which will be designed to capture up to 36,000 tons of CO_2 annually and is planned to be operational by the middle of 2025 [22].

For DOC, there are no industrial plant operating yet, however, Captura, has launched the first DOC pilot plant off the coast of Newport Beach, CA in 2021 which is capable of capturing 100 tons of CO_2 per year using a system based on electrodialysis [82]. Although EMCC technology is technically underdeveloped, it does offer several potential benefits. These include safe operation in conditions of low pressure and ambient temperature, the ability to scale up the electrochemical device, and higher efficiency when compared to the thermochemical amine scrubbing method [83]. Particularly, EMCC technology can capture CO_2 emissions from small sources, including agriculture, forests, oceans, transportation, and residential areas where traditional methods are not feasible due to energy consumption and size. As this DOC application is still in its early stages of development, further research advances for practical demonstration are critical.

DOC stands to gain significant advantages from DAC. Firstly, DAC research frequently yields insights into materials, processes, and engineering that could be adapted to enhance the efficiency and effectiveness of DOC systems. DAC projects provide valuable lessons in scaling up carbon capture technologies, offering a roadmap for DOC initiatives to navigate challenges associated with large-scale deployment more effectively. Successful DAC projects can influence policy frameworks and attract increased funding for carbon capture efforts, benefiting both DAC and DOC initiatives. Lastly, as DAC gains acceptance, it has the potential to positively shape public perceptions of carbon capture technologies, including DOC, by highlighting their feasibility and benefits. Overall, fostering collaboration and knowledge exchange between the DAC and DOC communities holds promise for accelerating progress towards robust carbon capture solutions.

5. Conclusions and prospects for DAC and DOC

The application of both Direct Air Capture (DAC) and Direct Ocean Capture (DOC) for decarbonization strategies depends on a variety of factors including efficiency, scalability, environmental impact, and economic feasibility. Although DAC technologies offer versatile solutions to combat climate change, they face major challenges with respect to the energy consumption, cost-effectiveness, and scalability. LCA and TEA for DAC have so far relied on data from pilot or lab-scale processes, which are not representative of commercial-scale processes. Establishing scaling laws for emerging materials or technologies is necessary to accurately extrapolate LCA data to larger scales and evaluate the true potential to either combat climate change or support decentralized CO_2 production.

To improve the performance of DOC technologies, it is likely that the development of novel solvents and adsorbent materials with enhanced capture capacity, selectivity, and lower regeneration costs, will be required. The emergence of membranes as alternative capture solutions is also unclear given the lack of datasets and the experimental challenges to develop ultra-selective materials in such dilute conditions. In addition, the effectiveness of heat exchangers and auxiliary facilities is also currently limited while conducting optimization of networking processes, is of major importance to improve efficiency. At present most technologies developed are not mature enough to support large scale deployment and that the future of DAC, and current projects being developed and implemented. Given that no large-scale plants on the tens of megaton of CO2 captured per year are planned at present, and since the deployment of any large-scale plants may take at minima 5–10 years from the design phase to the full commissioning, the direct impact of DAC on climate mitigation also does not will not likely benefit the current climate actions over the next 10–15 years, unless supported by massive public investment.

Alternatively, DOC technologies have been shown to leverage the natural carbon cycle and can potentially mitigate ocean acidification while providing a source of sequestered carbon. Nevertheless, DOC technologies are currently much less mature than DAC ones, and equally face challenges, particularly related to the potential impacts on marine ecosystems and the scalability of the technology. Performing thorough techno-economic analysis and LCA is crucial to optimize CO_2 reductions, including as an example mangrove restoration. The potential of DOC to however help balance pH changes at large scale may represent a route to limit the degradation of extremely pH-dependent ecosystems, such as coral reefs. However, the scalability of the technology and need to pump

and dose extremely large amounts of seawater appears as a major bottleneck to the technology scale-up. Electrochemical ocean capture has improved CO_2 capture potential but scaling and efficiency improvements require further research particularly due to biofouling of exchangers during capture. The impact of DOC operations on biodiversity is also unclear and studies to address them both locally and at scale must be performed. Exploring the capture of CO_2 at different depths of the water column, particularly in anoxic conditions where lower biological matter concentrations may be present compared to surface waters.

The current climate actions require technologies and both technical and governmental choices able to lead to major abatement of carbon emissions. The implementation of both DAC and DOC is context dependent, including local environmental conditions, available resources, and the primary goals of the carbon capture project. In the broader context, although both DAC and DOC represent significant advancements in carbon capture technology and have potential, they are currently not sufficiently mature and continued research and development is needed. The implementation of DAC and DOC however as a mean to produce CO_2 locally for industrial applications appears much more realistic leading to a net-zero CO2 balance. The use of DAC and DOC may reduce the footprint of long-range CO2 transfer and act as a secondary mitigation pathway. Their integration into broader climate mitigation strategies may not represent a major outcome over the medium term but their implementation for decentralized CO_2 carbonates production may however find on the long-term, markets ready to invest.

Future work in the field of DAC and DOC could involve several avenues for further exploration and development. One promising direction is the optimization of both technologies for enhanced efficiency and cost-effectiveness, perhaps through the refinement of capture materials or process engineering techniques. Additionally, research efforts could focus on scaling up these technologies from pilot to industrial levels, addressing challenges related to infrastructure, energy requirements, and environmental impacts along the way. Collaboration between academia, industry, and policymakers could facilitate the implementation of large-scale DAC and DOC projects, while interdisciplinary studies could explore novel integration strategies with other carbon capture and renewable energy technologies. Furthermore, there is a need for continued monitoring and assessment of the environmental and socio-economic implications of widespread DAC and DOC deployment to ensure their long-term sustainability and effectiveness in combating climate change.

CRediT authorship contribution statement

Omnya Al Yafiee: Writing – original draft, Formal analysis, Data curation. **Fatima Mumtaz:** Writing – original draft, Formal analysis, Data curation. **Priyanka Kumari:** Writing – review & editing, Supervision, Formal analysis. **Georgios N. Karanikolos:** Writing – review & editing, Supervision. **Alessandro Decarlis:** Writing – review & editing, Data curation. **Ludovic F. Dumée:** Writing – review & editing, Supervision, Methodology, Data curation, Conceptualization.

Declaration of competing interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Data availability

Data will be made available on request.

Updated Buildings Sector Appliance and Equipment Costs and Efficiencies

March 2023

Independent Statistics and Analysis
U.S. Energy Information Administration

www.eia.gov
U.S. Department of Energy
Washington, DC 20585

The U.S. Energy Information Administration (EIA), the statistical and analytical agency within the U.S. Department of Energy (DOE), prepared this report. By law, our data, analyses, and forecasts are independent of approval by any other officer or employee of the U.S. Government. The views in this report do not represent those of DOE or any other federal agencies.

March 2023

Updated Buildings Sector Appliance and Equipment Costs and Efficiencies

Energy used in the residential and commercial sectors provides a wide range of services, including heating, cooling, lighting, refrigeration, cooking, and numerous other end uses. The U.S. Energy Information Administration (EIA) conducts two buildings-sector surveys—the *Residential Energy Consumption Survey* (RECS) and the *Commercial Buildings Energy Consumption Survey* (CBECS)—that provide information on the equipment stock and energy consumption within existing buildings. However, these surveys do not directly gather other information that we need to project future energy consumption, such as equipment cost information or nameplate efficiency ratings.

The Residential Demand Module (RDM) and the Commercial Demand Module (CDM) of the National Energy Modeling System (NEMS) use equipment cost and performance technology menus that represent competing options for most of the major end uses. The contracted reports in Appendixes A–D provide the information basis on which these menus can be built, focusing on cost and efficiency characterizations across equipment and fuel types. Previous editions of the *Annual Energy Outlook* (AEO) used similar contracted reports.

Multiple equipment classes and types are represented in these menus so that the projected equipment stock can change over time in response to fuel prices and other factors that affect equipment choice, such as appliance standards. The equipment menus interact with other NEMS parameters to determine market shares, equipment efficiency levels, cost estimates, and equipment interactions,[1] and they are used to translate service demand into energy demand.

Appendixes A and B constitute one set of reports that characterizes most major residential equipment and commercial heating, cooling, and water heating equipment. Appendix A is used in developing Reference case projections, while Appendix B is used in developing advanced technology cases.[2] These assumptions will be developed and implemented during the AEO2024 cycle.

Appendixes C and D constitute another set of reports that characterizes residential and commercial lighting, as well as commercial ventilation and refrigeration equipment. Appendix C is used in developing the Reference case, while Appendix D is used in developing advanced technology cases. These assumptions were developed and implemented during the AEO2023 cycle.

When referencing the contracted reports in Appendixes A, B, C, and D, you should cite them as reports by Guidehouse and Leidos, prepared for the U.S. Energy Information Administration.

[1] Examples of equipment interactions are solar water heaters that supplement traditional water heaters, clothes washers that reduce the need for clothes drying, and water heaters that provide dishwashers and clothes washers with heated water.

[2] In addition to the Reference case, we also develop sensitivities to explore different assumptions for the cost and performance of future technologies. For the more optimistic cases, some equipment achieves lower life-cycle costs through improved efficiency or lower upfront costs, or both. The contracted reports provide a base case and an advanced case for modeling the AEO Reference case along with the more optimistic cases. We use the advanced case assumptions to develop side cases for AEO reports that include such analyses.

Objective

The objective of this study is to develop baseline and projected performance/cost characteristics for residential and commercial end-use equipment.

- Installed base in 2012 and 2018 (for commercial products) or 2015 and 2020 (for residential products) and current market (2022)
  - Review literature, standards, installed base, contractor, and manufacturer information
  - Provide a relative comparison and characterization of the cost/efficiency of a generic product
- Forecast of technology improvements that are projected to be available through 2050
  - Review trends in standards, product enhancements, and Research and Development (R&D)
  - Project impact of product improvements and enhancement to technology

The performance/cost characterization of end-use equipment developed in this study will assist EIA in projecting national primary energy consumption.

Methodology

Return to Table of Contents

Input from industry stakeholders, including government, R&D organizations, and manufacturers, was used to project product enhancements concerning equipment performance and cost attributes.

- Technology forecasting involves many uncertainties.
- Technology developments impact performance and cost forecasts.
- Varied sources ensure a balanced view of technology progress and the probable timing of commercial availability.
- Only currently published efficiency standards and regulations are considered when predicting technology developments; unpublished future regulatory action is not predicted.
- All costs are shown in 2022 dollars (2022$).
- Ranges, when given, represent the span of typical values for a given parameter (e.g., installed cost for equipment meeting the federal standard) not the highest and lowest available on the market.

Definitions

Return to Table of Contents

The following tables represent the current and projected efficiencies for residential and commercial building equipment ranging from the installed base in 2012 and 2018 (for commercial products) or 2015 and 2020 (for residential products) to the highest efficiency equipment that is expected to be commercially available by 2050, assuming incremental adoption. Below are definitions for the terms used in characterizing the status of each technology.

- Installed Base: Efficiency values are for those units installed and "in use" in that year. Cost values are for the typical new unit sold in that year.
- Current Standard: The minimum efficiency (or maximum energy use) that is required (allowed) by current U.S. Department of Energy (DOE) standards, when applicable.
- ENERGY STAR: The minimum efficiency that is required (or maximum energy use allowed) to meet the ENERGY STAR criteria, when applicable. The performance data that are presented are representative of certified products that just meet current ENERGY STAR specifications.
- Typical: Efficiency and cost values are for the average, or "typical," product being sold in the particular timeframe. This may represent either the shipments-weighted average product performance or the most common product on the market.
- High: Efficiency and cost values are for the product with the highest efficiency available in the particular timeframe.

Market Transformation

Return to Table of Contents

The market for the reviewed products has changed since this analysis was previously conducted.[1] These changes are noted and reflected in the efficiency and cost characteristics.

- In some categories the typical new product purchased today is more efficient than the average product in the installed base in 2012 (commercial) or 2015 (residential):
  - Residential sector: boilers, central air conditioners, room air conditioners, gas-fired furnaces (North), gas-fired furnaces (Rest of Country), oil-fired furnaces, electric resistance furnaces, heat pump water heaters, gas-fired instantaneous water heaters, natural gas cooktops, natural gas ovens, refrigerator-freezers, freezers, clothes dryers, clothes washers, and dishwashers
  - Commercial sector: gas-fired furnaces, oil-fired boilers, commercial rooftop heat pumps, commercial ground-source heat pumps, gas-fired instantaneous water heater, natural gas and electric ranges, griddles, and ovens
- More stringent Federal standards have taken effect for the following products:
  - Gas-fired and oil-fired boilers in 2021
  - Rooftop air conditioners and rooftop heat pumps in 2018
- Federal standards are slated to take effect in the coming years for the following products:
  - Central air conditioners, residential air-source heat pumps, gas-fired furnaces, oil-fired furnaces, gas-fired boilers, oil-fired boilers, rooftop air conditioners, and rooftop heat pumps in 2023
  - Portable air conditioners in 2025
- ENERGY STAR continues to raise the bar with revised criteria for:
  - Central air conditioners, residential air-source heat pumps, rooftop air conditioners, rooftop heat pumps, residential water heaters, and dishwashers in 2023

Note: The previous analysis is available in the EIA Technology Forecast Updates (2018) report.

DATA	2015	2020	2022				2030		2040		2050	
	Installed Base	Installed Base	Current Standard	Typical	ENERGY STAR (North) V. 4.1	High	Typical	High	Typical	High	Typical	High
Typical Input Capacity (kBtu/h)[1]	80	80	80	80	80	80	80	80	80	80	80	80
AFUE (%)	80	80	80	90	95	99	95	99	95	99	95	99
Electric Consumption (kWh/y)[2]	374	374	386	636	631	725	631	725	631	725	631	725
Average Life (y)[3]	17	17	17	17	17	17	17	17	17	17	17	17
	26	26	26	26	26	26	26	26	26	26	26	26
Retail Equipment Cost (2022$)	1,300	1,300	1,080	1,200	1,220	1,390	1,220	1,390	1,220	1,390	1,220	1,390
Total Installed Cost (2022$)	2,880	2,880	3,690	4,130	4,150	4,320	4,150	4,320	4,150	4,320	4,150	4,320
Annual Maintenance Cost (2022$)	60	60	120	130	130	130	130	130	130	130	130	130

1. Typical input capacity is represented in terms of thousand British thermal units (kBtu) per hour (i.e., kBtu/h).
2. Electric consumption, represented in terms of kilowatt hours per year (kWh/y), accounts for the electricity consumption of components such as the furnace fan, draft inducer, and the ignitor. In some high efficiency products, this component also includes auxiliary equipment, such as condensate pumps and heat tape.
3. In the Residential Furnaces EERE 2022 Notice of Proposed Rulemaking (NOPR) Technical Support Document (TSD), an average lifetime of 22.5 years is calculated for gas-fired furnaces (North). Lifetime range was calculated using the Weibull Distribution in the Residential Furnaces EERE 2022 NOPR.

Note:
Models on the market can be either weatherized or non-weatherized. The majority (74%) are non-weatherized, and the values in the table use only non-weatherized data.
Electric consumption and cost values for 2022 and beyond are for a national sample and use the Residential Furnaces EERE 2022 NOPR Life-Cycle-Cost (LCC) spreadsheet.
Electric consumption and costs for the 2030, 2040, and 2050 high values are estimated based on the maximum-efficiency level analyzed in Residential Furnaces EERE 2022 NOPR, which is 98% annual fuel utilization efficiency (AFUE).
The current standard went into effect in November 2015.
ENERGY STAR V. 4.1 went into effect in February 2013.
The range for average life represents the span of typical values.

The range for average life represents the span of typical values.

U21806-MNSC-CE-0771-Att 4

Final

Residential Gas-Fired Furnaces

Return to Table of Contents

- Current Federal standards for non-weatherized gas furnaces:
  - AFUE ≥ 80%
- ENERGY STAR V. 4.1 criteria for gas furnaces:
  - South: AFUE ≥ 90%
  - North: AFUE ≥ 95%
  - Furnaces must be equipped with electronically commutated fan motor and have less than or equal to 2.0% air leakage
- Most efficient unit currently available: 99.0% AFUE. The current market is nearly evenly split between non-condensing units (AFUE≤82%) and condensing units (AFUE≥90%).
- The maximum AFUE for non-condensing gas furnaces is 82%; above this level, the potential for exhaust gas condensation increases. This condensate is corrosive and requires cost restrictive corrosion resistant venting.
- High-efficiency condensing furnaces typically have high-grade stainless steel (AL 29-4C) heat exchangers.
- Many condensing furnaces are available as direct vent and sealed combustion systems, which do not use room air for combustion, but instead draw combustion air directly from outdoors.
- Depending on the location of the home, piping materials in use, and other considerations, condensing furnaces may need an acid neutralizer and/or lift pump for the condensate.
- Furnaces may contain permanent split capacitor (PSC) fan motors or electronically commutated motors (ECMs). The type of motor affects the electrical consumption of the furnace as well as the seasonal energy efficiency ratio (SEER) / energy efficiency ratio (EER) of the associated air conditioner.
  - The 2016 Energy Conservation Standards for Residential Furnace Fans Final Rule requires that all furnaces use ECM fans.
  - Most non-weatherized gas furnaces employ ECMs and can fully modulate rather than cycling on and off. Because they modulate, there is an increase in total fan-on time.

1. Electric consumption accounts for the electricity consumption of components such as the furnace fan, draft inducer, and the ignitor. In some high efficiency products, this component also includes auxiliary equipment, such as condensate pumps and heat tape.
2. Lifetime range was calculated using the Weibull Distribution in Residential Furnaces EERE 2011.

Note:
The current standard went into effect in May 2013.
ENERGY STAR V. 4.1 went into effect in February 2013.
Ranges represent the span of typical values for a given parameter.

Residential Oil-Fired Furnaces

Final

Return to Table of Contents

- Current Federal standards:
  - AFUE ≥ 83%
  - ≤ 11 watts of electrical power when in standby and off modes (non-weatherized models only)
- ENERGY STAR V. 4.1 criteria: AFUE ≥ 85%
- Since the latent heat content of oil is lower than that for either propane or natural gas, oil-fired appliances can typically operate at a higher AFUE rating than comparable gas-fired appliances before condensation issues arise.
- Most efficient unit currently available: 96.7% AFUE – condensing units with tiny market share (<1%), due to market acceptance issues.
- Condensate from condensing oil furnaces is typically even more corrosive than that of gas-fired systems due to the higher sulfur content in fuel oil. Hence, condensing oil furnaces also likely require the use of an acid neutralizer.
- Oil-fired furnaces, like gas-fired furnaces, achieve condensing conditions through the use of a secondary heat exchanger. Typically, these secondary heat exchangers use a high-grade stainless steel (AL 29-4C).
- Sooting is an issue for all oil-fired appliances, but secondary heat exchangers, with their narrow passages, are even more prone to be plugged by soot. Because of this, condensing oil furnaces typically require frequent cleaning and maintenance.

1. The 2020 AFUE is estimated based on EERE 2022 preliminary analysis, which estimates that gas-fired boilers with the highest market share in 2020 have an AFUE of 95%.
2. The 2030, 2040, 2050 projections are estimated based on the EERE 2022 preliminary analysis, which notes that majority of the market is expected to be condensing, if new standards are not implemented. The EERE 2022 preliminary analysis estimates a minimum efficiency of 95% AFUE for condensing units.
3. Electric Consumption accounts for the electricity consumption of auxiliary electrical components including circulating pump, the boiler pump (condensing boilers only), the draft inducer (if present), and the ignitor. It also accounts for the electricity consumption of auxiliary equipment such as a condensate pump and heat tape, which are sometimes installed with higher efficiency boilers. Additionally, it accounts for the additional cooling load due to heat loss from the boiler and water heater as a result of water heating during the cooling season.
4. Maintenance cost is the routine annual cost to the consumer of general maintenance for product operation. Maintenance cost is higher for condensing boilers for the inspection of condensate system and replacement of condensate neutralizer filter.

Note:
The current standard went into effect in January 2021.
ENERGY STAR V. 3.0 went into effect in December 2013.
Water boilers considered. Steam boilers also exist but make up a small percentage of the market.
The range for average life represents the span of typical values.

Residential Gas-Fired Boilers

Return to Table of Contents

- Federal standard for gas-fired hot-water boilers (more common than steam):
  - AFUE ≥ 84%
  - Standard went into effect on January 21, 2021
- ENERGY STAR criteria: AFUE ≥ 90%
- Most efficient gas-fired boiler available: 96.4% AFUE
- Gas-fired boilers have lost market share to furnaces and heat pumps over the past 30 years.
- U.S. gas hot water boiler sales are split approximately 60/40 between condensing and non-condensing.[1] Condensing boilers typically have heat exchangers made of stainless steel, and non-condensing boilers typically have heat exchangers made of cast iron.
- Typically, condensing boilers are low-mass in construction with modulating burners, variable-speed inducer fan systems or sealed powered direct-vent combustion, multiple sensor technologies, and electronic ignition and control.
- Due to incentives and market pressure, the U.S. boiler industry has been shifting towards also providing condensing boilers. Most of these boilers are private-labeled products sourced from Europe, where the hydronic market is much bigger and condensing appliances are much more common and/or required by law.
- Most value-added components for condensing boilers are sourced abroad, even when the condensing boiler is assembled in North America (e.g., heat exchanger, gas valve, burner, sensors, and/or controls).

Residential Oil-Fired Boilers

Return to Table of Contents

- Federal standard for oil-fired hot-water boilers (more common than steam):
  - AFUE ≥ 86%
  - Standard went into effect on January 21, 2021
- ENERGY STAR criteria: AFUE ≥ 87%
- Most efficient oil-fired boiler available: 88% AFUE
- Since the latent heat content of oil is lower than that for either propane or natural gas, oil-fired appliances can typically operate at a higher AFUE rating than comparable gas-fired appliances before condensation issues arise.
- Oil boilers have heat exchangers made of cast iron or steel.
- No condensing oil-fired boilers currently exist in the U.S. market. The high sulfur content in fuel-oil causes heat exchanger fouling if the flue gases from an oil-fired boiler were to condense. As a result, condensing oil-fired boilers would require more frequent maintenance and repair, if installed.

Residential Electric Resistance Furnaces

Return to Table of Contents

- Federal standards for electric furnaces:
  - AFUE ≥ 78%
  - Standby and off mode power consumption ≤ 10 watts
- According to preliminary Residential Energy Consumption Survey (RECS) data released May 2022, electric central warm-air furnaces are the main source of space heating in approximately 17.5 million U.S. homes or about 14%.
- Electric furnaces range in capacity from 10 to 25 kW (34 to 85 kBtu/h), with 20 kW (68 kBtu/h) being the typical for units on the market.
- Electric resistance furnaces are considered near 100% efficient because there is no flue heat loss, and any jacket losses are contained within the home.
  - ASHRAE Standard 103, the test method for furnaces incorporated by reference into the federal test procedure, specifies that for electric furnaces AFUE = 100 – 1.7 x jacket losses. Jacket losses can be determined either through testing or assumed to be 1%. Thus, the minimum AFUE of electric furnaces is 98.3%.

1. Assumes similar lifetime to Electric Furnaces on the basis that both products have heating elements that burn out and lead to product failure.
2. The lower bound of the equipment costs represents the average retail price listed at the typical capacity for electric baseboard heaters through a retailer website. The upper bound represents the average retail price for compact recessed electric wall heaters at the same capacity.
3. Range represents the estimated minimum and maximum installation costs.
4. Maintenance costs are negligible.

U21806-MNSC-CE-0771-Att 4

Final

Residential Electric Resistance Unit Heaters

Return to Table of Contents

- Electric resistance unit heaters include electric wall and baseboard heaters. Plug-in space heaters are not included.
- There are currently no federal efficiency requirements for electric resistance unit heaters.
- According to preliminary RECS data released May 2022, electric resistance unit heaters are the main source of space heating in approximately 8.25 million U.S. homes or about 7%.
- Electric heaters range in capacity from 500 to 2,500 watts (1.7 to 8.5 kBtu/h), with 1,500 watts (5.1 kBtu/h) being the most typical for units on the market.
- Electric resistance heating is considered 100% energy efficient; all incoming electric energy is converted to heat.

Residential Central Air Conditioners

Final

Return to Table of Contents

- The previous standards took effect in 2015; amended standards for all product classes went into effect in January 2023.
  - Amended standards are based on new metrics (SEER2, EER2).
  - SEER2 values are generally expected to be lower than SEER because a higher external static pressure is required during testing, which reduces measured performance.
- Systems installed in the Southwest (CA, AZ, NM, and NV) must also meet an EER standard that varies by cooling capacity and system configuration.

	830	630	630	640	640	750	640	750	640	750	640	750
Annual Maintenance Cost (2022$)[3]	0	0	0	0	0	0	0	0	0	0	0	0

1. RAC EERE 2022 NOPR has analysis for combined energy efficiency ratio (CEER) of 16 Btu/Wh, which represents variable speed room air conditioners. However, maximum CEER identified in DOE's Compliance Certification Database (CCD) in August 2022 was 15.7 Btu/Wh. Accordingly, the high CEER is estimated to be 15.7 for 2022 and beyond. Cost values for a representative unit with a CEER of 16 Btu/Wh were used.
2. The 2030, 2040, 2050 projections are estimated based on RAC EERE 2022 NOPR, which notes that in the absence of no new standards, room air conditioners with a CEER of 12 Btu/Wh are expected to have the maximum market share.
3. Maintenance costs are negligible per RAC EERE 2011 and RAC EERE 2022 NOPR.

Note:
All values are for the most common product class, Product Class 3 (without reverse cycle, with louvered sides, and 8,000 to 13,999 Btu/h).
The current standard went into effect in June 2014.
ENERGY STAR V. 4.2 went into effect in October 2015.
Ranges represent the span of typical values for a given parameter (for example, installed cost for equipment meeting the federal standard) not the highest and lowest available on the market.

Residential Room Air Conditioners

Final

Return to Table of Contents

- Analyzed the most common type of room air conditioners: louvered sides (window air conditioners) without reverse cycle and having cooling capacity of 8,000–13,999 Btu/h (DOE Product Class 3).
- Federal standards for Product Class 3:
  - CEER ≥ 10.9 (beginning June 1, 2014)
- CEER incorporates energy use in cooling mode and standby and off modes.
- ENERGY STAR V. 4.2 criteria for Product Class 3:
  - CEER ≥ 12.0 (effective October 26, 2015)
- Efficiency improvements in room air conditioners are attained by:
  - Higher efficiency compressor and fan motors (including variable speed motors), and
  - An increased heat transfer area in the evaporator and condenser using larger heat exchangers, finer fin spacing, micro-channel heat exchangers, and similar design options.

1. All values are for the average capacity for single-duct and dual-duct portable air conditioners available on the market.
2. CEER is calculated for typical capacity using the equation provided in PAC EERE 2020.
3. Installation and maintenance costs are negligible.
4. The 2022 Typical estimates are based on PAC EERE 2020, which estimated majority of the market to be at EL1 in 2022 for the no-new standards case, which translates to a CEER of 5.5 for this analysis.
5. All High values are based on the most-efficient models available in the market, as specified in PAC EERE 2020.

Note:
A final rule for portable air cleaners published in January 2020 with an effective date of January 2025.
Costs are interpolated from the costs presented in PAC EERE 2020.
Range for lifetime represents typical values.

Residential Swamp Coolers

Final

Return to Table of Contents

- Evaporative cooling (i.e., "swamp coolers") is a technology that takes advantage of water evaporation to cool incoming air. Energy is required to change water from a liquid to a vapor (i.e., the heat of vaporization), and in doing so, temperature of the air is reduced. Evaporative cooling is best suited for hot, dry climates.
- Swamp coolers come in a variety of different configurations, including centrally ducted units that are mounted outside a building or roof; window evaporative coolers that are window-mount units that pull in warm outdoor air, pass it through wet media to remove heat, and blow out the cooled air; or portable plug-in units. Window units were considered for this analysis due to the high model share count on distributor websites.
- The U.S. Environmental Protection Agency (EPA) has cautioned against using swamp coolers in wildfire-impacted areas in smoky conditions because it can result in more smoke bring brought inside.
- Swamp coolers are not a DOE-covered product.
- Swamp cooler metrics include power of the fan/blower, measured in horsepower (hp), and air flow rate, measured in cubic feet per minute (CFM).

1. Values shown are for split-system units in the 36 kBtu/h (3-ton) size class. Costs and efficiency levels are for "blower-coil" systems, meaning they include a blower. Note coil-only systems were analyzed for residential central air conditioners, which is why the "High" SEER levels are higher for heat pumps than for air conditioners.
2. In 2023, new energy conservation standards for Residential Central Air Conditioners and Heat Pumps took effect. The new standards specify different metrics for Air-Source Heat Pumps (SEER2 and heating seasonal performance factor 2 (HSPF2)). SEER to SEER2 and HSPF to HSPF2 conversions were determined using the RESNET website.
3. Annual maintenance include preventative maintenance and services provided by HVAC professionals for maintaining product operation. Examples include, calibrate and level thermostat, clean filters, clean indoor and condenser coil, flush/treat condensate drain with anti-algae, inspect condenser coil, monitor operating pressure of refrigerant, inspect fan blade, etc.
4. High costs derived from developing a cost-efficiency curve between retail/installed costs and SEER.

Note:
The previous standard went into effect in January 2015. The current standard went into effect in January 2023.
ENERGY STAR V. 5.0 went into effect in September 2015. ENERGY STAR V. 6.1 went into effect in January 2023.
Ranges represent the span of typical values for maintenance costs.
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (15.88, 2, 1).

U21806-MNSC-CE-0771-Att 4

Residential Air-Source Heat Pumps

Final

Return to Table of Contents

- The previous standards took effect in 2015; amended standards for all product classes went into effect in January 2023.
  - Amended standards are based on new metrics (SEER2, EER2, HSPF2).
  - SEER2 values are generally expected to be lower than SEER because a higher external static pressure is required during testing, which reduces measured performance.
- High efficiency cooling does not necessarily correlate with high efficiency heating. The range of SEER–HSPF combinations is very broad.
- Heat pumps are generally sized to meet the cooling load of the house. When the heating load exceeds heat pump heating capacity, electric resistance heat is used to supplement.
- Variable-speed compressors improve efficiency of heat pumps by reducing cyclic losses and by operating above their nominal speed, boosting heating capacity, and reducing the need for supplementary electric resistance heat.
- In addition to meeting the SEER2 and HSPF2 requirements, air source heat pumps must demonstrate low ambient performance to earn the Cold Climate designation by meeting the following:
  - Coefficient of Performance (COP) at 5 degrees Fahrenheit (°F) ≥ 1.75, measured in accordance with Appendix M1 $H4_2$ test
  - Percent of Heating Capacity at 5 °F ≥ 70% of that at 47 °F, with the 5 °F capacity measured per Appendix M1 $H4_2$ test and the 47 °F capacity measured as the nominal heating capacity per Appendix M1 (i.e., from the Appendix M1 $H1_N$ test for units having a variable-speed compressor where the compressor speed shall be the maximum speed that the system controls would operate at 47 °F, otherwise from the Appendix M1 $H1_2$ test)
  - Perform a controls verification procedure (CVP) to confirm that the above performance metrics measured at the Appendix M1 low ambient test point at 5 °F are achieved by the native controls operating as they would in a customer's home

U21806-MNSC-CE-0771-Att 4

Residential Central Air Conditioners and Air-Source Heat Pumps

Final

Return to Table of Contents

- Principal energy efficiency drivers for central air conditioners and heat pumps:
  - Heat exchanger (surface area, number of tube rows)
  - Compressor (type and single-stage vs. two-stage vs. variable-speed operation)
  - Fan motor choices (PSC vs. ECM fan motors on inside and outside)
  - Control choices (i.e., piston, thermal, and electronic expansion valves)
- When the heat pump or air conditioner's capacity exceeds the heating or cooling load, the unit starts and stops more frequently, causing wear and tear on the components and an overall loss of efficiency. Multi-stage and/or variable-speed compressors can help, as does sophisticated refrigerant management.
- Typical high-efficiency unit (≥ 16 SEER) has very large heat exchanger, ECM evaporator fan motor, and two-stage scroll compressor.
- Variable-speed compressor technology typically leads to a significant SEER boost, making possible high-SEER condensing units with smaller heat exchangers, and thus, smaller enclosures.
- Efficiency levels > 21 SEER made possible through combining existing large heat exchangers with variable-speed compressors, ECM fan motors, and electronic expansion valves.

Residential Ductless Mini-Split Air-Source Heat Pumps

Return to Table of Contents

- Ductless systems can be useful in "spot cooling" certain high-use areas of a home, such as a living room, bedroom, or office.
- Mini-split heat pumps are generally more efficient (often > 20 SEER) and smaller in cooling capacity (often ≤ 24 kBtu/h) compared to split-system heat pumps.
  - A mini-split heat pump could be equal in capacity and efficiency to a split-system heat pump as there are no inherent design changes between split-system and mini-split heat pumps, aside from the ductwork. Mini-split heat pumps tend to be more efficient and smaller in capacity due to their prevalence for spot cooling, but the same technologies are used between the two product categories.
- Due to the similarities in design, cost estimations were determined based on smaller capacity (24 kBtu/h) split-system heat pumps and Gordian's RSMeans Data – Building Construction Costs 2023. Efficiency data was analyzed using the AHRI directory, which provides disaggregation of data on the basis of ducted and ductless heat pumps.
- Annual maintenance covers the same services identified for air-source heat pumps.

Total Installed Cost (2022$)	14,060	14,880	14,230	14,880	14,880	15,940	14,880	15,940	14,880	15,940	14,880	15,940
	22,290	23,120	22,470	23,120	23,120	24,170	23,120	24,170	23,120	24,170	23,120	24,170
Annual Maintenance Cost (2022$)	90	90	90	90	90	90	90	90	90	90	90	90

1. COP values listed are assessed at a "ground loop" test condition, which is representative of closed loop ground source heat pumps (GSHP) operating conditions. However, DOE sets standards at a "water loop" test condition. The AHRI directory lists COP ratings at both sets of test conditions and is used to convert between them where necessary.
2. EER values listed are assessed at a full-load "ground loop" test condition, which is representative of closed loop GSHP operating conditions. However, DOE sets standards at a full-load "water loop" test condition. The AHRI directory lists EER ratings at all sets of test conditions and is used to convert between them where necessary.

Note:
Residential and commercial GSHPs are very similar - the main difference in data presented is the different capacity (3-ton vs. 4-ton) and slightly higher installation costs for commercial GSHP. DOE does not distinguish between residential and commercial units in its regulations.
Current standards went into effect on October 9, 2015. COP and EER ratings are converted from the “water loop” test condition to “ground loop.”
ENERGY STAR V. 3.2 went into effect January 1, 2012.
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay parameters: (17.04, 1.64, 1).

Residential Ground-Source Heat Pumps

- Heating COP does not correlate with cooling EER.
- The ENERGY STAR criteria for water-to-air ground-source heat pumps are:

Type	Heating COP	Cooling EER
Closed Loop	3.6	17.1
Open Loop	4.1	21.1
Direct Expansion	3.6	16

- The most common GSHP is a closed-loop system in which water or an anti-freeze solution is circulated through plastic pipes buried underground. Open loop systems that employ ground water or surface water (e.g., open well, pond, lake) are used in some parts of the country, but water supply and water quality issues impose limitations on such applications.
- Installation cost is for a closed loop system and includes necessary accessories. The ground loop heat exchanger represents a majority of the installation cost. Installed costs for these systems vary widely.
- Variable speed ECMs improve performance on high-end models.

U21806-MNSC-CE-0771-Att 4

1. Annual electric use accounts for the electricity consumption of components such as the heat pump fan.

Note:
Ranges represent the span of typical values observed in the market.

U21806-MNSC-CE-0771-Att 4

Residential Natural Gas Heat Pumps

Final

Return to Table of Contents

- Residential natural gas heat pumps are not currently subject to DOE regulations. The California Energy Commission's (CEC) Title 24, Part 6 Section 112 does indicate cooling efficiency requirements for natural gas heat pumps.
- Natural gas heat pumps are much more popular in other parts of the world, such as Europe. Gas-fired cooling equipment currently comprises less than 1% of the residential air conditioning/heat pump market in the U.S.
- Currently, Robur is the predominant manufacturer of residential-sized natural gas heat pumps with sales operations in the U.S.. Robur units are 5-ton nominal cooling capacity, a size typically associated with larger homes. Since only one product is available, no mid-level or high efficiency categories are included in this analysis.
- The data represents air-source absorption heat pumps. Gas engine-driven vapor compression heat pumps are available in other parts of the world; York formerly offered the Triathlon gas engine-driven heat pump in the U.S. It is possible to couple either technology to the ground (ground-source) rather than the atmosphere (air-source).
- The absorption heat pump is a gas-fired, ammonia-water absorption cycle, combined with a high-efficiency low-pressure boiler integrated into one outdoor unit.
- The cooling efficiency of a gas-fired air-source absorption heat pump is considerably lower than for an electric air-source heat pump. Heating efficiency of an air-source heat pump (electric or gas-fired absorption) decreases as outdoor temperature decreases; however, the gas-fired absorption heat pump recovers waste heat from the combustion process to improve heating efficiency.

1. For 2015, assumed EPA default efficiencies, which were used by EPA to approximate the efficiency of stoves before the 2015 EPA rule required efficiency testing.
2. For 2020, assumed same efficiencies as estimated for 2022 given the most recent EPA rule went into effect in May 2020.
3. The 2022 High value is the highest EPA certified efficiency. The 2022 Typical value is the average of EPA certified efficiencies.
4. For 2030-2050, it is assumed that the same conditions as current would persist because no impending efficiency requirements are expected from EPA, given recency of 2020 rulemaking and current market factors.
5. Efficiency includes combustion and heat transfer efficiency and is based on the higher heating value (HHV) of the fuel.
6. Installed costs include the cost of hearth and stainless-steel chimney liner - materials and labor.
7. For catalytic stoves, annual maintenance cost includes periodic cost of replacing the catalytic combustor.

Note:
The range for average life represents the span of typical values.

Residential Cordwood Stoves

Final

Return to Table of Contents

- Residential cordwood stoves that must meet EPA particulate limits fall into two broad classes based on whether they use a catalyst for air treatment. Catalytic wood stoves use a catalytic combustor to reduce emissions from the combustion air. Non-catalytic wood stoves use baffles and introduce secondary air above the flames to enable more complete combustion and reduce emissions.
- In 2015, EPA published an update to its New Source Performance Standards (NSPS), decreasing the emissions limit (previously set by 1988 EPA rule) to 4.5 grams per hour (g/h) for both catalytic and non-catalytic stoves. The new rule did not institute efficiency standards but required that manufacturers test and certify the efficiency of their stoves. This standard took full effect on January 1, 2016.
- In 2020, the NSPS limit for new room heaters was lowered to 2.5 g/h if tested with cord wood.
- Prior to the 2015 rule, manufacturers could either submit efficiency data from laboratory testing or certify with the default efficiency value designated by EPA. EPA's default efficiency values were 63% for non-catalytic wood stoves and 72% for catalytic wood stoves. Under this system, few manufacturers submitted efficiency test data to EPA.
- Multiple test standards are commonly used to assess stove efficiency, and data from product literature does not generally identify the efficiency test method.
- It is not possible to determine performance trends based on construction or configuration (e.g., cast iron vs. plate steel, powered blowers vs. no blowers, etc.) trends in specific equipment type or construction based on published efficiencies. Further, EPA certification data shows no significant relationship between emissions and heating efficiency.
- Cordwood stoves require chimneys for venting combustion gases. Whether conventional masonry chimneys are used or metal chimney liners, these add considerable cost to the overall system. Accordingly, installed costs can be twice that of the wood stove itself.

Residential Wood Pellet Stoves

Return to Table of Contents

- In 2015, EPA published an update to its NSPS, limiting emissions for wood pellet stoves to 4.5 g/h. Prior to the 2015 EPA rule, most pellet stoves were exempt from EPA's NSPS requirements. The new rule did not institute efficiency standards but required that manufacturers test and certify the efficiency of their stoves. This standard took full effect on January 1, 2016.
- Prior to the 2015 rule, manufacturers could either submit efficiency data from laboratory testing or certify with the default efficiency value designated by EPA. EPA's default efficiency values were 63% for non-catalytic wood stoves and 72% for catalytic wood stoves. Under this system, few manufacturers submitted efficiency test data to EPA.
- Multiple test standards are commonly used to assess stove efficiency and data from product literature does not generally identify the efficiency test method.
- It is not possible to determine performance trends based on construction or configuration (e.g., cast iron vs. plate steel, powered blowers vs. no blowers, etc.) trends in specific equipment type or construction based on published efficiencies. Further, EPA certification data shows no significant relationship between emissions and heating efficiency.
- Wood pellet stoves may be able to be direct vented to the outdoors, eliminating the need for a chimney. This reduces the overall system cost as compared to a cord wood stove. However, they do use electricity to power the pellet feeder, the combustion air fan, and the blower. In the event of a power outage, a pellet stove can not operate without some back-up source of electricity (e.g., battery) .

Annual Maintenance Cost (2022$)[2]	20	20	20	20	20	20	20	20	20	20	20	20	20

1. Analysis is based on an average of medium and high draw pattern units, as this is most reflective of the market.
2. Maintenance includes manufacturer recommendation for the water heater to be drained and flushed annually to minimize deposition of sediment, maintain operating efficiency, and prolong product life. Available evidence indicates that this is performed in 10% of households.

Note:
Ranges represent the span of typical values.
Current standards went into effect April 16, 2015.
ENERGY STAR V. 4.0 went into effect January 5, 2022.
ENERGY STAR V. 5.0 will go into effect April 18, 2023
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (15.1, 1.76, 1).

U21806-MNSC-CE-0771-Att 4

Residential Gas-Fired Storage Water Heaters

Final

Return to Table of Contents

- The equations for Federal Standards and the voluntary ENERGY STAR requirements, if applicable, are:

Volume Range	Draw Pattern	Federal standard[1]	Federal minimum UEF for typical sizes	ENERGY STAR
≥ 20 gal and ≤ 55 gal	Very Small	UEF=0.3456-(0.002*Gal)	No models on the market	NA
	Low	UEF=0.5982-(0.0019*Gal)	0.54 for a 29-gallon water heater	NA
	Medium	UEF=0.6483-(0.0017*Gal)	0.58 for a 38-gallon water heater	0.64
	High	UEF=0.692-(0.0013*Gal)	0.64 for a 48-gallon water heater	0.68
> 55 gal and ≤ 100 gal	Very Small	UEF=0.647-(0.0006*Gal)	No models on the market	NA
	Low	UEF=0.7689-(0.0005*Gal)	No models on the market	NA
	Medium	UEF=0.7897-(0.0004*Gal)	No models on the market	0.78
	High	UEF=0.8072-(0.0003*Gal)	No models on the market	0.80

- There are currently no models on the market above 55 gallons (gal) due to the high UEF, which would require using condensing or gas-fired heat pump (e.g., absorption) technology to achieve.
- The cost of installation is typically $600 to $1200, which exceeds that of electric water heaters. This difference can be attributed to multiple differences; for example, gas-fired heaters require an extra 1.5 hours of labor for 2 plumbers.
- Condensing units are high efficiency and use PVC venting instead of stainless-steel. Condensing units also use an electrical supply for electronic ignition and power venting. Some building codes require condensate neutralizer filters.

Annual Maintenance Cost (2022$)[2]	210	210	210	210	210	210	210	210	210	210	210

1. Analysis is based on an average of medium and high draw pattern units, as this is most reflective of the market.
2. Oil-fired storage water heaters are typically cleaned and maintained under maintenance contracts. The annual cost of typical maintenance is based on maintenance contract prices from different oil-fired product suppliers as specified in the CWH EERE 2022 Preliminary Analysis.

Note:
Ranges represent span of typical values.
Current standards went into effect April 16, 2015.
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (16.2, 1.70, 1).

U21806-MNSC-CE-0771-Att 4

Residential Oil-Fired Water Heaters

Final

Return to Table of Contents

- The equations for Federal Standards and the voluntary ENERGY STAR requirements, if applicable, are:

Volume Range	Draw Pattern	Federal standard[1]	Federal minimum UEF for typical sizes	ENERGY STAR
≤ 50 gal	Very Small	UEF=0.2509-(0.0012*Gal)	No models on the market	NA
	Low	UEF=0.533-(0.0016*Gal)	No models on the market	NA
	Medium	UEF=0.6078-(0.0016*Gal)	No models on the market	NA
	High	UEF=0.6815-(0.0014*Gal)	0.64 for a 29-gallon water heater	NA

- There are no ENERGY STAR requirements for oil-fired storage water heaters.
- Annual shipments of residential oil-fired storage water heaters are approximately 4,000, which is less than 1% of shipments of residential gas-fired storage water heaters.
- Oil-fired storage water heaters often have smaller tanks with larger input ratings relative to natural gas-fired and electric storage water heaters.
- No condensing residential oil-fired storage water heaters currently exist in the U.S. market. Condensing oil-fired water heaters are generally not considered technologically feasible because the sulfur content in fuel oil leads to the condensate becoming corrosive.
- Residential oil-fired water heaters utilize power burners and have at least some level of electrical power consumption.
- The most efficient models on the market use a proprietary “turbo-flue” design to increase heat transfer to water.

Annual Maintenance Cost (2022$)[2]	20	20	20	20	20	20	20	20	20	20	20

1. Beginning in 2016, the efficiency metric for water heaters changed from energy factor (EF) to UEF based on DOE test procedures. The UEF values for the installed base in 2015 are converted values equivalent to 0.90 EF. Analysis is based on an average of low and medium draw pattern units, as this is most reflective of the market.
2. Similar to gas-fired and oil-fired storage water heaters, manufacturers recommend that electric storage water heaters be drained and flushed annually to minimize deposition of sediment, maintain operating efficiency, and prolong product life. The available evidence indicates that this practice is done in 10% of households.

Note:
Ranges represent span of typical values.
Current standards went into effect April 16, 2015.
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (15.7, 1.57, 1).

U21806-MNSC-CE-0771-Att 4

Residential Electric Resistance Storage Water Heaters

Final

Return to Table of Contents

- The equations for Federal Standards and the voluntary ENERGY STAR requirements, if applicable, are:

Volume Range	Draw Pattern	Federal standard[1]	Federal minimum UEF for typical sizes	ENERGY STAR
≥ 20 gal and ≤ 55 gal	Very Small	UEF=0.8808-(0.0008*Gal)	No models on the market	2.00
	Low	UEF=0.9254-(0.0003*Gal)	0.92 for a 27-gallon water heater	2.00
	Medium	UEF=0.9307-(0.0002*Gal)	0.92 for a 45-gallon water heater	2.00
	High	UEF=0.9349-(0.0001*Gal)	0.93 for a 50-gallon water heater	2.00
> 55 gal and ≤ 120 gal	Very Small	UEF=1.9236-(0.0011*Gal)	No models on the market	2.20
	Low	UEF=2.0440-(0.0011*Gal)	No models on the market	2.20
	Medium	UEF=2.1171-(0.0011*Gal)	2.05 for a 58-gallon water heater	2.20
	High	UEF=2.2418-(0.0011*Gal)	2.15 for a 80-gallon water heater	2.20

- The federal standards for residential electric storage water heaters apply to both electric resistance storage water heaters and heat pump water heaters.
  - The Federal standard levels for the ≤ 55-gallon range are achievable through electric resistance and heat pump technology.
  - The Federal standards for the > 55-gallon range and all ENERGY STAR levels are only achievable through heat pump technology.
- Typical storage volumes range from 25-55 gallons for electric resistance storage water heaters and 45-80 gallons for heat pump water heaters (HPWHs).

	2,940	3,000	2,230	2,230	2,450	2,120	2,330	2,010	2,210	1,910	2,100
Annual Maintenance Cost (2022$)[3]	20	20	20	20	20	20	20	20	20	20	20

1. Analysis is based on an average of low and medium draw pattern units, as this is most reflective of the market.
2. It is expected that costs for HPWHs will decrease over time as these products become more common. This analysis estimates these cost decreases for the higher range of costs.
3. For heat pump water heater design options, DOE assumed higher maintenance cost to take into account annual cleaning of the air filter, preventative maintenance cost to check the evaporator and refrigeration system, inspection of the condensate withdrawal system, and replacement of the condensate neutralizer filter, if applicable. However, this maintenance is estimated to occur in only 10% of households, so overall maintenance cost is similar to that of other electric resistance water heaters.

Note:
Ranges represent span of typical values.
ENERGY STAR V. 4.0 went into effect January 5, 2022.
Assume same lifetime as electric resistance water heaters.

U21806-MNSC-CE-0771-Att 4

Residential Heat Pump Water Heaters

Final

Return to Table of Contents

- Technology improvements have advanced efficiency and reliability, but the high first-cost and lack of awareness among consumers and contractors still precludes high-volume market penetration.
- New Federal standards that came into effect in April 2015 effectively mandate heat pump technology for electric storage water heaters with storage volume > 55 gallons.
- Integrated models are the most common configuration for residential HPWHs. Several major water heater manufacturers produce such models, and other competitors offer integrated or add-on units (for existing electric or indirect storage water heaters).
- Sales are estimated to be driven partly by rebates and tax credits at the utility, local, state, and Federal level.
- Resistive heating elements are virtually 100% efficient, but there is a jump in efficiency when heat pump technology is adopted because heat pumps' COP are usually between 2.5 and 4.
- Heat pumps raise the water temperature more slowly than resistive heating elements, so most models use backup resistive elements along with the heat pump when hot water demand is high. Most HPWHs allow the consumer to control whether resistive elements are used in periods of high demand (e.g., "hybrid mode" or "heat pump only mode").

Residential Solar Water Heaters

Final

Return to Table of Contents

DATA	2015	2020	2022		2030	2040	2050
	Installed Base	Installed Base	ENERGY STAR V. 4.0	Typical	Typical	Typical	Typical
Typical Capacity (ft^2)[1]	42	42	40	40	40	40	40
	65	65	54.4	54.4	54.4	54.4	54.4
Solar Uniform Energy Factor (SUEF)[2]	3.0	3.0	3.0	99.0	99.0	99.0	99.0
Average Life (y)	15	15	15	15	15	15	15
	30	30	30	30	30	30	30
Retail Equipment Cost (2022$)	7,710	7,710	6,430	6,430	6,430	6,430	6,430
Total Installed Cost (2022$)	10,650	10,650	8,060	8,060	8,060	8,060	8,060
Annual Maintenance Cost (2022$)[3]	80	80	80	80	80	80	80

1. Capacity selections are based on the range observed from medium draw units in the ENERGY STAR database. Medium draw represented the largest portion of units.
2. An SUEF of 3.0 is the required threshold for ENERGY STAR certification, yet a value of 99 was the most common observed SUEF among medium draw units. Note that an SUEF of 99 indicates that no backup heating was required for the applicable draw pattern, and all energy was provided by the solar collector. Since SUEF is a measure of hot water energy out divided by electrical or gas backup energy in, it will be infinite for cases where the collector provides all the hot water needed for the draw pattern – the Solar Rating and Certification Corporation's (SRCC's) OG-300 software is written to assign an SUEF of 99 to this case.
3. Annual maintenance is expected to be 0.5% to 1% of the total installation for 2022, 2030, 2040, and 2050.

Note:
Ranges represent span of typical values.
ENERGY STAR V. 4.0 went into effect January 5, 2022.

U21806-MNSC-CE-0771-Att 4

Residential Solar Water Heaters

Final

Return to Table of Contents

- Solar water heaters are not subject to federal energy conservation standards. The ENERGY STAR requirements are:

Applicable Products	Backup Fuel	ENERGY STAR Requirement	Test Method
Whole-home solar units	Gas	SUEF ≥ 3.0	ICC 900/SRCC 300-2020 Solar Thermal System Standard, Appendix A: Solar Uniform Energy Factor Procedure for Solar Water Heating Systems
	Electric	SEF ≥ 1.8	

- Solar water heaters can be either active or passive. An active system uses an electric pump to circulate the heat transfer fluid; a passive system has no pump. Most solar water heaters in the U.S. are the active type.
- Solar water heaters are also characterized as open loop (also called "direct") or closed loop (also called "indirect"). An open-loop system circulates household (potable) water through the collector. A closed-loop system uses a heat transfer fluid (water or diluted antifreeze, for example) to collect heat and a heat exchanger to transfer the heat to household water. Direct systems were observed as the most common product type and subject of this analysis.
- In 2020, stakeholders from the solar thermal industry developed the Solar Uniform Energy Factor (SUEF) Specification for solar water heaters to align with the UEF metric used by DOE for other water heating technologies.
- SUEF is also the metric used by the current ENERGY STAR Specification, and it replaced the Solar Energy Factor (SEF) metric.
- Over two-third of the current solar water heater market is in the southern or western U.S. (including Hawaii). A collector area of 42 square feet (ft^2) would be typical for these areas. Colder areas of the U.S. would require a larger collector (e.g., 65 ft^2).
- Installed costs are higher for colder areas where larger collectors are required. Costs also vary widely depending on collector quality, type of system, and site-specific characteristics.

Residential Gas-Fired Instantaneous Water Heaters

Final

Return to Table of Contents

- The equations for Federal Standards and the voluntary ENERGY STAR requirements, if applicable, are:

Volume Range	Draw Pattern	Federal standard[1]	Federal minimum UEF for typical sizes	ENERGY STAR
<2 gal and >50,000 Btu/h	Very Small	UEF=0.80	No models on the market	0.87
	Low	UEF=0.81	No models on the market	0.87
	Medium	UEF=0.81	0.81	0.87
	High	UEF=0.81	0.81	0.87

- The ENERGY STAR levels require the use of condensing technology.
- All of the major water heater manufacturers now offer an instantaneous water heater model.
- The maintenance costs include cleaning the water inlet filter and the heat exchanger of mineral deposits and replacing the water valve approximately once every five years for all instantaneous water heaters.
- When replacing a storage water heater with an instantaneous water heater, there are significant additional costs to upsize the gas supply line to ¾ inch from the typical ½ inch and change the venting.

[1]Energy Conservation Standards for Residential Water Heaters. 10 CFR 430.32(d).

Residential Electric Instantaneous Water Heaters

Return to Table of Contents

DATA	2015	2020	2022			2030		2040		2050	
	Installed Base	Installed Base	Current Standard	Typical	High	Typical	High	Typical	High	Typical	High
Representative Input Rate (kW)	3.5	3.5	3.5	3.5	3.5	3.5	3.5	3.5	3.5	3.5	3.5
Uniform Energy Factor (UEF)[1]	0.96	0.96	0.91	0.96	0.98	0.96	0.98	0.96	0.98	0.96	0.98
Average Life (y)	20	20	20	20	20	20	20	20	20	20	20
Retail Equipment Cost (2022$)	260	260	260	260	260	260	260	260	260	260	260
Total Installed Cost (2022$)	520	520	520	520	520	520	520	520	520	520	520
Annual Maintenance Cost (2022$)[2]	90	90	90	90	90	90	90	90	90	90	90

1. Analysis is based on an average of low, medium, and very small draw pattern units, as this is most reflective of the market.
2. Annual maintenance costs not provided in CWH EERE 2022 Preliminary Analysis. Maintenance costs determined from the following calculation: GIWH - (GSWH - ESWH) - i.e., the difference factor in maintenance between gas and electric storage heat pumps applied to gas instantaneous heat pumps.

Note:
Current standards went into effect April 16, 2015.
Assume same lifetime as gas-fired instantaneous water heaters.

U21806-MNSC-CE-0771-Att 4

Residential Electric Instantaneous Water Heaters

Final

Return to Table of Contents

- The Federal standards are:

Volume Range	Draw Pattern	Federal standard[1]	Federal minimum UEF for typical sizes
<2 gal	Very Small	UEF=0.91	0.91
	Low	UEF=0.91	0.91
	Medium	UEF=0.91	No models on the market
	High	UEF=0.92	No models on the market

- Electric instantaneous water heaters use electric resistance heating elements to heat water when there is a demand. Resistive heating elements are virtually 100% efficient, and the small storage capacities of these products means that they do not lose significant amounts of heat to the environment.
- The federal standards for these products require UEFs of 0.91 for very small, low, and medium draw pattern models and 0.92 for high draw pattern models.
- Most products currently on the market are in the very small draw pattern or the low draw pattern because electric resistance elements can only supply a limited quantity of heat on an instantaneous basis due to circuit amperage limitations.
- Many products are designed for point-of-use applications, such that the water heater only supplies water to one faucet or showerhead.

Residential Refrigerator-Freezers

Final

Return to Table of Contents

- Current Federal standards[1]:
  - Compliance required beginning September 15, 2014
  - Models divided into 32 product classes based on size (standard or compact), location of freezer (top, bottom, or side), type of defrost (automatic or manual), installation configuration (freestanding or built-in), and presence and configuration (through-the-door or inside cabinet) of automatic icemaker
  - Limits on annual electricity consumption expressed as functions of adjusted volume[2]
  - New product classes for built-in units
  - Amount by which standards are tightened varies by product class
- ENERGY STAR criteria limit annual electricity consumption to 10% less than the Federal standard
- Energy efficiency opportunities for refrigerators include:
  - More efficient compressor, including variable speed compressors
  - Brushless direct current (DC) fan motor (also known as ECM motor)
  - Variable defrost
  - Larger condenser
  - Dual evaporators
  - Vacuum-insulated panels
  - Refrigerants (Isobutane vs. R134a)

[1]Energy Conservation Standards for Residential Refrigerators, Refrigerator-Freezers, and Freezers. 10 CFR 430.32(a).
[2]Adjusted Volume (AV) = (Fresh Volume) + 1.76 × (Freezer Volume)

Residential Refrigerator-Freezers

Annual shipment volumes have rebounded from a sharp decline between 2006 and 2009, reaching approximately 11.4 million units in 2020.

Residential Freezers

Final

Return to Table of Contents

- Current Federal standards[1]:
  - Compliance required beginning September 15, 2014
  - Models divided into 10 product classes based on size (standard or compact), orientation (chest or upright), type of defrost (automatic or manual), installation configuration (freestanding or built-in), and presence of automatic icemaker
    - Current analysis focuses on the two representative product classes analyzed in the recent rulemaking, chest and upright freezers.
  - Limits on annual electricity consumption expressed as functions of adjusted volume[2]
    - Chest freezers and all other freezers except compact freezers (PC 9): 9.88AV + 143.7
    - Upright freezers with automatic defrost (PC 10): 12.43AV + 326.1
- ENERGY STAR criteria limit annual electricity consumption to 10% less than the Federal standard
  - No ENERGY STAR compliant products at the typical capacity for chest freezers
- Energy efficiency opportunities for freezers include:
  - Higher efficiency and/or variable-speed compressor systems
  - Larger heat exchangers
  - Permanent-magnet fan motor systems (vs. shaded pole motor (SPM) and PSC fan motors)
  - Demand defrost systems
  - Vacuum-insulated panels
  - Thicker insulation (though at a loss of consumer utility)
  - Refrigerants (Isobutane vs. R134a)
  - Variable anti-sweat heating
  - Use of forced convection condenser (for upright freezers)

[1]Energy Conservation Standards for Residential Refrigerators, Refrigerator-Freezers, and Freezers. 10 CFR 430.32(a).

Shipment volumes held steady between 2007 to 2016 at about 2 million units per year. Shipments jumped to 3 million units in 2020. Chest freezers represent about 60% of the market.

DATA	2015	2020	2022		2030		2040		2050	
	Installed Base	Installed Base	Typical	High	Typical	High	Typical	High	Typical	High
Typical Capacity (kBtu/h)	9	9	9	9	9	9	9	9	9	9
	23	23	23	23	23	23	23	23	23	23
Integrated Annual Energy Consumption (kBtu/y)[1]	1,061	914	914	730	914	730	914	730	914	730
Cooking Efficiency (%)	40	45	45	52	45	52	45	52	45	52
Average Life (y)	15	15	15	15	15	15	15	15	15	15
Retail Equipment Cost (2022$)[2]	290	310	310	330	310	330	310	330	310	330
Total Installed Cost (2022$)[2]	420	460	460	480	460	480	460	480	460	480
Annual Maintenance Cost (2022$)[3]	-	-	-	-	-	-	-	-	-	-

1. Although there is no performance standard in effect, the test procedure metric has changed from Cooking Efficiency (%) to Integrated Annual Energy Consumption (IAEC) (kBtu/h). The Consumer Cooking Products EERE 2020 notice of proposed determination (NOPD) used for 2020 and beyond in this analysis also determined IAEC using a different test procedure than the Consumer Cooking Products EERE 2016 SNOPR.
2. Equipment and installed costs are for cooktops only (not combined range units).
3. Annual maintenance costs are negligible.

Note:
The range for typical capacity represents the span of typical values.
Average life is determined using a Weibull distribution characterized by the following scale (α) and shape (β) parameters: (14.56, 5.73).

Retail Equipment Cost (2022$)[2]	740	770	770	810	770	810	770	810	770	810
Total Installed Cost (2022$)[2]	870	920	920	950	920	950	920	950	920	950
Annual Maintenance Cost (2022$)[3]	-	-	-	-	-	-	-	-	-	-

1. Although there is no performance standard in effect, the test procedure metric has changed from Cooking Efficiency (%) to IAEC (kBtu/y). The 2015 IAEC value is reflective of freestanding standard gas ovens, which was previously determined to be the most representative product class. IAEC for 2020 and beyond is reflective of freestanding self-clean gas ovens, which is the product class that makes up the majority of historical and projected gas oven shipments.
2. Equipment and installed costs are for ovens only (not combined ranges). Costs are reflective of freestanding self-clean oven units with single oven component, which represent the majority of the market.
3. Maintenance costs are negligible.

Note:
Ranges represent the span of typical values for a given parameter.
Average life is determined using a Weibull distribution characterized by the following scale (α) and shape (β) parameters: (14.56, 5.73).

Annual Maintenance Cost (2022$)[3]	-	-	-	-	-	-	-	-	-	-

1. IAEC of a natural gas range is calculated as the sum of the IAEC for a natural gas cooktop and natural gas oven. IAEC of the oven component is reflective of freestanding self-clean gas ovens, which represent the majority of the market. The 2015 IAEC value of the oven component is reflective of freestanding standard gas ovens, which was previously determined to be the most representative product class.
2. Retail and installed cost are reflective of a typical unit with standard 30-inch width and 4 to 5 cooking top heating elements. Based on data from DOE rulemakings, Gordian's RSMeans Data – Building Construction Costs 2023, and distributors, total installed cost is estimated to be around $150 more than retail equipment cost.
3. Maintenance costs are negligible.

Note:
Ranges represent the span of typical values for a given parameter.
Average life is determined using a Weibull distribution characterized by the following scale (α) and shape (β) parameters: (14.56, 5.73).

Residential Natural Gas Cooktops, Ovens, and Ranges

Return to Table of Contents

- DOE analyzes cooktops and ovens separately, although they are often sold together in a single unit that combines both a cooktop and an oven into a product referred to as a range.
- Since January 1, 1990, gas cooking products with an electrical supply cord have been required to not be equipped with a constant burning pilot light. This requirement extended to gas cooking products without an electrical supply cord, as of April 9, 2012.
- DOE published a final rule in 2009[1] in which it determined that no standard for cooking efficiency would be cost-justified.
- DOE initiated a standards rulemaking in 2014 to consider amended standards for cooking products, including gas cooktops and ovens[2].
- On September 2, 2016, DOE proposed performance-based standards for gas cooktops and ovens that would take effect in 2020, if adopted.
- DOE established the new IAEC metric, in kBtu/y, to replace cooking efficiency (%).
- On December 14, 2020, DOE initially determined that amended energy conservation standards for consumer conventional cooking products would not be economically justified and would not result in significant conservation of energy[3].
- On February 2, 2023, DOE proposed new and amended energy conservation standards for consumer conventional cooking products[4].
- The IAEC of a range is calculated as the sum of the IAECs for cooktops and ovens. However, retail and installation costs for a range are similar to the cost of an oven.

1. ENERGY STAR V. 1.1 applies to vented and ventless standard electric clothes dryers.
2. The efficiency metric changed from EF to combined energy factor (CEF) in 2015. The 2015 Installed Base CEF data accounts for units tested to appendix D1 and appendix D2, because data specific to each appendix is not available for that year.
3. Maintenance costs are negligible. DOE estimated that on average 2.7 percent of electric and 3.3 percent of gas residential clothes dryers are repaired each year. (EERE 2014)

Note:
DOE test procedures for consumer clothes dryers appear at title 10 of the Code of Federal Regulations part 430, subpart B, appendix D1 and appendix D2. The second test method, appendix D2, was finalized in a final rule published by DOE on August 14, 2013. For current standard testing, units must be tested according to either the appendix D1 or the appendix D2 test method. ENERGY STAR V. 1.1 requires certified units to be tested according to the appendix D2 test method. The appendix D1 and appendix D2 test methods determine CEF differently.
The current standard went into effect in January 2015.
ENERGY STAR V. 1.1 went into effect in May 2017.
The range for average life represents the span of typical values.

Residential Clothes Dryers

- Current standards[1] in effect since 2015:
  - For standard-size electric units : CEF ≥ 3.73 pound per kilowatt hours (lb/kWh)
  - For gas units: CEF ≥ 2.30 lb/kWh
  - Units may be tested according to the test method in appendix D1 or appendix D2, which was finalized in 2013.
- The main differences between appendix D1 and appendix D2 are:
  - Appendix D2 includes test methods that more accurately measure the effects of automatic cycle termination and that may result in differences in the total measured energy consumption of the test cycle as compared to the test methods in appendix D1.
  - Appendix D2 contains instructions for the testing of timer dryers, which include a lower final moisture content (FMC) of the test load as compared to the version of appendix D1 used for the 2011 rulemaking analysis.
- Efficiency improvement technologies for clothes dryers include:
  - Multi-step or modulating heat
  - Higher efficiency drum motors
  - Inlet air pre-heat
  - Better control systems for cycle termination
  - Heat pump (for electric clothes dryers)
- EPA developed ENERGY STAR V. 1.1, which became effective in 2017 and requires units to be tested according to the test method in appendix D2.
- Standard-size heat pump clothes dryers with CEF values up to 11.0 are currently available in the U.S. market. High initial cost has limited market penetration, but some utilities are offering rebates to support market penetration.

Shipment volumes have been on the rise since 2012. Gas dryers continue to account for about one-fifth of the market.

Residential Clothes Washers

Final

Return to Table of Contents

- The analysis treats front- and top-loading models separately due to their different energy use characteristics.
- Federal standards[1] for standard-capacity clothes washers (≥ 1.6 ft^3):

	Integrated Modified Energy Factor		Integrated Water Factor	
	Top-Loading	Front-Loading	Top-Loading	Front-Loading
Current DOE Standard (effective 1/1/2018)	≥ 1.57	≥ 1.84	≤ 6.5	≤ 4.7
Current ENERGY STAR V. 8.1 (effective 4/22/2021)	≥ 2.06	≥ 2.76	≤ 4.3	≤ 3.2

- In 2020, about 40% of top-loading models and almost all front-loading models achieved the ENERGY STAR level.
- Energy efficiency improvement technologies for clothes washers include:
  - Higher efficiency motors and higher spin speeds
  - Better load sensing for adaptive water fill control
  - Reduced water temperature and quantity, while providing equivalent cleaning and rinsing performance
- Maintenance costs include replacement or repair of the drain pump, control board, motor, rubber gaskets, or control panel knobs.
- The products on the market with the highest IMEF have significantly larger capacity and therefore use more energy per cycle than typical, smaller capacity products but still perform more efficiently on a per volume basis.

DATA	2015	2020	2022				2023	2030		2040		2050	
	Installed Base	Installed Base	Current Standard	Typical	ENERGY STAR V. 6.0	High	ENERGY STAR V. 7.0	Typical	High	Typical	High	Typical	High
Typical Annual Energy Use (kWh/y)	295	270	307	270	270	225	240	240	225	240	225	240	225
Water Consumption (gal/cycle)	4.25	3.50	5.00	3.50	3.50	2.40	3.20	3.20	2.40	3.20	2.40	3.20	2.40
Water Heating Energy Use (kWh/y)[1]	154	125	176	123	123	84	112	123	84	123	84	123	84
Average Life (y)	15	15	15	15	15	15	15	15	15	15	15	15	15
Retail Equipment Cost (2022$)	440	380	310	340	340	500	430	340	500	340	500	340	500
Total Installed Cost (2022$)	840	570	490	520	520	690	610	520	690	520	690	520	690
Annual Maintenance Cost (2022$)[2]	-	-	-	-	-	-	-	-	-	-	-	-	-

1. Refers to that portion of "Typical Annual Energy Use" that is the energy used to heat water in a separate water heater before it enters the dishwasher. The energy used to heat water inside the dishwasher cannot be disaggregated from the total.
2. Maintenance costs are negligible.

Note:
All values in table reflect 215 cycles/year according to the current test procedure at 10 CFR 430 Appendix C1.
The current standard went into effect in May 2013.
ENERGY STAR V. 6.0 went into effect in January 2016.
ENERGY STAR V. 7.0 will go into effect in July 2023.
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (15.9, 1.8, 1).

Residential Dishwashers

- Performance criteria for standard-capacity dishwashers (assumes 215 cycles/year):
  - Federal Standards:
    - May 30, 2013: ≤ 307 kWh/y, ≤ 5.0 gal/cycle (DOE Direct Final Rule, published May 2012)
  - ENERGY STAR Criteria:
    - Jan. 29, 2016: ≤ 270 kWh/y (5% allowance for connected), ≤ 3.5 gal/cycle (V. 6.0)
    - July 19, 2023: ≤ 240 kWh/y, ≤ 3.2 gal/cycle (V. 7.0, effective August 2023)
- ENERGY STAR has maintained a very high market share for several years (93% in 2021), so sales-weighted average efficiency has tracked ENERGY STAR levels.
  - Due to the historically high market penetration of ENERGY STAR products, it is expected that manufacturers will make the necessary adjustments so ENERGY STAR V. 7.0 levels will be typical in future projections.
- Test procedures:
  - Accounts for motor, dryer, booster heater (if present), and hot water from separate water heater, as well as standby and off-mode energy.
  - ENERGY STAR established a cleaning performance test method. While cleaning performance reporting is currently optional, V. 7.0 requires a cleaning index of 65 or higher for ENERGY STAR certification.
  - In January 2023, DOE established a test procedure at Appendix C2, which would go into effect at the time of any amended energy conservation standards. Appendix C2 establishes a minimum cleaning index threshold of 70 as a condition for a valid test cycle. The cleaning index threshold of 70 established by DOE is equivalent to the cleaning index threshold of 65 specified in ENERGY STAR V. 7.0.
- Efficiency improvement technologies for dishwashers include:
  - Better soil sensing
  - Control strategies
  - Water distribution (small pipes, fine filter, small sump, multiple spray arms, alternating water use) and controls (flow meter, temperature sensor)
  - Inline water heater (to minimize sump volume)
  - Separate drain pump, high-efficiency, variable-speed circulation pump motor
  - Condensation drying (rather than power dry)

1. In 2023, the new Energy Conservation Standards for Commercial Warm Air Furnaces (CWAF) took effect. These projections reflect the 2023 minimum thermal efficiency requirement for gas-fired furnaces, 81%.
2. When this analysis was previously conducted in EIA Technology Forecast Updates (2018), a typical input capacity of 400 kBtu/h was listed. An updated typical input capacity value of 250 kBtu/h was determined through an evaluation of the units in the DOE CCD as of August 2022. CWAF EERE 2015 also listed a representative input capacity of 250 kBtu/h.
3. DOE's efficiency metric for commercial furnaces accounts only for flue losses, not jacket losses.

Note:
The previous standard went into effect in January 1994. The current standard went into effect in January 2023.

U21806-MNSC-CE-0771-Att 4

Commercial Gas-Fired Furnaces

Final

Return to Table of Contents

- Until 2022, the Federal standard required minimum 80% thermal efficiency. This metric, more commonly called "combustion efficiency" in other contexts, accounts only for flue losses, not jacket losses.
  - The Federal standard applied to all units manufactured on or after January 1, 1994, with maximum rated heat input ≥ 225,000 Btu per hour.
  - On January 1, 2023, the minimum Federal standard increased to 81% thermal efficiency.
- ASHRAE Standard 90.1, which is used as a commercial building code in many states, stipulates that furnaces that are not within the conditioned space shall not have jacket losses exceeding 0.75% of the input rating.
- Commercial furnaces are typically non-condensing with thermal efficiencies ranging from 80% to 81%. Condensing commercial furnaces, which can achieve up to 95% thermal efficiency, were previously introduced to the market but are not currently available due to cost and reliability concerns. The highest thermal efficiency included in DOE's CCD at this time is 81%.
- Besides capacity, commercial units can differ from residential furnaces in terms of the control system (i.e., integration with a Building Management System, twinning, or other staging strategies). Commercial systems may also use a heat recovery system to pre-heat inlet air.

Commercial Electric Resistance Heaters

Final

Return to Table of Contents

- This analysis examined standard suspended electric wall and ceiling unit heaters, which are more common in commercial settings than baseboard electric heaters that were considered for the residential analysis.
- Electric unit heaters range in capacity from 2 to 80 kW (7 to 270 kBtu/h), with 5 to 50 kW (17 to 170 kBtu/h) being the most typical units on the market.
- Electric resistance heaters are considered near 100% efficient because there is no heat loss through ducts or combustion.
- Installation time and costs are estimated to be minimal.

Annual Maintenance Cost (2022$/kBtu/h)	-	-	-	-	-	-

1. Capacity is output.
2. Retail and installed costs for 2022 and forecasts for 2030 and beyond are based on Gordian's RSMeans Data – Building Construction Costs 2023. Maintenance costs are same as EIA Technology Forecast Updates (2018), updated to reflect 2022$. The costs shown are for one 165kW unit, which would equate to a steady load of approximately 550,000 Btu/h. Annual maintenance in a typical application would include draining the unit for removal of any accumulated scale or sludge buildup.

U21806-MNSC-CE-0771-Att 4

Final

Commercial Electric Boilers

Return to Table of Contents

- There are currently no federal standards associated with electric boilers.
- The costs shown are for one 165kW unit, which would equate to a steady load of approximately 550,000 Btu/h.
- Service life is determined mainly by water quality. Water conditioning (e.g., filters, softeners, de-alkalizers, chemical feeders) may be necessary for a given application.
- Annual maintenance in a typical application would include draining the unit for removal of any accumulated scale or sludge buildup.
- Minor end-use inefficiencies for electric boilers result from heat loss through the boiler (jacket losses).

Annual Maintenance Cost (2022$)[3]	1,710	2,100	2,100	2,100	2,140	2,100	2,100	2,140	2,100	2,140	2,100	2,140	2,100	2,140
Annual Maintenance Cost (2022$/kBtu/h)	3	3	3	3	3	3	3	3	3	3	3	3	3	3

1. The standard level shown here is for small (300 kBtu/h to 2500 kBtu/h) gas-fired hot water commercial packaged boilers, which are the most common type of boilers available on the market.
2. DOE's efficiency metric for most boiler types accounts for both flue and jacket losses; previously it did not. DOE continues to uses a combustion efficiency metric instead, for hot water boilers with heat input > 2,500,000 Btu/h.
3. Maintenance costs for 2018 and post-2018 are based on Commercial Packaged Boilers EERE 2020. The annualized maintenance costs estimated in the final rule differ for condensing vs. non-condensing boilers. Appendix 8E of the Commercial Packaged Boilers EERE 2020 TSD provides additional information on how the values are calculated.

Note:
The previous standard went into effect in March 2012.
The current standard went into effect in January 2023.
In December 2016, DOE issued a final rule titled Energy Conservation Program: Energy Conservation Standards for Commercial Packaged Boilers. This rule published in January 2020 with an effective date for January 2023.

U21806-MNSC-CE-0771-Att 4

Commercial Gas-Fired Boilers

Final

Return to Table of Contents

- Commercial packaged gas-fired boilers are classified by:
  - Heat input capacity
  - Produce steam or hot water
  - Draft type (natural draft or not) – for steam boilers
- The most common type of commercial gas-fired boilers are small gas-fired hot water boilers with 300,000-2,500,000 Btu/h rated heat input.
- Similar technologies to those used in the residential gas-fired boilers market can be leveraged in the commercial arena. The higher efficiency units typically include electronic ignition, power burners, and improved heat exchangers. Some gas-fired boilers also condense water vapor from the flue gases to improve heating efficiency.
- DOE published a final rule for commercial packaged boilers in January 2020 that updated the efficiency ratings of gas-fired commercial packaged boilers beginning January 2023.

1. Capacity is output.
2. ASHRAE 90.1 data are for units larger than 400 tons and for full-load optimized applications (Path A in ASHRAE 90.1-2019). Typical and high efficiency levels are determined based on the range of products currently available on the market.

Note:

For most chillers (including those in single-chiller applications and for peaking units in multi-chiller applications), the seasonal performance (represented by the integrated part-load value (IPLV)) is more indicative of annual expected performance than the full-load performance; performance of baseload chillers in multi-chiller applications, which typically operate at full-load, are well represented by the full-load efficiency value.

ASHRAE 90.1 went into effect in October 2019.

Ranges represent the span of typical values for a given parameter.

U21806-MNSC-CE-0771-Att 4

Commercial Centrifugal Chillers (Water-Cooled)

Final

Return to Table of Contents

- ASHRAE 90.1-2019 stipulates minimum efficiencies for centrifugal chillers separately from positive displacement water-cooled chillers. They are separated into 5 size categories, with categories divided at: 150, 300, 400, and 600 tons; ASHRAE 90.1-2019 also distinguishes between whether the unit will be optimized for full-load (Path A) or part-load operation (Path B). Data here are for Path A; a Path B chiller may have slightly high full-load consumption in exchange for much lower part-load consumption. For example, for a 600-ton unit:
  - Path A: ≥ 0.56 kW/ton full-load and ≥ 0.50 kW/ton IPLV
  - Path B: ≥ 0.585 kW/ton full-load and ≥ 38 kW/ton IPLV
- Federal Energy Management Program (FEMP) recommendations, last updated in 2020, match ASHRAE 90.1-2019.
- The highest efficiency centrifugal chillers incorporate some of the following:
  - Variable speed drive (VSD) compressors
  - Dedicated heat recovery (heat pump chiller)
  - Magnetic bearing technology (oil-free operation)
  - Greater heat exchanger surface areas; enhanced tube configurations (counterflow)
  - Optimized fluid flow velocities
  - High efficiency electric motors
  - Improved turbomachinery design, resulting in higher compressor efficiency
  - Better piping and valving, including electronic expansion valves
  - Evaporative condenser for the heat rejection equipment
- Installed costs vary widely depending on equipment needed for installation (e.g., crane) and size of system. This is a mature market with centrifugal chillers representing 75% of commercial chiller sales larger than 200 tons.
- Water-cooled chiller ratings do not include energy consumption of the cooling tower and therefore are not directly comparable to rating for air-cooled chillers. Water-cooled centrifugal chillers were selected for analysis due to a higher model share on the AHRI directory in comparison to air-cooled chillers.

U21806-MNSC-CE-0771-Att 4

Commercial Reciprocating Chillers (Air-Cooled Only)

Final

Return to Table of Contents

- Reciprocating chillers are most cost effective for small loads (30 to 150-ton range). However, reciprocating chiller market share continues to be supplanted by screw and scroll chillers. This trend has accelerated with the phase out of R-22, which was the refrigerant of choice for reciprocating products, which has in turn driven major manufacturers to replace their reciprocating product lines with scroll products (rather than redesign reciprocating products for new refrigerants). As a result, product options are very limited.
- Reciprocating chillers can be used in either air-cooled or water-cooled applications. Reciprocating chillers shown in the data are air-cooled. Air-cooled chillers are less efficient than the water-cooled models. Listed efficiencies include matched condensers and their associated energy use.
- ASHRAE 90.1-2019 stipulates minimum efficiencies for all air-cooled chillers together, including reciprocating chillers, while water-cooled chillers are separated by positive displacement (e.g., reciprocating) versus centrifugal models. Air-cooled chiller efficiencies are further split by size for more and less than 150 tons. ASHRAE 90.1-2019 also distinguishes between whether the unit will be optimized for full-load (Path A) or part-load operation (Path B). Data here are for Path A; a Path B chiller may have slightly lower full-load efficiency in exchange for much higher part-load efficiency. For example, for a 100-ton unit:
  - Path A: ≥ 10.1 EER full-load and ≥ 13.7 IPLV EER
  - Path B: ≥ 9.7 EER full-load and ≥ 15.8 IPLV EER
- FEMP (2022) recommendations for air-cooled chillers are:
  - Path A (<150 tons): ≥ 10.89 EER full-load and ≥ 13.7 IPLV EER
  - Path B (<150 tons): ≥ 9.7 EER full-load and ≥ 16.86 IPLV EER (same as 90.1-2019)
- The highest efficiency reciprocating chillers incorporate some of the following:
  - Multiple compressors for staged capacity control
  - Improved heat-exchangers

Commercial Screw Chillers (Air-Cooled Only)

Return to Table of Contents

- Screw chillers are common in 150 to 500-ton capacities but are most cost effective for small (<300 tons) loads; screw chillers dominate the current market for small to mid-size chillers.
- Screw chillers can be used in either air-cooled or water-cooled applications. Screw chillers shown in the data are air-cooled. Air-cooled chillers are less efficient than the water-cooled models. Listed efficiencies include matched condensers and their associated energy use.
- ASHRAE 90.1-2019 stipulates minimum efficiencies for all air-cooled chillers together, including screw chillers, while water-cooled chillers are separated by positive displacement (e.g., screw) versus centrifugal models. Air-cooled chiller efficiencies are further split by size for more and less than 150 tons. ASHRAE 90.1-2019 also distinguishes between whether the unit will be optimized for full-load (Path A) or part-load operation (Path B). Data here are for Path A; a Path B chiller may have slightly lower full-load efficiency in exchange for much higher part-load efficiency. For example, for a ≥ 150-ton unit:
  - Path A: ≥ 10.1 EER full-load and ≥ 14.0 IPLV EER
  - Path B: ≥ 9.7 EER full-load and ≥ 16.1 IPLV EER
- FEMP recommendations for air-cooled chillers (updated June 2020) are:
  - Path A (≥ 150 tons): ≥ 10.7 EER full-load and ≥ 14.0 IPLV EER
  - Path B (≥ 150 tons): ≥ 9.7 EER full-load and ≥ 16.4 IPLV EER
- The highest efficiency screw chillers incorporate some of the following:
  - Variable speed compressors and/or multiple compressors
  - Economizers
  - Improved heat-exchangers

Commercial Scroll Chillers (Air-Cooled Only)

Return to Table of Contents

- Scroll chillers range in size from ~20 tons to ~200 tons and can be used in either air-cooled or water-cooled applications. They are the most common type of chiller for small chiller plants. The scroll chillers shown in the data are air-cooled, which is most common. Air-cooled chillers are less efficient than the water-cooled models. Listed efficiencies include matched condensers and their associated energy use.
- ASHRAE 90.1-2019 stipulates minimum efficiencies for all air-cooled chillers together, including scroll chillers, while water-cooled chillers are separated by positive displacement (e.g., scroll) versus centrifugal models. Air-cooled chiller efficiencies are distinct for more and less than 150 tons. ASHRAE 90.1-2019 also distinguishes between whether the unit will be optimized for full-load (Path A) or part-load operation (Path B). Data here are for Path A; a Path B chiller may have slightly lower full-load efficiency in exchange for much higher part-load efficiency. For example, for a 100-ton unit:
  - Path A: ≥ 10.1 EER full-load and ≥ 13.7 IPLV EER
  - Path B: ≥ 9.7 EER full-load and ≥ 15.8 IPLV EER
- FEMP recommendations for air-cooled chillers (updated June 2020) are:
  - Path A (< 150 tons): ≥ 10.7 EER full-load and ≥ 13.7 IPLV EER
  - Path B (< 150 tons): ≥ 9.7 EER full-load and ≥ 15.9 IPLV EER
- The highest efficiency scroll chillers incorporate some of the following:
  - Multiple compressors for staged capacity control
  - Improved heat-exchangers
  - Variable speed compressor (or other modulation controls)
- With the phase out of R-22, manufacturers have replaced many of their small reciprocating chiller products with equivalent scroll products, making them a primary choice for small tonnage applications.

1. Capacity is output.

Note:
This analysis assumes a water-cooled chiller; both gas-fired chiller types (absorption and engine-driven) are shown. COP values for double-effect absorption chillers are shown.
For most chillers (including those in single-chiller applications and for peaking units in multi-chiller applications), the seasonal performance (represented by the IPLV) is more indicative of annual expected performance than the full-load performance; performance of baseload chillers in multi-chiller applications, which typically operate at full-load, are well represented by the full-load efficiency value.
ASHRAE 90.1 went into effect in October 2019.
CA Title 24 went into effect in January 2020.
Ranges represent the span of typical values for a given parameter.

Commercial Gas-Fired Chillers (Water-Cooled, Direct-Fired Only)

Return to Table of Contents

- Gas-fired chillers are available as either air-cooled (~25-50 tons) or water-cooled (150+ tons). This analysis covers only water-cooled chillers of two varieties: absorption and engine-driven vapor compression (direct-fired only; indirect steam or hot water driven units are excluded).
- Direct gas firing provides high enough temperatures to operate double effect absorption chillers, which operate at a 50-60% higher COP than single effect systems. Triple effect chillers, though not commercially available, can boost cooling COP 30-50% beyond double effect chillers. Some companies have worked on prototype direct-fired triple effect absorption chillers, but prohibitively high cost of advanced high heat/corrosion-resistant materials required for triple effect absorption chillers suggests that this technology will not likely have an impact on the market in the near-term.
- Gas-fired engine-driven chillers pair conventional vapor compression systems (typically screw or centrifugal compressors) with natural gas powered-reciprocating engines. They exhibit higher peak cooling COP than absorbers, and engine modulation results in better part-load performance. Future efficiency improvements for engine-driven chillers are not anticipated. Engine-driven chillers allow the opportunity to recover waste heat for useful purposes.
- Maintenance costs for engine-driven chillers are higher than for other chillers because they include all the typical components of a vapor compression chiller in addition to an engine; the engine maintenance costs vary depending on the annual run hours of the unit.
- Limited sales data suggest that the U.S. market for gas-fired chillers is very limited and is mostly for replacement units, not for new installations. Recent increases in electric chiller efficiency have narrowed the operating cost differential with gas chillers. Asia has the majority of the global gas-fired chiller market.
- Gas-fired chiller installations are particularly valuable in locations where electric rates are high and gas prices are low (i.e., low spark spread), where digester or landfill gas sources are available, or where waste heat sources are available (e.g., an industrial process or microturbine CHP system) that could be used with a hybrid direct/indirect-fired absorption chiller to offset the use of natural gas.

Annual Maintenance Cost (2022$/kBtu/h)	4	4	4	4	4	4	4	4	4	4	4	4	4	4	4	4

1. Values shown are for air-cooled small commercial packaged air conditioners with either electric resistance heating or no heating within the same enclosure. DOE published a direct final rule for commercial packaged air conditioners and heat pumps in January 2016 with initial standards becoming effective in 2018 and additional standards becoming effective in 2023. As part of this rulemaking, DOE changed the regulated metric from EER to integrated energy efficiency ratio (IEER).
2. DOE investigated the relationship between IEER and EER. Because the relationship between IEER and EER is weak, this analysis estimates EER values based on the average of the values seen at a given IEER.
3. Examples of annual maintenance services include, check tensions, condition, and alignment of belts and adjust as necessary; lubricate shaft and motor bearings; replace air filters; clean coils, drain pan and piping, blowers, fan motors as required; check refrigerant pressure and compressor oil level; etc.
4. The 2022 typical efficiency is based on the average IEER from DOE's CCD. The 2022 high efficiency is based on the most-efficient model in DOE's CCD, but costs are estimated based on the most efficient unit analyzed in CUAC EERE 2016, which had an IEER of 21.5.

Note:
EER is the ratio of the cooling capacity (in Btu/h) to the power input (in watts) and provides a measure of the efficiency of equipment operating at full load (i.e., 100 percent cooling capacity) in high-ambient-temperature conditions (i.e., 95 °F). IEER is a single number part-load efficiency based on weighting of EER at various load capacities. Efficiency Conversion is the conversion of IEER from a [(Btu/h)/W] metric to a metric in the same units.
The previous standard went into effect in January 2018. The current standard went into effect in January 2023.
ENERGY STAR V. 3.1 went into effect in January 2018. ENERGY STAR V. 4.0 went into effect in January 2023.

Commercial Gas-Fired Engine-Drive Rooftop Air Conditioners

Final

Return to Table of Contents

- There are only a few gas-fired engine-driven rooftop units currently available in the U.S. market. The first unit was introduced in 2010. It is an 11-ton packaged heat pump with dual scroll compressors, variable refrigerant flow, and a variable speed supply fan. Engine coolant heat recovery improves the heating mode COP.
- There are currently no Federal requirements on gas-fired engine-driven rooftop air conditioners or heat pumps.
- Annual sales of the engine-driven rooftop heat pump are estimated at less than 5,000 units per year.

1. COP values listed are assessed at a "ground loop" test condition, which is representative of closed loop GSHP operating conditions. However, DOE sets standards at a "water loop" test condition. The AHRI directory lists COP ratings at both sets of test conditions and is used to convert between them where necessary.
2. EER values listed are assessed at a full-load "ground loop" test condition, which is representative of closed loop GSHP operating conditions. However, DOE sets standards at a full-load "water loop" test condition. The AHRI directory lists EER ratings at all sets of test conditions and is used to convert between them where necessary.

Note:
Residential and commercial GSHPs are very similar - the main difference in data presented is the different capacity (3-ton vs. 4-ton) and slightly higher installation costs for commercial GSHP. DOE does not distinguish between residential and commercial units in its regulations.

U21806-MNSC-CE-0771-Att 4

Commercial Ground-Source Heat Pumps

Final

Return to Table of Contents

- The most common commercial ground-source heat pump systems are closed-loop in which water or anti-freeze solution is circulated through plastic pipes buried underground. Commercial water-to-air heat pumps (WAHPs) range in size from 1 ton or less to over 500 tons depending on whether a distributed or centralized architecture is used. Distributed systems are more prevalent.
- Most geothermal WAHPs are rated for capacity and efficiency based on the ISO 13256-1 standard. Heating and cooling efficiency measurements under this standard include input energy for fans and pumps on a proportional basis that only includes that power required to transport air and liquid through the heat pump. The reason for this method is to simplify comparisons between heat pumps and to allow equipment to be optimized for real world conditions without suffering rating penalties. Real world energy use will exceed ratings predictions as a result of higher fluid static pressure requirements.
- ISO 13256-1 cooling rating conditions require 77 °F entering water temperature and 80.6 °F entering air temperature. More typical peak design criteria would be 80-90 °F entering water temperature and 75 °F entering air temperature. As a result, ISO 13256-1 rated cooling efficiency would be higher than typical design peak operation.
- Some WAHPs include efficiency data for a part-load operating condition as allowed by ISO 13256-1 for multiple stage or variable speed compressors. No seasonal energy efficiency metric (analogous to SEER or IEER) currently applies to WAHPs. The annual performance of a geothermal WAHP system can vary more widely than for other system types due to the large influence of ground loop design and characteristics.
- The ENERGY STAR criteria for ground-source heat pumps apply only to residential applications.
- Installation cost is for a closed loop system and includes necessary accessories. The ground loop heat exchanger and distribution pumping systems represent a majority of the installation cost.
- Low end WAHPs utilize single stage compressors. Higher efficiency units incorporate multiple stage or variable speed compressor controls to improve efficiency as well as humidity and temperature control. Variable speed ECM fan motors also improve overall energy efficiency.

1. Typical capacity is representative of units with the most shipments. It was also the representative cooling capacity for DOE's analysis in PTAC & PTHP EERE 2022 NOPD.
2. Typical values for 2022 and beyond are based on the efficiency level that has the largest market share per PTAC & PTHP EERE 2022 NOPD.
3. High values for 2022 and beyond are based on the max-tech level from PTAC & PTHP EERE 2022 NOPD.

Note:
The current standard went into effect in October 2012.

1. Different levels of standby loss were not included in this analysis.
2. Maintenance consists of sediment and scale removal once or twice per year and replacement of miscellaneous components such as gaskets and sealants. Condensing units have an additional cost for replacement of condensate neutralizer media every two years.

Note:
The current standard went into effect in October 2015.
ENERGY STAR V. 2.0 went into effect in October 2018.
The range of retail and installed costs represent the range from replacement market to new construction market.

U21806-MNSC-CE-0771-Att 4

Commercial Gas-Fired Storage Water Heaters

Final

Return to Table of Contents

- Input capacity > 155 kBtu/h and storage capacity ≤ 140 gal
- Federal standard:
  - Minimum thermal efficiency: 80%
  - Maximum standby loss (Btu/h) : Input Rate/800 + 110 × (Rated Volume)$^{1/2}$
- ENERGY STAR requirements:
  - Minimum thermal efficiency: 94%
  - Maximum standby loss (Btu/h): 0.84 × [(Input Rate/800) + 110 × (Rated Volume)$^{1/2}$]
- Baseline units are typically constructed similarly to residential units, though with higher input capacities (and often higher storage volumes).
- High-efficiency units include condensing heat exchangers (typically stainless or enameled steel) to extract additional heat by condensing water vapor in flue gases. Condensing units also include an inducer fan system or power burner. The heat exchanger is typically contained within the tank, but some designs consist of an external heating module attached to a storage tank. Condensing units are expected to be the majority market share by 2030.
- Maintenance consists of sediment and scale removal once or twice per year and replacement of miscellaneous components such as gaskets and sealants. Condensing units have an additional cost for replacement of condensate neutralizer media every two years.

Final

Commercial Electric Resistance Storage Water Heaters

Return to Table of Contents

- Federal standard:
  - Maximum standby loss (%/h) : 0.30 + 27/Measured Storage Volume
  - Minimum thermal efficiency: no standard, but all units have an efficiency ≥ 98%
- Storage capacity: typically, 50 to 120 gallons, though smaller and larger units exist for specialized applications
- Commercial units are typically constructed similar to residential units, though with higher input capacities (and often higher storage volumes).
- There is very little variation in thermal efficiency on the market; variation in standby loss is typically due to tank design and insulation thickness.
- Maintenance consists of sediment and scale removal once or twice per year.

U21806-MNSC-CE-0771-Att 4

Commercial Electric Resistance Storage Water Heaters

Final

Return to Table of Contents

Annual shipments increased by almost 50% between 2002 and 2008. After a small dip in shipments in 2009, annual shipments have increased by about 173% between 2009 and 2017, stabilizing between 140-150 thousand shipments per year since then.

Annual Maintenance Cost (2022$/kBtu/h)	1	1	1	1	1	1	1

1. Water flow rate scales with typical capacity. The storage tanks must be purchased and installed separately from the HP unit. The typical output and flow rate provided are near the median of the products available on the market currently.
2. Costs are same as EIA Technology Forecast Updates (2018), updated to 2022$. Updated representative costs for commercial heat pump water heaters are not available due to the extremely small market for these products.

Note:
ENERGY STAR V. 2.0 went into effect in October 2018.

U21806-MNSC-CE-0771-Att 4

Commercial Heat Pump Water Heaters

Final

Return to Table of Contents

- Typical commercial HPWHs (CHPWHs) are add-on units designed to be used with a storage tank(s); integrated CHPWHs have emerged on the market (i.e., heat pump module and storage tank combined in one unit) in recent years.
- CHPWHs serve only a small portion of the commercial water heating (CWH) market, with the ENERGY STAR database listing only two manufacturers, each with one basic model listed.
- CHPWHs can extract heat from either air or water for heating potable water ("air-source" or "water-source"). The capacity of air-source CHPWHs falls at lower ambient air temperatures.
- Air-source CHPWHs cool the surrounding air, which can be desirable when installed indoors in applications with a year-round cooling load (e.g., a commercial kitchen).
- Output capacities for CHPWHs range from 17 kW to over 70 kW for air-source units and over 600 kW for water-source units.
- Some commercial applications require water as hot as 180 °F, such as dishwashing; however, most CHPWHs cannot deliver hot water at temperatures higher than 150 °F.
- There are no current Federal standards for CHPWHs, but DOE prescribes a test procedure for determining COP_h for CHPWHs.
- The most recent ENERGY STAR V. 2.0 specification for CWH equipment went into effect in October 2018. It specifies a COP_h level of 3.0 for CHPWHs.

1. Different levels of standby loss were not included in this analysis.

Note:
The commercial oil-fired water heaters market is very small; currently, there are only 4 basic models in DOE's CCD. DOE's rulemaking analysis for oil-fired water heaters has not been updated since 2001. The retail, installed, and maintenance costs have been updated from EIA Technology Forecast Updates (2018) to 2022$.
The current standard went into effect in October 2015.

U21806-MNSC-CE-0771-Att 4

Commercial Oil-Fired Storage Water Heaters

Final

Return to Table of Contents

- Input capacity > 155 kBtu/h and storage capacity ≤ 140 gal
- Federal standard:
  - Minimum thermal efficiency: 80%
  - Maximum standby loss (Btu/h) : Input Rate/800 + 110 × (Rated Volume)$^{1/2}$
- Condensing units do not exist, thus the highest thermal efficiency on the market is 82%.
- Commercial units are typically constructed similar to residential units, though with higher input capacities (and often higher storage volumes).
- Maintenance costs include sediment and scale removal once or twice per year.
- The market for commercial oil-fired storage water heaters is very small; shipments are approximately 3% of shipments for commercial gas-fired storage water heaters.

1. While EIA Technology Forecast Updates (2018) included high values reflecting condensing models, models currently available in the market do not exceed 80% efficiency.
2. The 2012 and 2018 installed base costs are the same as EIA Technology Forecast Updates (2018), updated to 2022$. Retail costs for 2022 and later are based on the range of costs for products on the market today. Installed costs assume a $300 installation price.

U21806-MNSC-CE-0771-Att 4

Commercial Booster Water Heaters

Final

Return to Table of Contents

- Booster water heaters are installed, often at the point of use, in series with the main service water heating system to boost service water temperatures. The main service water heating system may provide 110-140 °F water, and the booster water heater may increase that temperature to 180-195 °F. Typical commercial applications for booster water heaters include commercial dishwashers, laundromats, hospitals, and car washes.
- Commercial booster water heaters are regulated by DOE as either storage or instantaneous water heaters, depending on the ratio of input capacity to storage volume. Units with input capacity < 4,000 Btu/h per gallon of stored water are storage water heaters; all other units are instantaneous water heaters.
- DOE's regulations do not currently include standards for electric instantaneous water heaters, but standards are included for electric storage water heaters, gas-fired instantaneous water heaters, and gas-fired storage water heaters.
- Condensing gas-fired booster water heaters, those with an efficiency of 90% of more, were analyzed previously. There are no condensing units currently on the market. Condensing gas-fired booster water heaters can only operate if the incoming water temperature is below 130 °F so there is enough heat transfer to condense.
- Booster water heaters typically have short lifetimes because of high usage and extreme temperatures.
- Shipments are small due to the limited number of applications.

1. Commercial gas-fired instantaneous water heaters are categorized into two groups: tankless water heater and hot water supply boiler. Tankless units are similar in design to residential tankless units. The hot water supply boiler has a much higher input and is similar in design to boilers. The large variation of total input capacity and design causes a large range of costs. The range of retail, installed, and maintenance costs represent the differences in design, as well as the cost ranges arising from replacement versus new construction markets.
2. High efficiency was determined based on DOE's CCD. The most efficient tankless water heater has a thermal efficiency of 96%. The most efficient hot water supply boiler has a thermal efficiency of 99%.
3. Maintenance consists replacement of miscellaneous components such as gaskets and sealants. Condensing units have an additional cost for replacement of condensate neutralizer media every two years.

Note:
For the installed base, current standard, and typical costs, low values represent costs for tankless water heaters in the replacement market while high values represent costs for hot water supply boilers in the new construction market. The range of costs for the High values are estimated costs for hot water supply boilers in the replacement and new construction market.
ENERGY STAR V. 2.0 went into effect in October 2018.

U21806-MNSC-CE-0771-Att 4

Commercial Gas-Fired Instantaneous Water Heaters

Final

Return to Table of Contents

- Storage Capacity < 10 gallons and ≥ 10 gallons
- Federal standard:
  - Minimum thermal efficiency: 80%
  - Maximum standby loss (Btu/h): Input Rate/800 + 110 x (Rated Volume)$^{1/2}$
- ENERGY STAR requirements:
  - Minimum thermal efficiency: 94%
- Wall-mounted ("tankless") units typically do not exceed ~400,000 Btu/h and are similar in design to residential tankless units. Floor-mounted units ("circulating" or "volume" water heaters) are similar in design to boilers and can have input capacities in the millions of Btu/h. Floor-mounted units are typically installed with a storage tank.
- Despite high available input capacities, some installations use multiple units staged together, which may have reliability and/or efficiency benefits.
- Similar to storage water heaters, higher efficiencies are achieved with condensing operation, which requires a condensing heat exchanger and inducer fan or power burner. Some units include both non-condensing and condensing heat exchangers, while others include a single condensing heat exchanger.
- When replacing a storage water heater with an instantaneous water heater, there may be significant additional costs to upsize the gas supply line and change the venting.

U21806-MNSC-CE-0771-Att 4

Commercial Gas-Fired Instantaneous Water Heaters

Final

Return to Table of Contents

Annual shipments for gas-fired instantaneous tankless water heaters have gradually increased since 2000 while those for gas-fired instantaneous hot water supply boiler water heaters peaked in 2008 and have been decreasing since then, recently stabilizing around 10,000 annual shipments.

1. Typical capacity refers to the solar collector panel area. It was determined using the SRCC database as the average value of the largest bin (in terms of capacity) with the greatest number of units.
2. In 2020, the efficiency metric for solar water heaters changed from SEF to SUEF. There is no equation or scaling factor readily available to translate SEF to SUEF. Accordingly, for the 2012 and 2018 installed base, SUEF was determined using the 2020 ENERGY STAR data set assuming the typical SEF/SUEF value was similar between 2012-2020. For 2022 and beyond, due to lack of SUEF data, it is assumed that a typical electric backup unit would meet the ENERGY STAR criteria. ENERGY STAR specifies a minimum SUEF of 3.0 for electric backup units and 1.8 for gas backup units.
3. Costs are for an indirect (active closed loop) system, including tank and backup heater. Smaller capacity/cost systems are typical for southern & western states (>two-third of the current market). Higher capacity/cost systems are required in colder/cloudier regions. The 2012 and 2018 installed base costs are updated from EIA Technology Forecast Updates (2018) to 2022$.
4. Annual maintenance is expected to be 0.5% to 1% of the total installation.

Note:
ENERGY STAR V. 4.0 went into effect in January 2022. ENERGY STAR V. 5.0 will go into effect in April 2023 but the ENERGY STAR criteria for solar water heaters will remain the same in ENERGY STAR V. 5.0.

U21806-MNSC-CE-0771-Att 4

Commercial Solar Water Heaters

Final

Return to Table of Contents

- In 2020, a diverse group of stakeholders from the solar thermal industry developed the SUEF Specification for solar water heaters. The goal of this specification is to align with the UEF metric used by DOE for other water heating technologies.
- SUEF is also the metric used by the current ENERGY STAR Specification, and it replaced the SEF metric.
- EIA Technology Forecast Updates (2018) presented results using SEF and solar fraction (SF). SEF is currently not used in either the ENERGY STAR or SRCC databases; accordingly, this report presents results according to SUEF. SF is the portion of the total conventional hot water heating load (delivered energy and tank standby losses). SF varies from 0 to 1.0. Typical solar fraction values are 0.5–0.75.
- There is no equation or scaling factor readily available to translate SEF to SUEF. Accordingly, for the 2012 and 2018 installed base, SUEF was determined using the 2020 ENERGY STAR data set assuming the typical SEF/SUEF value was similar between 2012-2020. For 2022 and beyond, SUEF is the average SUEF for solar water heaters with a "high-usage" draw pattern from the current ENERGY STAR qualified product list.
- Commercial solar water heaters are typically custom designed for a specific installation.
- Commercial solar water heaters may include backup heating, from sources such as electric resistance or hydronic heat (supplied from a gas-fired boiler or geothermal heat pump).
- Storage volumes of tanks for commercial solar water heaters can span from 140 gallons to over 2,000 gallons.
- SRCC's OG-300 can be used to certify commercial systems, but most commercial systems are larger and unique; this certification program is mostly used for residential solar water heaters.
  - Many incentive programs require that solar collectors for commercial systems be certified to SRCC's certification program for collectors, OG-100.

1. ENERGY STAR does not cover combination products that include griddles, ranges, and ovens in one single package. The ENERGY STAR levels provided here reflect specifications for individual products. Range tops are not covered by ENERGY STAR.
2. ENERGY STAR V. 3.0 updated the requirements for commercial ovens from V. 2.2, effective January 2023. Data shown is reflective of a standard full-size convection oven that holds 5 or more pans.
3. Combined energy efficiency and combined idle energy rate are calculated as a weighted average of each component using typical daily operating hours sourced from Food Service Technology Center (FSTC). Typical daily operating hours are assumed to be 12 hours for the griddle component, 8 hours for the oven component, and 12 hours for the range component.
4. Products in the commercial cooking market generally do not scale in price with relation to cooking efficiency. Distributors also do not provide this information.
5. Maintenance costs are negligible.

Note:
ENERGY STAR V. 2.2 went into effect in October 2015. ENERGY STAR V. 3.0 went into effect in January 2023.

Commercial Ranges with Griddle and Oven

Final

Return to Table of Contents

- Combined product that typically includes 2-6 range tops, a 24 in. x 24 in. griddle surface, and one or two half- or full-size ovens.
- Combined product is not covered by ENERGY STAR. However, the individual product ENERGY STAR V. 2.2 specifications are provided below.

Product	ENERGY STAR V. 2.2 Requirements	Gas	Electric
Griddle	Cooking Energy Efficiency	≥ 38%	≥ 70%
	Normalized Idle Energy Rate	≤ 2,650 Btu/h per ft^2	≤ 0.320 kW per ft^2
Oven	Cooking Energy Efficiency	≥ 46%	≥ 71%
	Idle Energy Rate	≤ 12,000 Btu/h	Half size: ≤1.00 kW Full size: ≤1.60 kW

- ENERGY STAR does not provide certification for range tops.
- There are no Federal standards for commercial cooking products.
- Product pricing in this market do not scale with efficiency, but rather depend on a number of other factors such as brand name, aesthetics, and additional features.

1. Interior volume is characterized by the product size classes reported by ENERGY STAR. The small size class covers units with interior volume less than 13 ft^3. Interior volume for the small size class was determined based on the units in the ENERGY STAR database, accessed February 2023.
2. Maximum idle energy rate is a function of interior volume. For the small size class, ENERGY STAR and high values were determined for a representative 7.8 ft^3 using the ENERGY STAR database, accessed February 2023. The typical value was assumed to be equivalent to the state standard for a representative 7.8 ft^3 unit.
3. Annual energy use is determined using the latest FEMP data from December 2021, which assumes that a typical 22.4 ft^3 commercial hot food holding cabinet uses an average of 9 hours per day and 365 days per year. The small size class is assumed to use the same number of annual usage hours as the medium size class.
4. Retail equipment costs were determined using distributor information for undercounter, half-size, and full-size hot food holding cabinets.
5. Additional installation costs and maintenance costs are negligible.

Note:

ENERGY STAR V. 2.0 went into effect in October 2011 and was revised in December 2022. Massachusetts, Nevada, and Rhode Island state standards have adopted the ENERGY STAR V. 2.0 criteria that went into effect in October 2011. The majority of state standards (California, Colorado, Connecticut, DC, Maryland, New Hampshire, Oregon, Rhode Island, Vermont, and Washington) implement the ENERGY STAR V. 1.0 specification that went into effect in August 2003, which is recorded in the table. ENERGY STAR V. 1.0 specifies a maximum idle energy rate of 40 W per cubic foot of interior volume.

1. Interior volume is characterized by the product size classes reported by ENERGY STAR. The large size class covers units with interior volume greater than or equal to 28 ft^3. Interior volume for the large size class was determined based on the units in the ENERGY STAR database, accessed February 1, 2023.
2. Maximum idle energy rate is a function of interior volume. For the large size class, ENERGY STAR and high values were determined using the ENERGY STAR database, and the typical value uses the assumption that ENERGY STAR units are reported to be 70% more efficient than typical units.
3. Annual energy use is determined using the latest FEMP data from December 2021, which assumes that a typical 22.4 ft^3 commercial hot food holding cabinet uses an average of 9 hours per day and 365 days per year. The large size class is assumed to use the same number of annual usage hours as the medium size class.
4. Retail equipment costs were determined using distributor information for undercounter, half-size, and full-size hot food holding cabinets.
5. Additional installation costs and maintenance costs are negligible.

Note:
ENERGY STAR V. 2.0 went into effect in October 2011 and was revised in December 2022. Massachusetts, Nevada, and Rhode Island state standards have adopted the ENERGY STAR V. 2.0 criteria that went into effect in October 2011. The majority of state standards (California, Colorado, Connecticut, DC, Maryland, New Hampshire, Oregon, Rhode Island, Vermont, and Washington) implement the ENERGY STAR V. 1.0 specification that went into effect in August 2003, which is recorded in the table. ENERGY STAR V. 1.0 specifies a maximum idle energy rate of 40 W per cubic foot of interior volume.

U21806-MNSC-CE-0771-Att 4

Commercial Hot Food Holding Cabinets

Final

Return to Table of Contents

- Hot food holding cabinets are used in commercial kitchens to keep food warm until it is served.
- While available in many shapes and sizes, interior volumes around 21.4 ft^3 were reported as typical in many settings in EIA Technology Forecast Updates (2018). FEMP currently lists 22.4 ft^3 as a representative unit size.
- Annual unit energy consumption can range from < 1,000 to > 30,000 kWh/y, depending on size, efficiency, and usage.
- Energy performance metric is "Idle Energy Consumption Rate" in Watts, measured using ASTM Standard F2140-11.
- There are no Federal standards for hot food holding cabinets, but seven States have identical standards.
  - The first State standard took effect in California in 2006; this standard is now considered the typical or "baseline" product. It is also equivalent to the ENERGY STAR V. 1.0 Specification that went into effect in August 2003.
  - ENERGY STAR V. 2.0 went into effect in October 2011.
- Maximum Idle Energy Consumption Rate for products $12 \leq V < 28$:
  - State standards: $\leq 40 \times V$ (baseline)
  - ENERGY STAR V. 2.0: $\leq 2.0 \times V + 254$ (about 65% below baseline)

  where V is interior volume in ft^3.
- The most efficient products are about 80% below baseline.
- Energy savings achieved with insulation, automatic door closers, magnetic door gaskets, and Dutch doors (half-doors).

Objective

The objective of this study is to develop baseline and projected performance/cost characteristics for residential and commercial end-use equipment.

- Installed base in 2012 and 2018 (for commercial products) or 2015 and 2020 (for residential products) and current market (2022)
  - Review literature, standards, installed base, contractor, and manufacturer information
  - Provide a relative comparison and characterization of the cost/efficiency of a generic product
- Forecast of technology improvements that are projected to be available through 2050
  - Review trends in standards, product enhancements, and Research and Development (R&D)
  - Project impact of product improvements and enhancement to technology

The performance/cost characterization of end-use equipment developed in this study will assist EIA in projecting national primary energy consumption.

Methodology

Return to Table of Contents

Input from industry stakeholders, including government, R&D organizations, and manufacturers, was used to project product enhancements concerning equipment performance and cost attributes.

- Technology forecasting involves many uncertainties.
- Technology developments impact performance and cost forecasts.
- Varied sources ensure a balanced view of technology progress and the probable timing of commercial availability.
- Only currently published efficiency standards and regulations are considered when predicting technology developments; unpublished future regulatory action is not predicted.
- All costs are shown in 2022 dollars (2022$).
- Ranges, when given, represent the span of typical values for a given parameter (e.g., installed cost for equipment meeting the federal standard) not the highest and lowest available on the market.

U21806-MNSC-CE-0771-Att 4

Advanced Case Assumptions

Final

Return to Table of Contents

The Advanced Case and Reference Case both assume current level of effort for standards. However, the Advanced Case assumes an increase in market incentive and federal R&D. The general approach for the Advanced Case is outlined below.

- The Advanced Case considers future changes to product groups such as:
  - Product or component changes that are fully developed but have not yet been commercialized
  - Expected incremental improvements in existing technologies due to increased R&D
  - Increased adoption of existing higher efficiency technology options due to increased market incentives
- The Advanced Case did *not* include future changes to product groups that are due to:
  - Prototype technology changes or products that are in preliminary research that may have performance improvements but have only been demonstrated in theoretical calculations

Definitions

Return to Table of Contents

The following tables represent the current and projected efficiencies for residential and commercial building equipment ranging from the installed base in 2012 and 2018 (for commercial products) or 2015 and 2020 (for residential products) to the highest efficiency equipment that is expected to be commercially available by 2050, assuming incremental adoption. Below are definitions for the terms used in characterizing the status of each technology.

- Installed Base: Efficiency values are for those units installed and "in use" in that year. Cost values are for the typical new unit sold in that year.
- Current Standard: The minimum efficiency (or maximum energy use) that is required (allowed) by current U.S. Department of Energy (DOE) standards, when applicable.
- ENERGY STAR: The minimum efficiency that is required (or maximum energy use allowed) to meet the ENERGY STAR criteria, when applicable. The performance data that are presented are representative of certified products that just meet current ENERGY STAR specifications.
- Typical: Efficiency and cost values are for the average, or "typical," product being sold in the particular timeframe. This may represent either the shipments-weighted average product performance or the most common product on the market.
- High: Efficiency and cost values are for the product with the highest efficiency available in the particular timeframe.

Market Transformation

Return to Table of Contents

The market for the reviewed products has changed since this analysis was previously conducted.[1] These changes are noted and reflected in the efficiency and cost characteristics.

- In some categories the typical new product purchased today is more efficient than the average product in the installed base in 2012 (commercial) or 2015 (residential):
  - Residential sector: boilers, central air conditioners, room air conditioners, gas-fired furnaces (North), gas-fired furnaces (Rest of Country), oil-fired furnaces, electric resistance furnaces, heat pump water heaters, gas-fired instantaneous water heaters, natural gas cooktops, natural gas ovens, refrigerator-freezers, freezers, clothes dryers, clothes washers, and dishwashers
  - Commercial sector: gas-fired furnaces, oil-fired boilers, commercial rooftop heat pumps, commercial ground-source heat pumps, gas-fired instantaneous water heater, natural gas and electric ranges, griddles, and ovens
- More stringent Federal standards have taken effect for the following products:
  - Gas-fired and oil-fired boilers in 2021
  - Rooftop air conditioners and rooftop heat pumps in 2018
- Federal standards are slated to take effect in the coming years for the following products:
  - Central air conditioners, residential air-source heat pumps, gas-fired furnaces, oil-fired furnaces, gas-fired boilers, oil-fired boilers, rooftop air conditioners, and rooftop heat pumps in 2023
  - Portable air conditioners in 2025
- ENERGY STAR continues to raise the bar with revised criteria for:
  - Central air conditioners, residential air-source heat pumps, rooftop air conditioners, rooftop heat pumps, residential water heaters, and dishwashers in 2023

Note: The previous analysis is available in the EIA Technology Forecast Updates (2018) report.

Retail Equipment Cost (2022$)	1,300	1,300	1,080	1,200	1,220	1,390	1,220	1,390	1,220	1,390	1,220	1,390
Total Installed Cost (2022$)	2,880	2,880	3,690	4,130	4,150	4,320	4,150	4,320	4,150	4,320	4,150	4,320
Annual Maintenance Cost (2022$)	60	60	120	130	130	130	130	130	130	130	130	130

1. Typical input capacity is represented in terms of thousand British thermal units (kBtu) per hour (i.e., kBtu/h).
2. Electric consumption, represented in terms of kilowatt hours per year (kWh/y), accounts for the electricity consumption of components such as the furnace fan, draft inducer, and the ignitor. In some high efficiency products, this component also includes auxiliary equipment, such as condensate pumps and heat tape.
3. In the Residential Furnaces EERE 2022 Notice of Proposed Rulemaking (NOPR) Technical Support Document (TSD), an average lifetime of 22.5 years is calculated for gas-fired furnaces (North). Lifetime range was calculated using the Weibull Distribution in the Residential Furnaces EERE 2022 NOPR.

Note:
Models on the market can be either weatherized or non-weatherized. The majority (74%) are non-weatherized, and the values in the table use only non-weatherized data.
Electric consumption and cost values for 2022 and beyond are for a national sample and use the Residential Furnaces EERE 2022 NOPR Life-Cycle-Cost (LCC) spreadsheet.
Electric consumption and costs for the 2030, 2040, and 2050 high values are estimated based on the maximum-efficiency level analyzed in Residential Furnaces EERE 2022 NOPR, which is 98% annual fuel utilization efficiency (AFUE).
The current standard went into effect in November 2015.
ENERGY STAR V. 4.1 went into effect in February 2013.
The range for average life represents the span of typical values.

U21806-MNSC-CE-0771-Att 4

Final

Residential Gas-Fired Furnaces

Return to Table of Contents

- Current Federal standards for non-weatherized gas furnaces:
  - AFUE ≥ 80%
- ENERGY STAR V. 4.1 criteria for gas furnaces:
  - South: AFUE ≥ 90%
  - North: AFUE ≥ 95%
  - Furnaces must be equipped with electronically commutated fan motor and have less than or equal to 2.0% air leakage
- Most efficient unit currently available: 99.0% AFUE. The current market is nearly evenly split between non-condensing units (AFUE≤82%) and condensing units (AFUE≥90%).
- The maximum AFUE for non-condensing gas furnaces is 82%; above this level, the potential for exhaust gas condensation increases. This condensate is corrosive and requires cost restrictive corrosion resistant venting.
- High-efficiency condensing furnaces typically have high-grade stainless steel (AL 29-4C) heat exchangers.
- Many condensing furnaces are available as direct vent and sealed combustion systems, which do not use room air for combustion, but instead draw combustion air directly from outdoors.
- Depending on the location of the home, piping materials in use, and other considerations, condensing furnaces may need an acid neutralizer and/or lift pump for the condensate.
- Furnaces may contain permanent split capacitor (PSC) fan motors or electronically commutated motors (ECMs). The type of motor affects the electrical consumption of the furnace as well as the seasonal energy efficiency ratio (SEER) / energy efficiency ratio (EER) of the associated air conditioner.
  - The 2016 Energy Conservation Standards for Residential Furnace Fans Final Rule requires that all furnaces use ECM fans.
  - Most non-weatherized gas furnaces employ ECMs and can fully modulate rather than cycling on and off. Because they modulate, there is an increase in total fan-on time.

U21806-MNSC-CE-0771-Att 4

Residential Oil-Fired Furnaces

Final

Return to Table of Contents

- Current Federal standards:
  - AFUE ≥ 83%
  - ≤ 11 watts of electrical power when in standby and off modes (non-weatherized models only)
- ENERGY STAR V. 4.1 criteria: AFUE ≥ 85%
- Since the latent heat content of oil is lower than that for either propane or natural gas, oil-fired appliances can typically operate at a higher AFUE rating than comparable gas-fired appliances before condensation issues arise.
- Most efficient unit currently available: 96.7% AFUE – condensing units with tiny market share (<1%), due to market acceptance issues.
- Condensate from condensing oil furnaces is typically even more corrosive than that of gas-fired systems due to the higher sulfur content in fuel oil. Hence, condensing oil furnaces also likely require the use of an acid neutralizer.
- Oil-fired furnaces, like gas-fired furnaces, achieve condensing conditions through the use of a secondary heat exchanger. Typically, these secondary heat exchangers use a high-grade stainless steel (AL 29-4C).
- Sooting is an issue for all oil-fired appliances, but secondary heat exchangers, with their narrow passages, are even more prone to be plugged by soot. Because of this, condensing oil furnaces typically require frequent cleaning and maintenance.

Electric Consumption (kWh/y)[3]	197	506	282	506	527	502	506	502	506	502	506	502
Average Life (y)	20	20	20	20	20	20	20	20	20	20	20	20
	30	30	30	30	30	30	30	30	30	30	30	30
Retail Equipment Cost (2022$)	2,540	2,890	1,820	2,890	2,440	3,670	2,890	3,670	2,890	3,670	2,890	3,670
Total Installed Cost (2022$)	7,760	5,940	8,700	5,940	6,700	6,710	5,940	6,710	5,940	6,710	5,940	6,710
Annual Maintenance Cost (2022$)[4]	110	160	150	160	160	160	160	160	160	160	160	160

1. The 2020 AFUE is estimated based on EERE 2022 preliminary analysis, which estimates that gas-fired boilers with the highest market share in 2020 have an AFUE of 95%.
2. The 2030, 2040, 2050 projections are estimated based on the EERE 2022 preliminary analysis, which notes that majority of the market is expected to be condensing, if new standards are not implemented. The EERE 2022 preliminary analysis estimates a minimum efficiency of 95% AFUE for condensing units.
3. Electric Consumption accounts for the electricity consumption of auxiliary electrical components including circulating pump, the boiler pump (condensing boilers only), the draft inducer (if present), and the ignitor. It also accounts for the electricity consumption of auxiliary equipment such as a condensate pump and heat tape, which are sometimes installed with higher efficiency boilers. Additionally, it accounts for the additional cooling load due to heat loss from the boiler and water heater as a result of water heating during the cooling season.
4. Maintenance cost is the routine annual cost to the consumer of general maintenance for product operation. Maintenance cost is higher for condensing boilers for the inspection of condensate system and replacement of condensate neutralizer filter.

Note:
The current standard went into effect in January 2021.
ENERGY STAR V. 3.0 went into effect in December 2013.
Water boilers considered. Steam boilers also exist but make up a small percentage of the market.
The range for average life represents the span of typical values.

U21806-MNSC-CE-0771-Att 4

Final

Residential Gas-Fired Boilers

Return to Table of Contents

- Federal standard for gas-fired hot-water boilers (more common than steam):
  - AFUE ≥ 84%
  - Standard went into effect on January 21, 2021
- ENERGY STAR criteria: AFUE ≥ 90%
- Most efficient gas-fired boiler available: 96.4% AFUE
- Gas-fired boilers have lost market share to furnaces and heat pumps over the past 30 years.
- U.S. gas hot water boiler sales are split approximately 60/40 between condensing and non-condensing.[1] Condensing boilers typically have heat exchangers made of stainless steel, and non-condensing boilers typically have heat exchangers made of cast iron.
- Typically, condensing boilers are low-mass in construction with modulating burners, variable-speed inducer fan systems or sealed powered direct-vent combustion, multiple sensor technologies, and electronic ignition and control.
- Due to incentives and market pressure, the U.S. boiler industry has been shifting towards also providing condensing boilers. Most of these boilers are private-labeled products sourced from Europe, where the hydronic market is much bigger and condensing appliances are much more common and/or required by law.
- Most value-added components for condensing boilers are sourced abroad, even when the condensing boiler is assembled in North America (e.g., heat exchanger, gas valve, burner, sensors, and/or controls).

1. The 2020 AFUE is estimated based on EERE 2022 preliminary analysis, which estimates that oil-fired boilers with the highest market share in 2020 have an AFUE of 86%.
2. The 2030, 2040, 2050 projections are estimated based on the EERE 2022 preliminary analysis, which notes that majority of the market is expected to be at 86% AFUE, if new standards are not implemented.
3. Electric Consumption accounts for the electricity consumption of auxiliary electrical components including circulating pump, the ignitor, condensate pump, and heat tape, which are sometimes installed with higher efficiency boilers. Additionally, it accounts for the additional cooling load due to heat loss from the boiler and water heater as a result of water heating during the cooling season.
4. Maintenance cost is the routine annual cost to the consumer of general maintenance for product operation.

Note:
The current standard went into effect in January 2021.
ENERGY STAR V. 3.0 went into effect in December 2013.
Water boilers considered. Steam boilers also exist but make up a small percentage of the market.
The range for average life represents the span of typical values.

U21806-MNSC-CE-0771-Att 4

Residential Oil-Fired Boilers

Final

Return to Table of Contents

- Federal standard for oil-fired hot-water boilers (more common than steam):
  - AFUE ≥ 86%
  - Standard went into effect on January 21, 2021
- ENERGY STAR criteria: AFUE ≥ 87%
- Most efficient oil-fired boiler available: 88% AFUE
- Since the latent heat content of oil is lower than that for either propane or natural gas, oil-fired appliances can typically operate at a higher AFUE rating than comparable gas-fired appliances before condensation issues arise.
- Oil boilers have heat exchangers made of cast iron or steel.
- No condensing oil-fired boilers currently exist in the U.S. market. The high sulfur content in fuel-oil causes heat exchanger fouling if the flue gases from an oil-fired boiler were to condense. As a result, condensing oil-fired boilers would require more frequent maintenance and repair, if installed.
- Advanced Case: Increased incentives move typical efficiency products to ENERGY STAR levels by 2030. The current typical efficiency product is at 86% AFUE, while ENERGY STAR is at 87%, with only a small difference in costs. It is expected that with more market incentives, manufacturers will produce more products that can be ENERGY STAR certified at the 87% level.
- Advanced Case: High efficiencies expected to be at 95% AFUE for condensing oil-fired boilers. These models are already seen in Europe and would be expected to re-enter the U.S. market as well.

Residential Electric Resistance Furnaces

Return to Table of Contents

- Federal standards for electric furnaces:
  - AFUE ≥ 78%
  - Standby and off mode power consumption ≤ 10 watts
- According to preliminary Residential Energy Consumption Survey (RECS) data released May 2022, electric central warm-air furnaces are the main source of space heating in approximately 17.5 million U.S. homes or about 14%.
- Electric furnaces range in capacity from 10 to 25 kW (34 to 85 kBtu/h), with 20 kW (68 kBtu/h) being the typical for units on the market.
- Electric resistance furnaces are considered near 100% efficient because there is no flue heat loss, and any jacket losses are contained within the home.
  - ASHRAE Standard 103, the test method for furnaces incorporated by reference into the federal test procedure, specifies that for electric furnaces AFUE = 100 – 1.7 x jacket losses. Jacket losses can be determined either through testing or assumed to be 1%. Thus, the minimum AFUE of electric furnaces is 98.3%.

Final

Residential Electric Resistance Unit Heaters

Return to Table of Contents

- Electric resistance unit heaters include electric wall and baseboard heaters. Plug-in space heaters are not included.
- There are currently no federal efficiency requirements for electric resistance unit heaters.
- According to preliminary RECS data released May 2022, electric resistance unit heaters are the main source of space heating in approximately 8.25 million U.S. homes or about 7%.
- Electric heaters range in capacity from 500 to 2,500 watts (1.7 to 8.5 kBtu/h), with 1,500 watts (5.1 kBtu/h) being the most typical for units on the market.
- Electric resistance heating is considered 100% energy efficient; all incoming electric energy is converted to heat.

Residential Central Air Conditioners

Final

Return to Table of Contents

- The previous standards took effect in 2015; amended standards for all product classes went into effect in January 2023.
  - Amended standards are based on new metrics (SEER2, EER2).
  - SEER2 values are generally expected to be lower than SEER because a higher external static pressure is required during testing, which reduces measured performance.
- Systems installed in the Southwest (CA, AZ, NM, and NV) must also meet an EER standard that varies by cooling capacity and system configuration.
- Advanced Case: Due to increases in R&D, improvements in current technology (e.g., more cost-effective variable speed technology) are expected to increase efficiency without substantially increasing costs.

1. RAC EERE 2022 NOPR has analysis for combined energy efficiency ratio (CEER) of 16 Btu/Wh, which represents variable speed room air conditioners. However, maximum CEER identified in DOE's Compliance Certification Database (CCD) in August 2022 was 15.7 Btu/Wh. Accordingly, the high CEER is estimated to be 15.7 for 2022 and beyond. Cost values for a representative unit with a CEER of 16 Btu/Wh were used.
2. The 2030, 2040, 2050 projections are estimated based on RAC EERE 2022 NOPR, which notes that in the absence of no new standards, room air conditioners with a CEER of 12 Btu/Wh are expected to have the maximum market share.
3. Maintenance costs are negligible per RAC EERE 2011 and RAC EERE 2022 NOPR.

Note:
All values are for the most common product class, Product Class 3 (without reverse cycle, with louvered sides, and 8,000 to 13,999 Btu/h).
The current standard went into effect in June 2014.
ENERGY STAR V. 4.2 went into effect in October 2015.
Ranges represent the span of typical values for a given parameter (for example, installed cost for equipment meeting the federal standard) not the highest and lowest available on the market.

U21806-MNSC-CE-0771-Att 4

Residential Room Air Conditioners

Final

Return to Table of Contents

- Analyzed the most common type of room air conditioners: louvered sides (window air conditioners) without reverse cycle and having cooling capacity of 8,000–13,999 Btu/h (DOE Product Class 3).
- Federal standards for Product Class 3:
  - CEER ≥ 10.9 (beginning June 1, 2014)
- CEER incorporates energy use in cooling mode and standby and off modes.
- ENERGY STAR V. 4.2 criteria for Product Class 3:
  - CEER ≥ 12.0 (effective October 26, 2015)
- Efficiency improvements in room air conditioners are attained by:
  - Higher efficiency compressor and fan motors (including variable speed motors), and
  - An increased heat transfer area in the evaporator and condenser using larger heat exchangers, finer fin spacing, micro-channel heat exchangers, and similar design options.
- Advanced Case: Due to increases in R&D, improvements in current technology (e.g., more efficient motors and compressors, larger cross-section heat exchangers, adoption of variable speed technologies) are expected to increase efficiency with corresponding increases in cost.

Lifetime range represents span of typical values.

U21806-MNSC-CE-0771-Att 4

Residential Swamp Coolers

Final

Return to Table of Contents

- Evaporative cooling (i.e., "swamp coolers") is a technology that takes advantage of water evaporation to cool incoming air. Energy is required to change water from a liquid to a vapor (i.e., the heat of vaporization), and in doing so, temperature of the air is reduced. Evaporative cooling is best suited for hot, dry climates.
- Swamp coolers come in a variety of different configurations, including centrally ducted units that are mounted outside a building or roof; window evaporative coolers that are window-mount units that pull in warm outdoor air, pass it through wet media to remove heat, and blow out the cooled air; or portable plug-in units. Window units were considered for this analysis due to the high model share count on distributor websites.
- The U.S. Environmental Protection Agency (EPA) has cautioned against using swamp coolers in wildfire-impacted areas in smoky conditions because it can result in more smoke bring brought inside.
- Swamp coolers are not a DOE-covered product.
- Swamp cooler metrics include power of the fan/blower, measured in horsepower (hp), and air flow rate, measured in cubic feet per minute (CFM).

	150	150	150	150	150	150	150	150	150	150	150	150	150	150	150	150

1. Values shown are for split-system units in the 36 kBtu/h (3-ton) size class. Costs and efficiency levels are for "blower-coil" systems, meaning they include a blower. Note coil-only systems were analyzed for residential central air conditioners, which is why the "High" SEER levels are higher for heat pumps than for air conditioners.
2. In 2023, new energy conservation standards for Residential Central Air Conditioners and Heat Pumps took effect. The new standards specify different metrics for Air-Source Heat Pumps (SEER2 and heating seasonal performance factor 2 (HSPF2)). SEER to SEER2 and HSPF to HSPF2 conversions were determined using the RESNET website.
3. Annual maintenance include preventative maintenance and services provided by HVAC professionals for maintaining product operation. Examples include, calibrate and level thermostat, clean filters, clean indoor and condenser coil, flush/treat condensate drain with anti-algae, inspect condenser coil, monitor operating pressure of refrigerant, inspect fan blade, etc.
4. High costs derived from developing a cost-efficiency curve between retail/installed costs and SEER.

Note:
The previous standard went into effect in January 2015. The current standard went into effect in January 2023.
ENERGY STAR V. 5.0 went into effect in September 2015. ENERGY STAR V. 6.1 went into effect in January 2023.
Ranges represent the span of typical values for maintenance costs.
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (15.88, 2, 1).

U21806-MNSC-CE-0771-Att 4

Residential Air-Source Heat Pumps

Return to Table of Contents

- The previous standards took effect in 2015; amended standards for all product classes went into effect in January 2023.
  - Amended standards are based on new metrics (SEER2, EER2, HSPF2).
  - SEER2 values are generally expected to be lower than SEER because a higher external static pressure is required during testing, which reduces measured performance.
- High efficiency cooling does not necessarily correlate with high efficiency heating. The range of SEER–HSPF combinations is very broad.
- Heat pumps are generally sized to meet the cooling load of the house. When the heating load exceeds heat pump heating capacity, electric resistance heat is used to supplement.
- Variable-speed compressors improve efficiency of heat pumps by reducing cyclic losses and by operating above their nominal speed, boosting heating capacity, and reducing the need for supplementary electric resistance heat.
- In addition to meeting the SEER2 and HSPF2 requirements, air source heat pumps must demonstrate low ambient performance to earn the Cold Climate designation by meeting the following:
  - Coefficient of Performance (COP) at 5 degrees Fahrenheit (°F) ≥ 1.75, measured in accordance with Appendix M1 $H4_2$ test
  - Percent of Heating Capacity at 5 °F ≥ 70% of that at 47 °F, with the 5 °F capacity measured per Appendix M1 $H4_2$ test and the 47 °F capacity measured as the nominal heating capacity per Appendix M1 (i.e., from the Appendix M1 $H1_N$ test for units having a variable-speed compressor where the compressor speed shall be the maximum speed that the system controls would operate at 47 °F, otherwise from the Appendix M1 $H1_2$ test)
  - Perform a controls verification procedure (CVP) to confirm that the above performance metrics measured at the Appendix M1 low ambient test point at 5 °F are achieved by the native controls operating as they would in a customer's home
- Advanced Case: Due to increases in R&D, improvements in current technology (e.g., more cost-effective variable speed technology) are expected to increase efficiency without substantially increasing costs.

Residential Air-Source Heat Pumps

Return to Table of Contents

From 2000 to 2005 annual shipments increased nearly 60% to 2.1 million units, then dropped and leveled off around 1.7 million units. In 2014 annual shipments surpassed the 2005 peak and have been increasing uniformly since then.

Residential Central Air Conditioners and Air-Source Heat Pumps

Final

Return to Table of Contents

- Principal energy efficiency drivers for central air conditioners and heat pumps:
  - Heat exchanger (surface area, number of tube rows)
  - Compressor (type and single-stage vs. two-stage vs. variable-speed operation)
  - Fan motor choices (PSC vs. ECM fan motors on inside and outside)
  - Control choices (i.e., piston, thermal, and electronic expansion valves)
- When the heat pump or air conditioner's capacity exceeds the heating or cooling load, the unit starts and stops more frequently, causing wear and tear on the components and an overall loss of efficiency. Multi-stage and/or variable-speed compressors can help, as does sophisticated refrigerant management.
- Typical high-efficiency unit (≥ 16 SEER) has very large heat exchanger, ECM evaporator fan motor, and two-stage scroll compressor.
- Variable-speed compressor technology typically leads to a significant SEER boost, making possible high-SEER condensing units with smaller heat exchangers, and thus, smaller enclosures.
- Efficiency levels > 21 SEER made possible through combining existing large heat exchangers with variable-speed compressors, ECM fan motors, and electronic expansion valves.

Residential Ductless Mini-Split Air-Source Heat Pumps

Return to Table of Contents

- Ductless systems can be useful in "spot cooling" certain high-use areas of a home, such as a living room, bedroom, or office.
- Mini-split heat pumps are generally more efficient (often > 20 SEER) and smaller in cooling capacity (often ≤ 24 kBtu/h) compared to split-system heat pumps.
  - A mini-split heat pump could be equal in capacity and efficiency to a split-system heat pump as there are no inherent design changes between split-system and mini-split heat pumps, aside from the ductwork. Mini-split heat pumps tend to be more efficient and smaller in capacity due to their prevalence for spot cooling, but the same technologies are used between the two product categories.
- Due to the similarities in design, cost estimations were determined based on smaller capacity (24 kBtu/h) split-system heat pumps and Gordian's RSMeans Data – Building Construction Costs 2023. Efficiency data was analyzed using the AHRI directory, which provides disaggregation of data on the basis of ducted and ductless heat pumps.
- Annual maintenance covers the same services identified for air-source heat pumps.

Annual Maintenance Cost (2022$)	90	90	90	90	90	90	90	90	90	90	90	90

1. COP values listed are assessed at a "ground loop" test condition, which is representative of closed loop ground source heat pumps (GSHP) operating conditions. However, DOE sets standards at a "water loop" test condition. The AHRI directory lists COP ratings at both sets of test conditions and is used to convert between them where necessary.
2. EER values listed are assessed at a full-load "ground loop" test condition, which is representative of closed loop GSHP operating conditions. However, DOE sets standards at a full-load "water loop" test condition. The AHRI directory lists EER ratings at all sets of test conditions and is used to convert between them where necessary.

Note:
Residential and commercial GSHPs are very similar - the main difference in data presented is the different capacity (3-ton vs. 4-ton) and slightly higher installation costs for commercial GSHP. DOE does not distinguish between residential and commercial units in its regulations.
Current standards went into effect on October 9, 2015. COP and EER ratings are converted from the "water loop" test condition to "ground loop."
ENERGY STAR V. 3.2 went into effect January 1, 2012.
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (17.04, 1.64, 1).

U21806-MNSC-CE-0771-Att 4

Residential Ground-Source Heat Pumps

Final

Return to Table of Contents

- Heating COP does not correlate with cooling EER.
- The ENERGY STAR criteria for water-to-air ground-source heat pumps are:

Type	Heating COP	Cooling EER
Closed Loop	3.6	17.1
Open Loop	4.1	21.1
Direct Expansion	3.6	16

- The most common GSHP is a closed-loop system in which water or an anti-freeze solution is circulated through plastic pipes buried underground. Open loop systems that employ ground water or surface water (e.g., open well, pond, lake) are used in some parts of the country, but water supply and water quality issues impose limitations on such applications.
- Installation cost is for a closed loop system and includes necessary accessories. The ground loop heat exchanger represents a majority of the installation cost. Installed costs for these systems vary widely.
- Variable speed ECMs improve performance on high-end models.
- Advanced Case: GSHP are already highly efficient and have not changed much in terms of efficiency in recent years. With increased R&D, it is anticipated that the equipment and installation costs will be reduced over time, but efficiency will likely stay the same.

Residential Natural Gas Heat Pumps

Return to Table of Contents

- Residential natural gas heat pumps are not currently subject to DOE regulations. The California Energy Commission's (CEC) Title 24, Part 6 Section 112 does indicate cooling efficiency requirements for natural gas heat pumps.
- Natural gas heat pumps are much more popular in other parts of the world, such as Europe. Gas-fired cooling equipment currently comprises less than 1% of the residential air conditioning/heat pump market in the U.S.
- Currently, Robur is the predominant manufacturer of residential-sized natural gas heat pumps with sales operations in the U.S.. Robur units are 5-ton nominal cooling capacity, a size typically associated with larger homes. Since only one product is available, no mid-level or high efficiency categories are included in this analysis.
- The data represents air-source absorption heat pumps. Gas engine-driven vapor compression heat pumps are available in other parts of the world; York formerly offered the Triathlon gas engine-driven heat pump in the U.S. It is possible to couple either technology to the ground (ground-source) rather than the atmosphere (air-source).
- The absorption heat pump is a gas-fired, ammonia-water absorption cycle, combined with a high-efficiency low-pressure boiler integrated into one outdoor unit.
- The cooling efficiency of a gas-fired air-source absorption heat pump is considerably lower than for an electric air-source heat pump. Heating efficiency of an air-source heat pump (electric or gas-fired absorption) decreases as outdoor temperature decreases; however, the gas-fired absorption heat pump recovers waste heat from the combustion process to improve heating efficiency.

1. For 2015, assumed EPA default efficiencies, which were used by EPA to approximate the efficiency of stoves before the 2015 EPA rule required efficiency testing.
2. For 2020, assumed same efficiencies as estimated for 2022 given the most recent EPA rule went into effect in May 2020.
3. The 2022 High value is the highest EPA certified efficiency. The 2022 Typical value is the average of EPA certified efficiencies.
4. For 2030-2050, it is assumed that the same conditions as current would persist because no impending efficiency requirements are expected from EPA, given recency of 2020 rulemaking and current market factors.
5. Efficiency includes combustion and heat transfer efficiency and is based on the higher heating value (HHV) of the fuel.
6. Installed costs include the cost of hearth and stainless-steel chimney liner - materials and labor.
7. For catalytic stoves, annual maintenance cost includes periodic cost of replacing the catalytic combustor.

Note:
The range for average life represents the span of typical values.

U21806-MNSC-CE-0771-Att 4

Final

Residential Cordwood Stoves

Return to Table of Contents

- Residential cordwood stoves that must meet EPA particulate limits fall into two broad classes based on whether they use a catalyst for air treatment. Catalytic wood stoves use a catalytic combustor to reduce emissions from the combustion air. Non-catalytic wood stoves use baffles and introduce secondary air above the flames to enable more complete combustion and reduce emissions.
- In 2015, EPA published an update to its New Source Performance Standards (NSPS), decreasing the emissions limit (previously set by 1988 EPA rule) to 4.5 grams per hour (g/h) for both catalytic and non-catalytic stoves. The new rule did not institute efficiency standards but required that manufacturers test and certify the efficiency of their stoves. This standard took full effect on January 1, 2016.
- In 2020, the NSPS limit for new room heaters was lowered to 2.5 g/h if tested with cord wood.
- Prior to the 2015 rule, manufacturers could either submit efficiency data from laboratory testing or certify with the default efficiency value designated by EPA. EPA's default efficiency values were 63% for non-catalytic wood stoves and 72% for catalytic wood stoves. Under this system, few manufacturers submitted efficiency test data to EPA.
- Multiple test standards are commonly used to assess stove efficiency, and data from product literature does not generally identify the efficiency test method.
- It is not possible to determine performance trends based on construction or configuration (e.g., cast iron vs. plate steel, powered blowers vs. no blowers, etc.) trends in specific equipment type or construction based on published efficiencies. Further, EPA certification data shows no significant relationship between emissions and heating efficiency.
- Cordwood stoves require chimneys for venting combustion gases. Whether conventional masonry chimneys are used or metal chimney liners, these add considerable cost to the overall system. Accordingly, installed costs can be twice that of the wood stove itself.

- It is not possible to determine performance trends based on construction or configuration (e.g., cast iron vs. plate steel, powered blowers vs. no blowers, etc.) trends in specific equipment type or construction based on published efficiencies. Further, EPA certification data shows no significant relationship between emissions and heating efficiency.
- Wood pellet stoves may be able to be direct vented to the outdoors, eliminating the need for a chimney. This reduces the overall system cost as compared to a cord wood stove. However, they do use electricity to power the pellet feeder, the combustion air fan, and the blower. In the event of a power outage, a pellet stove can not operate without some back-up source of electricity (e.g., battery) .

	1,240	2,880	1,690	1,690	1,850	3,130	3,160	1,690	3,130	1,690	3,130	1,690	3,130
Annual Maintenance Cost (2022$)[2]	20	20	20	20	20	20	20	20	20	20	20	20	20

1. Analysis is based on an average of medium and high draw pattern units, as this is most reflective of the market.
2. Maintenance includes manufacturer recommendation for the water heater to be drained and flushed annually to minimize deposition of sediment, maintain operating efficiency, and prolong product life. Available evidence indicates that this is performed in 10% of households.

Note:
Ranges represent the span of typical values.
Current standards went into effect April 16, 2015.
ENERGY STAR V. 4.0 went into effect January 5, 2022
ENERGY STAR V. 5.0 will go into effect April 18, 2023
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (15.1, 1.76, 1).

U21806-MNSC-CE-0771-Att 4

Residential Gas-Fired Storage Water Heaters

Final

Return to Table of Contents

- The equations for Federal Standards and the voluntary ENERGY STAR requirements, if applicable, are:

Volume Range	Draw Pattern	Federal standard[1]	Federal minimum UEF for typical sizes	ENERGY STAR
≥ 20 gal and ≤ 55 gal	Very Small	UEF=0.3456-(0.002*Gal)	No models on the market	NA
	Low	UEF=0.5982-(0.0019*Gal)	0.54 for a 29-gallon water heater	NA
	Medium	UEF=0.6483-(0.0017*Gal)	0.58 for a 38-gallon water heater	0.64
	High	UEF=0.692-(0.0013*Gal)	0.64 for a 48-gallon water heater	0.68
> 55 gal and ≤ 100 gal	Very Small	UEF=0.647-(0.0006*Gal)	No models on the market	NA
	Low	UEF=0.7689-(0.0005*Gal)	No models on the market	NA
	Medium	UEF=0.7897-(0.0004*Gal)	No models on the market	0.78
	High	UEF=0.8072-(0.0003*Gal)	No models on the market	0.80

- There are currently no models on the market above 55 gallons (gal) due to the high UEF, which would require using condensing or gas-fired heat pump (e.g., absorption) technology to achieve.
- The cost of installation is typically $600 to $1200, which exceeds that of electric water heaters. This difference can be attributed to multiple differences; for example, gas-fired heaters require an extra 1.5 hours of labor for 2 plumbers.
- Condensing units are high efficiency and use PVC venting instead of stainless-steel. Condensing units also use an electrical supply for electronic ignition and power venting. Some building codes require condensate neutralizer filters.
- Advanced Case: Condensing gas-fired storage water heaters are expected to dominate the market by 2030, with corresponding price increases.

Annual Maintenance Cost (2022$)[2]	210	210	210	210	210	210	210	210	210	210	210

1. Analysis is based on an average of medium and high draw pattern units, as this is most reflective of the market.
2. Oil-fired storage water heaters are typically cleaned and maintained under maintenance contracts. The annual cost of typical maintenance is based on maintenance contract prices from different oil-fired product suppliers as specified in the CWH EERE 2022 Preliminary Analysis.

Note:
Ranges represent span of typical values.
Current standards went into effect April 16, 2015.
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (16.2, 1.70, 1).

U21806-MNSC-CE-0771-Att 4

Residential Oil-Fired Water Heaters

Final

Return to Table of Contents

- The equations for Federal Standards and the voluntary ENERGY STAR requirements, if applicable, are:

Volume Range	Draw Pattern	Federal standard[1]	Federal minimum UEF for typical sizes	ENERGY STAR
≤ 50 gal	Very Small	UEF=0.2509-(0.0012*Gal)	No models on the market	NA
	Low	UEF=0.533-(0.0016*Gal)	No models on the market	NA
	Medium	UEF=0.6078-(0.0016*Gal)	No models on the market	NA
	High	UEF=0.6815-(0.0014*Gal)	0.64 for a 29-gallon water heater	NA

- There are no ENERGY STAR requirements for oil-fired storage water heaters.
- Annual shipments of residential oil-fired storage water heaters are approximately 4,000, which is less than 1% of shipments of residential gas-fired storage water heaters.
- Oil-fired storage water heaters often have smaller tanks with larger input ratings relative to natural gas-fired and electric storage water heaters.
- No condensing residential oil-fired storage water heaters currently exist in the U.S. market. Condensing oil-fired water heaters are generally not considered technologically feasible because the sulfur content in fuel oil leads to the condensate becoming corrosive.
- Residential oil-fired water heaters utilize power burners and have at least some level of electrical power consumption.
- The most efficient models on the market use a proprietary "turbo-flue" design to increase heat transfer to water.

	940	1,290	1,310	1,310	1,430	1,310	1,430	1,310	1,430	1,310	1,430
Annual Maintenance Cost (2022$)[2]	20	20	20	20	20	20	20	20	20	20	20

1. Beginning in 2016, the efficiency metric for water heaters changed from energy factor (EF) to UEF based on DOE test procedures. The UEF values for the installed base in 2015 are converted values equivalent to 0.90 EF. Analysis is based on an average of low and medium draw pattern units, as this is most reflective of the market.
2. Similar to gas-fired and oil-fired storage water heaters, manufacturers recommend that electric storage water heaters be drained and flushed annually to minimize deposition of sediment, maintain operating efficiency, and prolong product life. The available evidence indicates that this practice is done in 10% of households.

Note:
Ranges represent span of typical values.
Current standards went into effect April 16, 2015.
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (15.7, 1.57, 1).

U21806-MNSC-CE-0771-Att 4

Residential Electric Resistance Storage Water Heaters

Final

Return to Table of Contents

- The equations for Federal Standards and the voluntary ENERGY STAR requirements, if applicable, are:

Volume Range	Draw Pattern	Federal standard[1]	Federal minimum UEF for typical sizes	ENERGY STAR
≥ 20 gal and ≤ 55 gal	Very Small	UEF=0.8808-(0.0008*Gal)	No models on the market	2.00
	Low	UEF=0.9254-(0.0003*Gal)	0.92 for a 27-gallon water heater	2.00
	Medium	UEF=0.9307-(0.0002*Gal)	0.92 for a 45-gallon water heater	2.00
	High	UEF=0.9349-(0.0001*Gal)	0.93 for a 50-gallon water heater	2.00
> 55 gal and ≤ 120 gal	Very Small	UEF=1.9236-(0.0011*Gal)	No models on the market	2.20
	Low	UEF=2.0440-(0.0011*Gal)	No models on the market	2.20
	Medium	UEF=2.1171-(0.0011*Gal)	2.05 for a 58-gallon water heater	2.20
	High	UEF=2.2418-(0.0011*Gal)	2.15 for a 80-gallon water heater	2.20

- The federal standards for residential electric storage water heaters apply to both electric resistance storage water heaters and heat pump water heaters.
  - The Federal standard levels for the ≤ 55-gallon range are achievable through electric resistance and heat pump technology.
  - The Federal standards for the > 55-gallon range and all ENERGY STAR levels are only achievable through heat pump technology.
- Typical storage volumes range from 25-55 gallons for electric resistance storage water heaters and 45-80 gallons for heat pump water heaters (HPWHs).

Annual Maintenance Cost (2022$)[3]	20	20	20	20	20	20	20	20	20	20	20

1. Analysis is based on an average of low and medium draw pattern units, as this is most reflective of the market.
2. It is expected that costs for HPWHs will decrease over time as these products become more common. This analysis estimates these cost decreases for the higher range of costs.
3. For heat pump water heater design options, DOE assumed higher maintenance cost to take into account annual cleaning of the air filter, preventative maintenance cost to check the evaporator and refrigeration system, inspection of the condensate withdrawal system, and replacement of the condensate neutralizer filter, if applicable. However, this maintenance is estimated to occur in only 10% of households, so overall maintenance cost is similar to that of other electric resistance water heaters.

Note:
Ranges represent span of typical values.
ENERGY STAR V. 4.0 went into effect January 5, 2022.
Assume same lifetime as electric resistance water heaters.

U21806-MNSC-CE-0771-Att 4

Residential Heat Pump Water Heaters

Final

Return to Table of Contents

- Technology improvements have advanced efficiency and reliability, but the high first-cost and lack of awareness among consumers and contractors still precludes high-volume market penetration.
- New Federal standards that came into effect in April 2015 effectively mandate heat pump technology for electric storage water heaters with storage volume > 55 gallons.
- Integrated models are the most common configuration for residential HPWHs. Several major water heater manufacturers produce such models, and other competitors offer integrated or add-on units (for existing electric or indirect storage water heaters).
- Sales are estimated to be driven partly by rebates and tax credits at the utility, local, state, and Federal level.
- Resistive heating elements are virtually 100% efficient, but there is a jump in efficiency when heat pump technology is adopted because heat pumps' COP are usually between 2.5 and 4.
- Heat pumps raise the water temperature more slowly than resistive heating elements, so most models use backup resistive elements along with the heat pump when hot water demand is high. Most HPWHs allow the consumer to control whether resistive elements are used in periods of high demand (e.g., "hybrid mode" or "heat pump only mode").

Residential Solar Water Heaters

Final

Return to Table of Contents

Same as Reference Case

DATA	2015	2020	2022		2030	2040	2050
	Installed Base	Installed Base	ENERGY STAR V. 4.0	Typical	Typical	Typical	Typical
Typical Capacity (ft^2)[1]	42	42	40	40	40	40	40
	65	65	54.4	54.4	54.4	54.4	54.4
Solar Uniform Energy Factor (SUEF)[2]	3.0	3.0	3.0	99.0	99.0	99.0	99.0
Average Life (y)	15	15	15	15	15	15	15
	30	30	30	30	30	30	30
Retail Equipment Cost (2022$)	7,710	7,710	6,430	6,430	6,430	6,430	6,430
Total Installed Cost (2022$)	10,650	10,650	8,060	8,060	8,060	8,060	8,060
Annual Maintenance Cost (2022$)[3]	80	80	80	80	80	80	80

1. Capacity selections are based on the range observed from medium draw units in the ENERGY STAR database. Medium draw represented the largest portion of units.
2. An SUEF of 3.0 is the required threshold for ENERGY STAR certification, yet a value of 99 was the most common observed SUEF among medium draw units. Note that an SUEF of 99 indicates that no backup heating was required for the applicable draw pattern, and all energy was provided by the solar collector. Since SUEF is a measure of hot water energy out divided by electrical or gas backup energy in, it will be infinite for cases where the collector provides all the hot water needed for the draw pattern – the Solar Rating and Certification Corporation's (SRCC's) OG-300 software is written to assign an SUEF of 99 to this case.
3. Annual maintenance is expected to be 0.5% to 1% of the total installation for 2022, 2030, 2040, and 2050.

Note:
ENERGY STAR V. 4.0 went into effect January 5, 2022.

U21806-MNSC-CE-0771-Att 4

Residential Solar Water Heaters

Final

Return to Table of Contents

- Solar water heaters are not subject to federal energy conservation standards. The ENERGY STAR requirements are:

Applicable Products	Backup Fuel	ENERGY STAR Requirement	Test Method
Whole-home solar units	Gas	SUEF ≥ 3.0	ICC 900/SRCC 300-2020 Solar Thermal System Standard, Appendix A: Solar Uniform Energy Factor Procedure for Solar Water Heating Systems
	Electric	SEF ≥ 1.8	

- Solar water heaters can be either active or passive. An active system uses an electric pump to circulate the heat transfer fluid; a passive system has no pump. Most solar water heaters in the U.S. are the active type.
- Solar water heaters are also characterized as open loop (also called "direct") or closed loop (also called "indirect"). An open-loop system circulates household (potable) water through the collector. A closed-loop system uses a heat transfer fluid (water or diluted antifreeze, for example) to collect heat and a heat exchanger to transfer the heat to household water. Direct systems were observed as the most common product type and subject of this analysis.
- In 2020, stakeholders from the solar thermal industry developed the Solar Uniform Energy Factor (SUEF) Specification for solar water heaters to align with the UEF metric used by DOE for other water heating technologies.
- SUEF is also the metric used by the current ENERGY STAR Specification, and it replaced the Solar Energy Factor (SEF) metric.
- Over two-third of the current solar water heater market is in the southern or western U.S. (including Hawaii). A collector area of 42 square feet (ft^2) would be typical for these areas. Colder areas of the U.S. would require a larger collector (e.g., 65 ft^2).
- Installed costs are higher for colder areas where larger collectors are required. Costs also vary widely depending on collector quality, type of system, and site-specific characteristics.

	High	UEF=0.81	0.81	0.87

- The ENERGY STAR levels require the use of condensing technology.
- All of the major water heater manufacturers now offer an instantaneous water heater model.
- The maintenance costs include cleaning the water inlet filter and the heat exchanger of mineral deposits and replacing the water valve approximately once every five years for all instantaneous water heaters.
- When replacing a storage water heater with an instantaneous water heater, there are significant additional costs to upsize the gas supply line to ¾ inch from the typical ½ inch and change the venting.
- Advanced Case: Increased market incentives are expected to drive further adoption of condensing products, thereby raising the typical efficiency, while increased R&D is expected to improve cost.

Same as Reference Case

DATA	2015	2020	2022			2030		2040		2050	
	Installed Base	Installed Base	Current Standard	Typical	High	Typical	High	Typical	High	Typical	High
Representative Input Rate (kW)	3.5	3.5	3.5	3.5	3.5	3.5	3.5	3.5	3.5	3.5	3.5
Uniform Energy Factor (UEF)[1]	0.96	0.96	0.91	0.96	0.98	0.96	0.98	0.96	0.98	0.96	0.98
Average Life (y)	20	20	20	20	20	20	20	20	20	20	20
Retail Equipment Cost (2022$)	260	260	260	260	260	260	260	260	260	260	260
Total Installed Cost (2022$)	520	520	520	520	520	520	520	520	520	520	520
Annual Maintenance Cost (2022$)[2]	90	90	90	90	90	90	90	90	90	90	90

1. Analysis is based on an average of low, medium, and very small draw pattern units, as this is most reflective of the market.
2. Annual maintenance costs not provided in CWH EERE 2022 Preliminary Analysis. Maintenance costs determined from the following calculation: GIWH - (GSWH - ESWH) - i.e., the difference factor in maintenance between gas and electric storage heat pumps applied to gas instantaneous heat pumps.

Note:
Current standards went into effect April 16, 2015.
Assume same lifetime as gas-fired instantaneous water heaters.

Residential Electric Instantaneous Water Heaters

- The Federal standards are:

Volume Range	Draw Pattern	Federal standard[1]	Federal minimum UEF for typical sizes
<2 gal	Very Small	UEF=0.91	0.91
	Low	UEF=0.91	0.91
	Medium	UEF=0.91	No models on the market
	High	UEF=0.92	No models on the market

- Electric instantaneous water heaters use electric resistance heating elements to heat water when there is a demand. Resistive heating elements are virtually 100% efficient, and the small storage capacities of these products means that they do not lose significant amounts of heat to the environment.
- The federal standards for these products require UEFs of 0.91 for very small, low, and medium draw pattern models and 0.92 for high draw pattern models.
- Most products currently on the market are in the very small draw pattern or the low draw pattern because electric resistance elements can only supply a limited quantity of heat on an instantaneous basis due to circuit amperage limitations.
- Many products are designed for point-of-use applications, such that the water heater only supplies water to one faucet or showerhead.

Residential Refrigerator-Freezers

Final

Return to Table of Contents

- Current Federal standards[1]:
  - Compliance required beginning September 15, 2014
  - Models divided into 32 product classes based on size (standard or compact), location of freezer (top, bottom, or side), type of defrost (automatic or manual), installation configuration (freestanding or built-in), and presence and configuration (through-the-door or inside cabinet) of automatic icemaker
  - Limits on annual electricity consumption expressed as functions of adjusted volume[2]
  - New product classes for built-in units
  - Amount by which standards are tightened varies by product class
- ENERGY STAR criteria limit annual electricity consumption to 10% less than the Federal standard
- Energy efficiency opportunities for refrigerators include:
  - More efficient compressor, including variable speed compressors
  - Brushless direct current (DC) fan motor (also known as ECM motor)
  - Variable defrost
  - Larger condenser
  - Dual evaporators
  - Vacuum-insulated panels
  - Refrigerants (Isobutane vs. R134a)
- Advanced Case: Increased market incentives will push product sales towards the ENERGY STAR level, but the technologies used to meet ENERGY STAR are already well-known and prices will likely not rise as manufacturing volumes increase at higher efficiencies.

[1]Energy Conservation Standards for Residential Refrigerators, Refrigerator-Freezers, and Freezers. 10 CFR 430.32(a).
[2]Adjusted Volume (AV) = (Fresh Volume) + 1.76 × (Freezer Volume)

Annual shipment volumes have rebounded from a sharp decline between 2006 and 2009, reaching approximately 11.4 million units in 2020.

Annual Maintenance Cost (2022$)[4]	10	10	10	10	10	10	10	10	10	10	10	10

1. Product Class 9 is used for this analysis (Upright freezers with automatic defrost).
2. The volume shown here is the nominal volume, not the adjusted volume, which is used to determine compliance with standards. The adjusted volume is equal to the fresh food internal volume (zero for freezers) plus the freezer internal volume times an adjustment factor, which depends on the product type.
3. Based on an adjusted volume of 31 ft^3, which is the average adjusted volume for units with a rounded total refrigerated volume of 18 ft^3 per the DOE CCD.
4. Maintenance costs include cost of repairing integral components (e.g., compressor, evaporator fan electronics).

Note:
Current standard went into effect in September 2014.
ENERGY STAR V. 5.1 went into effect September 2014.
Assume same lifetime as chest freezers.

U21806-MNSC-CE-0771-Att 4

Residential Freezers

Final

Return to Table of Contents

- Current Federal standards[1]:
  - Compliance required beginning September 15, 2014
  - Models divided into 10 product classes based on size (standard or compact), orientation (chest or upright), type of defrost (automatic or manual), installation configuration (freestanding or built-in), and presence of automatic icemaker
    - Current analysis focuses on the two representative product classes analyzed in the recent rulemaking, chest and upright freezers.
  - Limits on annual electricity consumption expressed as functions of adjusted volume[2]
    - Chest freezers and all other freezers except compact freezers (PC 9): 9.88AV + 143.7
    - Upright freezers with automatic defrost (PC 10): 12.43AV + 326.1
- ENERGY STAR criteria limit annual electricity consumption to 10% less than the Federal standard
  - No ENERGY STAR compliant products at the typical capacity for chest freezers
- Energy efficiency opportunities for freezers include:
  - Higher efficiency and/or variable-speed compressor systems
  - Larger heat exchangers
  - Permanent-magnet fan motor systems (vs. shaded pole motor (SPM) and PSC fan motors)
  - Demand defrost systems
  - Vacuum-insulated panels
  - Thicker insulation (though at a loss of consumer utility)
  - Refrigerants (Isobutane vs. R134a)
  - Variable anti-sweat heating
  - Use of forced convection condenser (for upright freezers)
- Advanced Case: Increased market incentives will push product sales of upright freezers towards the ENERGY STAR level, but the technologies used to meet ENERGY STAR are already well-known and prices will likely not rise as manufacturing volumes increase at higher efficiencies. Unlikely to occur for chest freezers due to such a low existing market penetration of ENERGY STAR products.

[1]Energy Conservation Standards for Residential Refrigerators, Refrigerator-Freezers, and Freezers. 10 CFR 430.32(a).
[2]Adjusted Volume (AV) = (Fresh Volume) + 1.76 × (Freezer Volume).

	5.0	5.0	5.0	5.0	5.0	5.0	5.0	5.0	5.0	5.0
Integrated Annual Energy Consumption (kBtu/y)[1]	3,099	2,874	2,874	2,561	2,874	2,561	2,874	2,561	2,874	2,561
Average Life (y)	15	15	15	15	15	15	15	15	15	15
Retail Equipment Cost (2022$) [2]	750	770	770	850	770	850	770	850	770	850
Total Installed Cost (2022$) [2]	900	920	920	1,000	920	1,000	920	1,000	920	1,000
Annual Maintenance Cost (2022$)[3]	-	-	-	-	-	-	-	-	-	-

1. IAEC of a natural gas range is calculated as the sum of the IAEC for a natural gas cooktop and natural gas oven. IAEC of the oven component is reflective of freestanding self-clean gas ovens, which represent the majority of the market. The 2015 IAEC value of the oven component is reflective of freestanding standard gas ovens, which was previously determined to be the most representative product class.
2. Retail and installed cost are reflective of a typical unit with standard 30-inch width and 4 to 5 cooking top heating elements. Based on data from DOE rulemakings, Gordian's RSMeans Data – Building Construction Costs 2023, and distributors, total installed cost is estimated to be around $150 more than retail equipment cost.
3. Maintenance costs are negligible.

Note:
Ranges represent the span of typical values for a given parameter.
Average life is determined using a Weibull distribution characterized by the following scale (α) and shape (β) parameters: (14.56, 5.73).

Residential Natural Gas Cooktops, Ovens, and Ranges

Return to Table of Contents

- DOE analyzes cooktops and ovens separately, although they are often sold together in a single unit that combines both a cooktop and an oven into a product referred to as a range.
- Since January 1, 1990, gas cooking products with an electrical supply cord have been required to not be equipped with a constant burning pilot light. This requirement extended to gas cooking products without an electrical supply cord, as of April 9, 2012.
- DOE published a final rule in 2009[1] in which it determined that no standard for cooking efficiency would be cost-justified.
- DOE initiated a standards rulemaking in 2014 to consider amended standards for cooking products, including gas cooktops and ovens[2].
- On September 2, 2016, DOE proposed performance-based standards for gas cooktops and ovens that would take effect in 2020, if adopted.
- DOE established the new IAEC metric, in kBtu/y, to replace cooking efficiency (%).
- On December 14, 2020, DOE initially determined that amended energy conservation standards for consumer conventional cooking products would not be economically justified and would not result in significant conservation of energy[3].
- On February 2, 2023, DOE proposed new and amended energy conservation standards for consumer conventional cooking products[4].
- The IAEC of a range is calculated as the sum of the IAECs for cooktops and ovens. However, retail and installation costs for a range are similar to the cost of an oven.

DATA	2015	2020	2022		2030		2040		2050	
	Installed Base	Installed Base	Typical	High	Typical	High	Typical	High	Typical	High
Typical Capacity (W)	1,200	1,200	1,200	1,200	1,200	1,200	1,200	1,200	1,200	1,200
	3,700	3,700	3,700	3,700	3,700	3,700	3,700	3,700	3,700	3,700
Integrated Annual Energy Consumption (kWh/y)[1]	155	155	155	119	155	119	155	119	155	119
Average Life (y)	17	17	17	17	17	17	17	17	17	17
Retail Equipment Cost (2022$)[2]	470	470	470	810	470	810	470	810	470	810
Total Installed Cost (2022$)[2]	620	620	620	1,230	620	1,230	620	1,230	620	1,230
Annual Maintenance Cost (2022$)[3]	-	-	-	-	-	-	-	-	-	-

1. Although there is no performance standard in effect, the test procedure metric has changed from Cooking Efficiency (%) to IAEC (kBtu/y). IAEC was determined using DOE rulemaking data for the most representative product class, electric smooth element cooking tops, which covers cooking tops with electric resistance heating elements and cooking tops with induction heating elements.
2. Equipment and installed costs are for cooktops only (not combined range units). Costs were determined using DOE rulemaking data for the most representative product class, electric smooth cooking tops, which includes cooking tops with electric resistance heating elements and cooking tops with induction heating elements. A high-end unit with induction technology is expected to have a greater retail equipment cost and greater installation cost in order to implement this technology.
3. Maintenance costs are negligible.

Note:
The range for typical capacity represents the span of typical values.
Average life is determined using a Weibull distribution characterized by the following scale (α) and shape (β) parameters: (16.88, 6.99).

	5.0	5.0	5.0	5.0	5.0	5.0	5.0	5.0	5.0	5.0
Integrated Annual Energy Consumption (kWh/y)[1]	510	510	510	397	510	397	510	397	510	397
Average Life (y)	17	17	17	17	17	17	17	17	17	17
Retail Equipment Cost (2022$) [2]	630	630	630	900	630	900	630	900	630	900
Total Installed Cost (2022$) [2]	770	770	770	1,050	770	1,050	770	1,050	770	1,050
Annual Maintenance Cost (2022$)[3]	-	-	-	-	-	-	-	-	-	-

1. IAEC of an electric range is calculated as the sum of the IAEC for an electric cooktop and an electric oven. IAEC of the electric cooktop component was determined using DOE rulemaking data for the most representative product class, electric smooth element cooking tops, which covers cooking tops with electric resistance heating elements and cooking tops with induction heating elements. IAEC of the electric oven component was determined using DOE rulemaking data for freestanding electric self-clean ovens, which represent the majority of the market.
2. Retail and installed cost are reflective of standard units that are 30-inch wide and have 4 to 5 cooking top heating elements. Based on data from DOE rulemakings, Gordian's RSMeans Data – Building Construction Costs 2023, and distributors, total installed cost is estimated to be around $140 more than retail equipment cost for a typical unit, and $150 more than retail equipment cost for a high-end unit. A high-end unit with an induction cooking top component is expected to have a greater retail equipment cost and greater installation cost in order to implement this technology.
3. Maintenance costs are negligible.

Note:
Ranges represent the span of typical values for a given parameter.
Average life is determined using a Weibull distribution characterized by the following scale (α) and shape (β) parameters: (16.88, 6.99).

Annual Maintenance Cost (2022$)[3]	-	-	-	-	-	-	-	-	-	-	-	-

1. ENERGY STAR V. 1.1 applies to vented and ventless standard electric clothes dryers.
2. The efficiency metric changed from EF to combined energy factor (CEF) in 2015. The 2015 Installed Base CEF data accounts for units tested to appendix D1 and appendix D2, because data specific to each appendix is not available for that year.
3. Maintenance costs are negligible. DOE estimated that on average 2.7 percent of electric and 3.3 percent of gas residential clothes dryers are repaired each year. (EERE 2014)

Note:
DOE test procedures for consumer clothes dryers appear at title 10 of the Code of Federal Regulations part 430, subpart B, appendix D1 and appendix D2. The second test method, appendix D2, was finalized in a final rule published by DOE on August 14, 2013. For current standard testing, units must be tested according to either the appendix D1 or the appendix D2 test method. ENERGY STAR V. 1.1 requires certified units to be tested according to the appendix D2 test method. The appendix D1 and appendix D2 test methods determine CEF differently.
The current standard went into effect in January 2015.
ENERGY STAR V. 1.1 went into effect in May 2017.
The range for average life represents the span of typical values.

Residential Clothes Dryers

Final

Return to Table of Contents

- Current standards[1] in effect since 2015:
  - For standard-size electric units : CEF ≥ 3.73 pound per kilowatt hours (lb/kWh)
  - For gas units: CEF ≥ 2.30 lb/kWh
  - Units may be tested according to the test method in appendix D1 or appendix D2, which was finalized in 2013.
- The main differences between appendix D1 and appendix D2 are:
  - Appendix D2 includes test methods that more accurately measure the effects of automatic cycle termination and that may result in differences in the total measured energy consumption of the test cycle as compared to the test methods in appendix D1.
  - Appendix D2 contains instructions for the testing of timer dryers, which include a lower final moisture content (FMC) of the test load as compared to the version of appendix D1 used for the 2011 rulemaking analysis.
- Efficiency improvement technologies for clothes dryers include:
  - Multi-step or modulating heat
  - Higher efficiency drum motors
  - Inlet air pre-heat
  - Better control systems for cycle termination
  - Heat pump (for electric clothes dryers)
- EPA developed ENERGY STAR V. 1.1, which became effective in 2017 and requires units to be tested according to the test method in appendix D2.
- Standard-size heat pump clothes dryers with CEF values up to 11.0 are currently available in the U.S. market. High initial cost has limited market penetration, but some utilities are offering rebates to support market penetration.
- Advanced Case: Due to increases in market incentives, the residential electric clothes dryers market will see an increase in adoption of heat pump dryers that improve the typical efficiency products.

Residential Clothes Washers

Final

Return to Table of Contents

- The analysis treats front- and top-loading models separately due to their different energy use characteristics.
- Federal standards[1] for standard-capacity clothes washers (≥ 1.6 ft^3):

	Integrated Modified Energy Factor		Integrated Water Factor	
	Top-Loading	Front-Loading	Top-Loading	Front-Loading
Current DOE Standard (effective 1/1/2018)	≥ 1.57	≥ 1.84	≤ 6.5	≤ 4.7
Current ENERGY STAR V. 8.1 (effective 4/22/2021)	≥ 2.06	≥ 2.76	≤ 4.3	≤ 3.2

- In 2020, about 40% of top-loading models and almost all front-loading models achieved the ENERGY STAR level.
- Energy efficiency improvement technologies for clothes washers include:
  - Higher efficiency motors and higher spin speeds
  - Better load sensing for adaptive water fill control
  - Reduced water temperature and quantity, while providing equivalent cleaning and rinsing performance
- Maintenance costs include replacement or repair of the drain pump, control board, motor, rubber gaskets, or control panel knobs.
- The products on the market with the highest IMEF have significantly larger capacity and therefore use more energy per cycle than typical, smaller capacity products but still perform more efficiently on a per volume basis.

[1]Energy Conservation Standards for Consumer Clothes Washers. 10 CFR 430.32(g).

DATA	2015	2020	2022				2023	2030		2040		2050	
	Installed Base	Installed Base	Current Standard	Typical	ENERGY STAR V. 6.0	High	ENERGY STAR V. 7.0	Typical	High	Typical	High	Typical	High
Typical Annual Energy Use (kWh/y)	295	270	307	270	270	225	240	240	225	240	225	240	225
Water Consumption (gal/cycle)	4.25	3.50	5.00	3.50	3.50	2.40	3.20	3.20	2.40	3.20	2.40	3.20	2.40
Water Heating Energy Use (kWh/y)[1]	154	125	176	123	123	84	112	123	84	123	84	123	84
Average Life (y)	15	15	15	15	15	15	15	15	15	15	15	15	15
Retail Equipment Cost (2022$)	440	380	310	340	340	500	430	340	500	340	500	340	500
Total Installed Cost (2022$)	840	570	490	520	520	690	610	520	690	520	690	520	690
Annual Maintenance Cost (2022$)[2]	-	-	-	-	-	-		-	-	-	-	-	-

1. Refers to that portion of "Typical Annual Energy Use" that is the energy used to heat water in a separate water heater before it enters the dishwasher. The energy used to heat water inside the dishwasher cannot be disaggregated from the total.
2. Maintenance costs are negligible.

Note:
All values in table reflect 215 cycles/year according to the current test procedure at 10 CFR 430 Appendix C1.
The current standard went into effect in May 2013.
ENERGY STAR V. 6.0 went into effect in January 2016.
ENERGY STAR V. 7.0 will go into effect in July 2023.
Average life is determined using a Weibull distribution characterized by the following scale (α), shape (β), and delay (θ) parameters: (15.9, 1.8, 1).

Residential Dishwashers

- Performance criteria for standard-capacity dishwashers (assumes 215 cycles/year):
  - Federal Standards:
    - May 30, 2013: ≤ 307 kWh/y, ≤ 5.0 gal/cycle (DOE Direct Final Rule, published May 2012)
  - ENERGY STAR Criteria:
    - Jan. 29, 2016: ≤ 270 kWh/y (5% allowance for connected), ≤ 3.5 gal/cycle (V. 6.0)
    - July 19, 2023: ≤ 240 kWh/y, ≤ 3.2 gal/cycle (V. 7.0, effective August 2023)
- ENERGY STAR has maintained a very high market share for several years (93% in 2021), so sales-weighted average efficiency has tracked ENERGY STAR levels.
  - Due to the historically high market penetration of ENERGY STAR products, it is expected that manufacturers will make the necessary adjustments so ENERGY STAR V. 7.0 levels will be typical in future projections.
- Test procedures:
  - Accounts for motor, dryer, booster heater (if present), and hot water from separate water heater, as well as standby and off-mode energy.
  - ENERGY STAR established a cleaning performance test method. While cleaning performance reporting is currently optional, V. 7.0 requires a cleaning index of 65 or higher for ENERGY STAR certification.
  - In January 2023, DOE established a test procedure at Appendix C2, which would go into effect at the time of any amended energy conservation standards. Appendix C2 establishes a minimum cleaning index threshold of 70 as a condition for a valid test cycle. The cleaning index threshold of 70 established by DOE is equivalent to the cleaning index threshold of 65 specified in ENERGY STAR V. 7.0.
- Efficiency improvement technologies for dishwashers include:
  - Better soil sensing
  - Control strategies
  - Water distribution (small pipes, fine filter, small sump, multiple spray arms, alternating water use) and controls (flow meter, temperature sensor)
  - Inline water heater (to minimize sump volume)
  - Separate drain pump, high-efficiency, variable-speed circulation pump motor
  - Condensation drying (rather than power dry)

1. In 2023, the new Energy Conservation Standards for Commercial Warm Air Furnaces (CWAF) took effect. These projections reflect the 2023 minimum thermal efficiency requirement for gas-fired furnaces, 81%.
2. When this analysis was previously conducted in EIA Technology Forecast Updates (2018), a typical input capacity of 400 kBtu/h was listed. An updated typical input capacity value of 250 kBtu/h was determined through an evaluation of the units in the DOE CCD as of August 2022. CWAF EERE 2015 also listed a representative input capacity of 250 kBtu/h.
3. DOE's efficiency metric for commercial furnaces accounts only for flue losses, not jacket losses.

Note:
The previous standard went into effect in January 1994. The current standard went into effect in January 2023.

U21806-MNSC-CE-0771-Att 4

Commercial Gas-Fired Furnaces

Final

Return to Table of Contents

- Until 2022, the Federal standard required minimum 80% thermal efficiency. This metric, more commonly called "combustion efficiency" in other contexts, accounts only for flue losses, not jacket losses.
  - The Federal standard applied to all units manufactured on or after January 1, 1994, with maximum rated heat input ≥ 225,000 Btu per hour.
  - On January 1, 2023, the minimum Federal standard increased to 81% thermal efficiency.
- ASHRAE Standard 90.1, which is used as a commercial building code in many states, stipulates that furnaces that are not within the conditioned space shall not have jacket losses exceeding 0.75% of the input rating.
- Commercial furnaces are typically non-condensing with thermal efficiencies ranging from 80% to 81%. Condensing commercial furnaces, which can achieve up to 95% thermal efficiency, were previously introduced to the market but are not currently available due to cost and reliability concerns. The highest thermal efficiency included in DOE's CCD at this time is 81%.
- Besides capacity, commercial units can differ from residential furnaces in terms of the control system (i.e., integration with a Building Management System, twinning, or other staging strategies). Commercial systems may also use a heat recovery system to pre-heat inlet air.
- Advanced Case: Increased high efficiencies are feasible due to market incentives to re-introduce condensing commercial gas-fired furnaces through additional investment, research, and development. No significant changes otherwise.

Annual Maintenance Cost (2022$/kBtu/h)	-	-	-	-	-	-

1. Capacity is output.
2. Retail and installed costs for 2022 and forecasts for 2030 and beyond are based on Gordian's RSMeans Data – Building Construction Costs 2023. Maintenance costs are same as EIA Technology Forecast Updates (2018), updated to reflect 2022$. The costs shown are for one 165kW unit, which would equate to a steady load of approximately 550,000 Btu/h. Annual maintenance in a typical application would include draining the unit for removal of any accumulated scale or sludge buildup.

U21806-MNSC-CE-0771-Att 4

Commercial Electric Boilers

Final

Return to Table of Contents

- There are currently no federal standards associated with electric boilers.
- The costs shown are for one 165kW unit, which would equate to a steady load of approximately 550,000 Btu/h.
- Service life is determined mainly by water quality. Water conditioning (e.g., filters, softeners, de-alkalizers, chemical feeders) may be necessary for a given application.
- Annual maintenance in a typical application would include draining the unit for removal of any accumulated scale or sludge buildup.
- Minor end-use inefficiencies for electric boilers result from heat loss through the boiler (jacket losses).

1. The standard level shown here is for small (300 kBtu/h to 2500 kBtu/h) gas-fired hot water commercial packaged boilers, which are the most common type of boilers available on the market.
2. DOE's efficiency metric for most boiler types accounts for both flue and jacket losses; previously it did not. DOE continues to uses a combustion efficiency metric instead, for hot water boilers with heat input > 2,500,000 Btu/h.
3. Maintenance costs for 2018 and post-2018 are based on Commercial Packaged Boilers EERE 2020. The annualized maintenance costs estimated in the final rule differ for condensing vs. non-condensing boilers. Appendix 8E of the Commercial Packaged Boilers EERE 2020 TSD provides additional information on how the values are calculated.

Note:
The previous standard went into effect in March 2012.
The current standard went into effect in January 2023.
In December 2016, DOE issued a final rule titled Energy Conservation Program: Energy Conservation Standards for Commercial Packaged Boilers. This rule published in January 2020 with an effective date for January 2023.

U21806-MNSC-CE-0771-Att 4

Commercial Gas-Fired Boilers

Final

Return to Table of Contents

- Commercial packaged gas-fired boilers are classified by:
  - Heat input capacity
  - Produce steam or hot water
  - Draft type (natural draft or not) – for steam boilers
- The most common type of commercial gas-fired boilers are small gas-fired hot water boilers with 300,000-2,500,000 Btu/h rated heat input.
- Similar technologies to those used in the residential gas-fired boilers market can be leveraged in the commercial arena. The higher efficiency units typically include electronic ignition, power burners, and improved heat exchangers. Some gas-fired boilers also condense water vapor from the flue gases to improve heating efficiency.
- DOE published a final rule for commercial packaged boilers in January 2020 that updated the efficiency ratings of gas-fired commercial packaged boilers beginning January 2023.
- Advanced Case: Condensing gas-fired boilers are expected to dominate the market by 2030, with corresponding price increases.

Annual Maintenance Cost (2022$/kBtu/h)	3	3	3	3	3	3	3	3	3	3	3

1. Capacity is output.
2. ASHRAE 90.1 data are for units larger than 400 tons and for full-load optimized applications (Path A in ASHRAE 90.1-2019). Typical and high efficiency levels are determined based on the range of products currently available on the market.

Note:

For most chillers (including those in single-chiller applications and for peaking units in multi-chiller applications), the seasonal performance (represented by the integrated part-load value (IPLV)) is more indicative of annual expected performance than the full-load performance; performance of baseload chillers in multi-chiller applications, which typically operate at full-load, are well represented by the full-load efficiency value.

ASHRAE 90.1 went into effect in October 2019.

Ranges represent the span of typical values for a given parameter.

U21806-MNSC-CE-0771-Att 4

Commercial Centrifugal Chillers (Water-Cooled)

Final

Return to Table of Contents

- ASHRAE 90.1-2019 stipulates minimum efficiencies for centrifugal chillers separately from positive displacement water-cooled chillers. They are separated into 5 size categories, with categories divided at: 150, 300, 400, and 600 tons; ASHRAE 90.1-2019 also distinguishes between whether the unit will be optimized for full-load (Path A) or part-load operation (Path B). Data here are for Path A; a Path B chiller may have slightly high full-load consumption in exchange for much lower part-load consumption. For example, for a 600-ton unit:
  - Path A: ≥ 0.56 kW/ton full-load and ≥ 0.50 kW/ton IPLV
  - Path B: ≥ 0.585 kW/ton full-load and ≥ 38 kW/ton IPLV
- Federal Energy Management Program (FEMP) recommendations, last updated in 2020, match ASHRAE 90.1-2019.
- The highest efficiency centrifugal chillers incorporate some of the following:
  - Variable speed drive (VSD) compressors
  - Dedicated heat recovery (heat pump chiller)
  - Magnetic bearing technology (oil-free operation)
  - Greater heat exchanger surface areas; enhanced tube configurations (counterflow)
  - Optimized fluid flow velocities
  - High efficiency electric motors
  - Improved turbomachinery design, resulting in higher compressor efficiency
  - Better piping and valving, including electronic expansion valves
  - Evaporative condenser for the heat rejection equipment
- Installed costs vary widely depending on equipment needed for installation (e.g., crane) and size of system. This is a mature market with centrifugal chillers representing 75% of commercial chiller sales larger than 200 tons.
- Water-cooled chiller ratings do not include energy consumption of the cooling tower and therefore are not directly comparable to rating for air-cooled chillers. Water-cooled centrifugal chillers were selected for analysis due to a higher model share on the AHRI directory in comparison to air-cooled chillers.
- Advanced Case: Due to increases in R&D, improvements in current technology are expected to increase efficiency without substantially increasing costs.

Commercial Reciprocating Chillers (Air-Cooled Only)

Final

Return to Table of Contents

- Reciprocating chillers are most cost effective for small loads (30 to 150-ton range). However, reciprocating chiller market share continues to be supplanted by screw and scroll chillers. This trend has accelerated with the phase out of R-22, which was the refrigerant of choice for reciprocating products, which has in turn driven major manufacturers to replace their reciprocating product lines with scroll products (rather than redesign reciprocating products for new refrigerants). As a result, product options are very limited.
- Reciprocating chillers can be used in either air-cooled or water-cooled applications. Reciprocating chillers shown in the data are air-cooled. Air-cooled chillers are less efficient than the water-cooled models. Listed efficiencies include matched condensers and their associated energy use.
- ASHRAE 90.1-2019 stipulates minimum efficiencies for all air-cooled chillers together, including reciprocating chillers, while water-cooled chillers are separated by positive displacement (e.g., reciprocating) versus centrifugal models. Air-cooled chiller efficiencies are further split by size for more and less than 150 tons. ASHRAE 90.1-2019 also distinguishes between whether the unit will be optimized for full-load (Path A) or part-load operation (Path B). Data here are for Path A; a Path B chiller may have slightly lower full-load efficiency in exchange for much higher part-load efficiency. For example, for a 100-ton unit:
  - Path A: ≥ 10.1 EER full-load and ≥ 13.7 IPLV EER
  - Path B: ≥ 9.7 EER full-load and ≥ 15.8 IPLV EER
- FEMP (2022) recommendations for air-cooled chillers are:
  - Path A (<150 tons): ≥ 10.89 EER full-load and ≥ 13.7 IPLV EER
  - Path B (<150 tons): ≥ 9.7 EER full-load and ≥ 16.86 IPLV EER (same as 90.1-2019)
- The highest efficiency reciprocating chillers incorporate some of the following:
  - Multiple compressors for staged capacity control
  - Improved heat-exchangers

Commercial Screw Chillers (Air-Cooled Only)

Final

Return to Table of Contents

- Screw chillers are common in 150 to 500-ton capacities but are most cost effective for small (<300 tons) loads; screw chillers dominate the current market for small to mid-size chillers.
- Screw chillers can be used in either air-cooled or water-cooled applications. Screw chillers shown in the data are air-cooled. Air-cooled chillers are less efficient than the water-cooled models. Listed efficiencies include matched condensers and their associated energy use.
- ASHRAE 90.1-2019 stipulates minimum efficiencies for all air-cooled chillers together, including screw chillers, while water-cooled chillers are separated by positive displacement (e.g., screw) versus centrifugal models. Air-cooled chiller efficiencies are further split by size for more and less than 150 tons. ASHRAE 90.1-2019 also distinguishes between whether the unit will be optimized for full-load (Path A) or part-load operation (Path B). Data here are for Path A; a Path B chiller may have slightly lower full-load efficiency in exchange for much higher part-load efficiency. For example, for a ≥ 150-ton unit:
  - Path A: ≥ 10.1 EER full-load and ≥ 14.0 IPLV EER
  - Path B: ≥ 9.7 EER full-load and ≥ 16.1 IPLV EER
- FEMP recommendations for air-cooled chillers (updated June 2020) are:
  - Path A (≥ 150 tons): ≥ 10.7 EER full-load and ≥ 14.0 IPLV EER
  - Path B (≥ 150 tons): ≥ 9.7 EER full-load and ≥ 16.4 IPLV EER
- The highest efficiency screw chillers incorporate some of the following:
  - Variable speed compressors and/or multiple compressors
  - Economizers
  - Improved heat-exchangers
- Advanced Case: Due to increases in R&D, improvements in current technology are expected to increase efficiency without substantially increasing costs.

Commercial Scroll Chillers (Air-Cooled Only)

Final

Return to Table of Contents

- Scroll chillers range in size from ~20 tons to ~200 tons and can be used in either air-cooled or water-cooled applications. They are the most common type of chiller for small chiller plants. The scroll chillers shown in the data are air-cooled, which is most common. Air-cooled chillers are less efficient than the water-cooled models. Listed efficiencies include matched condensers and their associated energy use.
- ASHRAE 90.1-2019 stipulates minimum efficiencies for all air-cooled chillers together, including scroll chillers, while water-cooled chillers are separated by positive displacement (e.g., scroll) versus centrifugal models. Air-cooled chiller efficiencies are distinct for more and less than 150 tons. ASHRAE 90.1-2019 also distinguishes between whether the unit will be optimized for full-load (Path A) or part-load operation (Path B). Data here are for Path A; a Path B chiller may have slightly lower full-load efficiency in exchange for much higher part-load efficiency. For example, for a 100-ton unit:
  - Path A: ≥ 10.1 EER full-load and ≥ 13.7 IPLV EER
  - Path B: ≥ 9.7 EER full-load and ≥ 15.8 IPLV EER
- FEMP recommendations for air-cooled chillers (updated June 2020) are:
  - Path A (< 150 tons): ≥ 10.7 EER full-load and ≥ 13.7 IPLV EER
  - Path B (< 150 tons): ≥ 9.7 EER full-load and ≥ 15.9 IPLV EER
- The highest efficiency scroll chillers incorporate some of the following:
  - Multiple compressors for staged capacity control
  - Improved heat-exchangers
  - Variable speed compressor (or other modulation controls)
- With the phase out of R-22, manufacturers have replaced many of their small reciprocating chiller products with equivalent scroll products, making them a primary choice for small tonnage applications.
- Advanced Case: Due to increases in R&D, improvements in current technology are expected to increase efficiency without substantially increasing costs.

Commercial Gas-Fired Chillers (Water-Cooled, Direct-Fired Only)

Return to Table of Contents

- Gas-fired chillers are available as either air-cooled (~25-50 tons) or water-cooled (150+ tons). This analysis covers only water-cooled chillers of two varieties: absorption and engine-driven vapor compression (direct-fired only; indirect steam or hot water driven units are excluded).
- Direct gas firing provides high enough temperatures to operate double effect absorption chillers, which operate at a 50-60% higher COP than single effect systems. Triple effect chillers, though not commercially available, can boost cooling COP 30-50% beyond double effect chillers. Some companies have worked on prototype direct-fired triple effect absorption chillers, but prohibitively high cost of advanced high heat/corrosion-resistant materials required for triple effect absorption chillers suggests that this technology will not likely have an impact on the market in the near-term.
- Gas-fired engine-driven chillers pair conventional vapor compression systems (typically screw or centrifugal compressors) with natural gas powered-reciprocating engines. They exhibit higher peak cooling COP than absorbers, and engine modulation results in better part-load performance. Future efficiency improvements for engine-driven chillers are not anticipated. Engine-driven chillers allow the opportunity to recover waste heat for useful purposes.
- Maintenance costs for engine-driven chillers are higher than for other chillers because they include all the typical components of a vapor compression chiller in addition to an engine; the engine maintenance costs vary depending on the annual run hours of the unit.
- Limited sales data suggest that the U.S. market for gas-fired chillers is very limited and is mostly for replacement units, not for new installations. Recent increases in electric chiller efficiency have narrowed the operating cost differential with gas chillers. Asia has the majority of the global gas-fired chiller market.
- Gas-fired chiller installations are particularly valuable in locations where electric rates are high and gas prices are low (i.e., low spark spread), where digester or landfill gas sources are available, or where waste heat sources are available (e.g., an industrial process or microturbine CHP system) that could be used with a hybrid direct/indirect-fired absorption chiller to offset the use of natural gas.

Annual Maintenance Cost (2022$/kBtu/h)	4	4	4	4	4	4	4	4	4	4	4	4	4	4	4	4

1. Values shown are for air-cooled small commercial packaged air conditioners with either electric resistance heating or no heating within the same enclosure. DOE published a direct final rule for commercial packaged air conditioners and heat pumps in January 2016 with initial standards becoming effective in 2018 and additional standards becoming effective in 2023. As part of this rulemaking, DOE changed the regulated metric from EER to integrated energy efficiency ratio (IEER).
2. DOE investigated the relationship between IEER and EER. Because the relationship between IEER and EER is weak, this analysis estimates EER values based on the average of the values seen at a given IEER.
3. Examples of annual maintenance services include, check tensions, condition, and alignment of belts and adjust as necessary; lubricate shaft and motor bearings; replace air filters; clean coils, drain pan and piping, blowers, fan motors as required; check refrigerant pressure and compressor oil level; etc.
4. The 2022 typical efficiency is based on the average IEER from DOE's CCD. The 2022 high efficiency is based on the most-efficient model in DOE's CCD, but costs are estimated based on the most efficient unit analyzed in CUAC EERE 2016, which had an IEER of 21.5.

Note:
EER is the ratio of the cooling capacity (in Btu/h) to the power input (in watts) and provides a measure of the efficiency of equipment operating at full load (i.e., 100 percent cooling capacity) in high-ambient-temperature conditions (i.e., 95 °F). IEER is a single number part-load efficiency based on weighting of EER at various load capacities. Efficiency Conversion is the conversion of IEER from a [(Btu/h)/W] metric to a metric in the same units.
The previous standard went into effect in January 2018. The current standard went into effect in January 2023.
ENERGY STAR V. 3.1 went into effect in January 2018. ENERGY STAR V. 4.0 went into effect in January 2023.

Same as Reference Case

DATA	2012[1]	2018	2022	2030	2040	2050
	Installed Base	Installed Base	Typical	Typical	Typical	Typical
Typical Capacity (tons)	18	11	11	11	11	11
Heating COP	1.4	1.4	1.4	1.4	1.4	1.4
Cooling COP	0.9	1.2	1.2	1.2	1.2	1.2
Average Life (y)	15	15	15	15	15	15
Retail Equipment Cost ($/ton)	3,350	2,820	3,710	3,710	3,710	3,710
Total Installed Cost ($/ton)	3,820	3,290	4,110	4,110	4,110	4,110
Total Installed Cost ($/kBtu/h)	318	274	343	343	343	343
Annual Maintenance Cost (2022$)	70	70	70	70	70	70
Annual Maintenance Cost (2022$/kBtu/h)	6	6	6	6	6	6

1. The 2012 typical capacity and cooling COP were estimated as a simple average between obsolete pre-2003 units and 2013 units, which first became available in 2010; this assumes that each vintage represents about half of the installed base.

Note:
Only one product was available in 2012; the market has grown slightly in years since. Typical capacity and COP for 2018 and later are averages of units available as of 2017.

U21806-MNSC-CE-0771-Att 4

Commercial Gas-Fired Engine-Drive Rooftop Air Conditioners

Final

Return to Table of Contents

- There are only a few gas-fired engine-driven rooftop units currently available in the U.S. market. The first unit was introduced in 2010. It is an 11-ton packaged heat pump with dual scroll compressors, variable refrigerant flow, and a variable speed supply fan. Engine coolant heat recovery improves the heating mode COP.
- There are currently no Federal requirements on gas-fired engine-driven rooftop air conditioners or heat pumps.
- Annual sales of the engine-driven rooftop heat pump are estimated at less than 5,000 units per year.

1. COP values listed are assessed at a "ground loop" test condition, which is representative of closed loop GSHP operating conditions. However, DOE sets standards at a "water loop" test condition. The AHRI directory lists COP ratings at both sets of test conditions and is used to convert between them where necessary.
2. EER values listed are assessed at a full-load "ground loop" test condition, which is representative of closed loop GSHP operating conditions. However, DOE sets standards at a full-load "water loop" test condition. The AHRI directory lists EER ratings at all sets of test conditions and is used to convert between them where necessary.

Note:
Residential and commercial GSHPs are very similar - the main difference in data presented is the different capacity (3-ton vs. 4-ton) and slightly higher installation costs for commercial GSHP. DOE does not distinguish between residential and commercial units in its regulations.

U21806-MNSC-CE-0771-Att 4

Final

Commercial Ground-Source Heat Pumps

Return to Table of Contents

- The most common commercial ground-source heat pump systems are closed-loop in which water or anti-freeze solution is circulated through plastic pipes buried underground. Commercial water-to-air heat pumps (WAHPs) range in size from 1 ton or less to over 500 tons depending on whether a distributed or centralized architecture is used. Distributed systems are more prevalent.
- Most geothermal WAHPs are rated for capacity and efficiency based on the ISO 13256-1 standard. Heating and cooling efficiency measurements under this standard include input energy for fans and pumps on a proportional basis that only includes that power required to transport air and liquid through the heat pump. The reason for this method is to simplify comparisons between heat pumps and to allow equipment to be optimized for real world conditions without suffering rating penalties. Real world energy use will exceed ratings predictions as a result of higher fluid static pressure requirements.
- ISO 13256-1 cooling rating conditions require 77 °F entering water temperature and 80.6 °F entering air temperature. More typical peak design criteria would be 80-90 °F entering water temperature and 75 °F entering air temperature. As a result, ISO 13256-1 rated cooling efficiency would be higher than typical design peak operation.
- Some WAHPs include efficiency data for a part-load operating condition as allowed by ISO 13256-1 for multiple stage or variable speed compressors. No seasonal energy efficiency metric (analogous to SEER or IEER) currently applies to WAHPs. The annual performance of a geothermal WAHP system can vary more widely than for other system types due to the large influence of ground loop design and characteristics.
- The ENERGY STAR criteria for ground-source heat pumps apply only to residential applications.
- Installation cost is for a closed loop system and includes necessary accessories. The ground loop heat exchanger and distribution pumping systems represent a majority of the installation cost.
- Low end WAHPs utilize single stage compressors. Higher efficiency units incorporate multiple stage or variable speed compressor controls to improve efficiency as well as humidity and temperature control. Variable speed ECM fan motors also improve overall energy efficiency.
- Advanced Case: Ground-source heat pumps are already highly efficient and have not changed much in terms of efficiency in recent years. With increased R&D, it is anticipated that the equipment and installation costs will be reduced over time, but efficiency will likely stay the same.

Commercial Gas-Fired Storage Water Heaters

Final

Return to Table of Contents

- Input capacity > 155 kBtu/h and storage capacity ≤ 140 gal
- Federal standard:
  - Minimum thermal efficiency: 80%
  - Maximum standby loss (Btu/h) : Input Rate/800 + 110 × (Rated Volume)$^{1/2}$
- ENERGY STAR requirements:
  - Minimum thermal efficiency: 94%
  - Maximum standby loss (Btu/h): 0.84 × [(Input Rate/800) + 110 × (Rated Volume)$^{1/2}$]
- Baseline units are typically constructed similarly to residential units, though with higher input capacities (and often higher storage volumes).
- High-efficiency units include condensing heat exchangers (typically stainless or enameled steel) to extract additional heat by condensing water vapor in flue gases. Condensing units also include an inducer fan system or power burner. The heat exchanger is typically contained within the tank, but some designs consist of an external heating module attached to a storage tank. Condensing units are expected to be the majority market share by 2030.
- Maintenance consists of sediment and scale removal once or twice per year and replacement of miscellaneous components such as gaskets and sealants. Condensing units have an additional cost for replacement of condensate neutralizer media every two years.

Commercial Electric Resistance Storage Water Heaters

Final

Return to Table of Contents

- Federal standard:
  - Maximum standby loss (%/h) : 0.30 + 27/Measured Storage Volume
  - Minimum thermal efficiency: no standard, but all units have an efficiency ≥ 98%
- Storage capacity: typically, 50 to 120 gallons, though smaller and larger units exist for specialized applications
- Commercial units are typically constructed similar to residential units, though with higher input capacities (and often higher storage volumes).
- There is very little variation in thermal efficiency on the market; variation in standby loss is typically due to tank design and insulation thickness.
- Maintenance consists of sediment and scale removal once or twice per year.

U21806-MNSC-CE-0771-Att 4

Commercial Electric Resistance Storage Water Heaters

Final

Return to Table of Contents

Annual shipments increased by almost 50% between 2002 and 2008. After a small dip in shipments in 2009, annual shipments have increased by about 173% between 2009 and 2017, stabilizing between 140-150 thousand shipments per year since then.

1. Water flow rate scales with typical capacity. The storage tanks must be purchased and installed separately from the HP unit. The typical output and flow rate provided are near the median of the products available on the market currently.
2. Costs are same as EIA Technology Forecast Updates (2018), updated to 2022$. Updated representative costs for commercial heat pump water heaters are not available due to the extremely small market for these products.

Note:
ENERGY STAR V. 2.0 went into effect in October 2018.

U21806-MNSC-CE-0771-Att 4

Commercial Heat Pump Water Heaters

Final

Return to Table of Contents

- Typical commercial HPWHs (CHPWHs) are add-on units designed to be used with a storage tank(s); integrated CHPWHs have emerged on the market (i.e., heat pump module and storage tank combined in one unit) in recent years.
- CHPWHs serve only a small portion of the commercial water heating (CWH) market, with the ENERGY STAR database listing only two manufacturers, each with one basic model listed.
- CHPWHs can extract heat from either air or water for heating potable water ("air-source" or "water-source"). The capacity of air-source CHPWHs falls at lower ambient air temperatures.
- Air-source CHPWHs cool the surrounding air, which can be desirable when installed indoors in applications with a year-round cooling load (e.g., a commercial kitchen).
- Output capacities for CHPWHs range from 17 kW to over 70 kW for air-source units and over 600 kW for water-source units.
- Some commercial applications require water as hot as 180 °F, such as dishwashing; however, most CHPWHs cannot deliver hot water at temperatures higher than 150 °F.
- There are no current Federal standards for CHPWHs, but DOE prescribes a test procedure for determining COP_h for CHPWHs.
- The most recent ENERGY STAR V. 2.0 specification for CWH equipment went into effect in October 2018. It specifies a COP_h level of 3.0 for CHPWHs.
- Advanced Case: Due to increases in R&D, improvements in current technology (e.g., more cost-effective variable speed technology) are expected to increase efficiency without substantially increasing costs.

1. While EIA Technology Forecast Updates (2018) included high values reflecting condensing models, models currently available in the market do not exceed 80% efficiency.
2. The 2012 and 2018 installed base costs are the same as EIA Technology Forecast Updates (2018), updated to 2022$. Retail costs for 2022 and later are based on the range of costs for products on the market today. Installed costs assume a $300 installation price.

U21806-MNSC-CE-0771-Att 4

Commercial Booster Water Heaters

Final

Return to Table of Contents

- Booster water heaters are installed, often at the point of use, in series with the main service water heating system to boost service water temperatures. The main service water heating system may provide 110-140 °F water, and the booster water heater may increase that temperature to 180-195 °F. Typical commercial applications for booster water heaters include commercial dishwashers, laundromats, hospitals, and car washes.
- Commercial booster water heaters are regulated by DOE as either storage or instantaneous water heaters, depending on the ratio of input capacity to storage volume. Units with input capacity < 4,000 Btu/h per gallon of stored water are storage water heaters; all other units are instantaneous water heaters.
- DOE's regulations do not currently include standards for electric instantaneous water heaters, but standards are included for electric storage water heaters, gas-fired instantaneous water heaters, and gas-fired storage water heaters.
- Condensing gas-fired booster water heaters, those with an efficiency of 90% of more, were analyzed previously. There are no condensing units currently on the market. Condensing gas-fired booster water heaters can only operate if the incoming water temperature is below 130 °F so there is enough heat transfer to condense.
- Booster water heaters typically have short lifetimes because of high usage and extreme temperatures.
- Shipments are small due to the limited number of applications.
- Advanced Case: increased high efficiencies are possible due to market incentives to re-introduce condensing commercial gas-fired booster water heaters through additional investment, research, and development. No significant changes otherwise.

1. Commercial gas-fired instantaneous water heaters are categorized into two groups: tankless water heater and hot water supply boiler. Tankless units are similar in design to residential tankless units. The hot water supply boiler has a much higher input and is similar in design to boilers. The large variation of total input capacity and design causes a large range of costs. The range of retail, installed, and maintenance costs represent the differences in design, as well as the cost ranges arising from replacement versus new construction markets.
2. High efficiency was determined based on DOE's CCD. The most efficient tankless water heater has a thermal efficiency of 96%. The most efficient hot water supply boiler has a thermal efficiency of 99%.
3. Maintenance consists replacement of miscellaneous components such as gaskets and sealants. Condensing units have an additional cost for replacement of condensate neutralizer media every two years.

Note:
For the installed base, current standard, and typical costs, low values represent costs for tankless water heaters in the replacement market while high values represent costs for hot water supply boilers in the new construction market. The range of costs for the High values are estimated costs for hot water supply boilers in the replacement and new construction market.
ENERGY STAR V. 2.0 went into effect in October 2018.

U21806-MNSC-CE-0771-Att 4

Commercial Gas-Fired Instantaneous Water Heaters

Final

Return to Table of Contents

- Storage Capacity < 10 gallons and ≥ 10 gallons
- Federal standard:
  - Minimum thermal efficiency: 80%
  - Maximum standby loss (Btu/h): Input Rate/800 + 110 x (Rated Volume)$^{1/2}$
- ENERGY STAR requirements:
  - Minimum thermal efficiency: 94%
- Wall-mounted ("tankless") units typically do not exceed ~400,000 Btu/h and are similar in design to residential tankless units. Floor-mounted units ("circulating" or "volume" water heaters) are similar in design to boilers and can have input capacities in the millions of Btu/h. Floor-mounted units are typically installed with a storage tank.
- Despite high available input capacities, some installations use multiple units staged together, which may have reliability and/or efficiency benefits.
- Similar to storage water heaters, higher efficiencies are achieved with condensing operation, which requires a condensing heat exchanger and inducer fan or power burner. Some units include both non-condensing and condensing heat exchangers, while others include a single condensing heat exchanger.
- When replacing a storage water heater with an instantaneous water heater, there may be significant additional costs to upsize the gas supply line and change the venting.

U21806-MNSC-CE-0771-Att 4

Commercial Gas-Fired Instantaneous Water Heaters

Final

Return to Table of Contents

Annual shipments for gas-fired instantaneous tankless water heaters have gradually increased since 2000 while those for gas-fired instantaneous hot water supply boiler water heaters peaked in 2008 and have been decreasing since then, recently stabilizing around 10,000 annual shipments.

1. Typical capacity refers to the solar collector panel area. It was determined using the SRCC database as the average value of the largest bin (in terms of capacity) with the greatest number of units.
2. In 2020, the efficiency metric for solar water heaters changed from SEF to SUEF. There is no equation or scaling factor readily available to translate SEF to SUEF. Accordingly, for the 2012 and 2018 installed base, SUEF was determined using the 2020 ENERGY STAR data set assuming the typical SEF/SUEF value was similar between 2012-2020. For 2022 and beyond, due to lack of SUEF data, it is assumed that a typical electric backup unit would meet the ENERGY STAR criteria. ENERGY STAR specifies a minimum SUEF of 3.0 for electric backup units and 1.8 for gas backup units.
3. Costs are for an indirect (active closed loop) system, including tank and backup heater. Smaller capacity/cost systems are typical for southern & western states (>two-third of the current market). Higher capacity/cost systems are required in colder/cloudier regions. The 2012 and 2018 installed base costs are updated from EIA Technology Forecast Updates (2018) to 2022$.
4. Annual maintenance is expected to be 0.5% to 1% of the total installation.

Note:
ENERGY STAR V. 4.0 went into effect in January 2022. ENERGY STAR V. 5.0 will go into effect in April 2023 but the ENERGY STAR criteria for solar water heaters will remain the same in ENERGY STAR V. 5.0.

U21806-MNSC-CE-0771-Att 4

Commercial Solar Water Heaters

Final

Return to Table of Contents

- In 2020, a diverse group of stakeholders from the solar thermal industry developed the SUEF Specification for solar water heaters. The goal of this specification is to align with the UEF metric used by DOE for other water heating technologies.
- SUEF is also the metric used by the current ENERGY STAR Specification, and it replaced the SEF metric.
- EIA Technology Forecast Updates (2018) presented results using SEF and solar fraction (SF). SEF is currently not used in either the ENERGY STAR or SRCC databases; accordingly, this report presents results according to SUEF. SF is the portion of the total conventional hot water heating load (delivered energy and tank standby losses). SF varies from 0 to 1.0. Typical solar fraction values are 0.5–0.75.
- There is no equation or scaling factor readily available to translate SEF to SUEF. Accordingly, for the 2012 and 2018 installed base, SUEF was determined using the 2020 ENERGY STAR data set assuming the typical SEF/SUEF value was similar between 2012-2020. For 2022 and beyond, SUEF is the average SUEF for solar water heaters with a "high-usage" draw pattern from the current ENERGY STAR qualified product list.
- Commercial solar water heaters are typically custom designed for a specific installation.
- Commercial solar water heaters may include backup heating, from sources such as electric resistance or hydronic heat (supplied from a gas-fired boiler or geothermal heat pump).
- Storage volumes of tanks for commercial solar water heaters can span from 140 gallons to over 2,000 gallons.
- SRCC's OG-300 can be used to certify commercial systems, but most commercial systems are larger and unique; this certification program is mostly used for residential solar water heaters.
  - Many incentive programs require that solar collectors for commercial systems be certified to SRCC's certification program for collectors, OG-100.

1. ENERGY STAR does not cover combination products that include griddles, ranges, and ovens in one single package. The ENERGY STAR levels provided here reflect specifications for individual products. Range tops are not covered by ENERGY STAR.
2. ENERGY STAR V. 3.0 updated the requirements for commercial ovens from V. 2.2, effective January 2023. Data shown is reflective of a standard full-size convection oven that holds 5 or more pans.
3. Combined energy efficiency and combined idle energy rate are calculated as a weighted average of each component using typical daily operating hours sourced from Food Service Technology Center (FSTC). Typical daily operating hours are assumed to be 12 hours for the griddle component, 8 hours for the oven component, and 12 hours for the range component.
4. Products in the commercial cooking market generally do not scale in price with relation to cooking efficiency. Distributors also do not provide this information.
5. Maintenance costs are negligible.

Note:
ENERGY STAR V. 2.2 went into effect in October 2015. ENERGY STAR V. 3.0 went into effect in January 2023.

Commercial Ranges with Griddle and Oven

Final

Return to Table of Contents

- Combined product that typically includes 2-6 range tops, a 24 in. x 24 in. griddle surface, and one or two half- or full-size ovens.
- Combined product is not covered by ENERGY STAR. However, the individual product ENERGY STAR V. 2.2 specifications are provided below.

Product	ENERGY STAR V. 2.2 Requirements	Gas	Electric
Griddle	Cooking Energy Efficiency	≥ 38%	≥ 70%
	Normalized Idle Energy Rate	≤ 2,650 Btu/h per ft^2	≤ 0.320 kW per ft^2
Oven	Cooking Energy Efficiency	≥ 46%	≥ 71%
	Idle Energy Rate	≤ 12,000 Btu/h	Half size: ≤1.00 kW Full size: ≤1.60 kW

- ENERGY STAR does not provide certification for range tops.
- There are no Federal standards for commercial cooking products.
- Product pricing in this market do not scale with efficiency, but rather depend on a number of other factors such as brand name, aesthetics, and additional features.

U21806-MNSC-CE-0771-Att 4

Commercial Ranges with Griddle and Oven

Final

Return to Table of Contents

- ENERGY STAR V. 3.0 requirements for commercial ovens went into effect in January 2023:

Product	ENERGY STAR Requirements	Gas	Electric
Oven	Cooking Energy Efficiency	≥ 49%	Half size: ≥ 71% Full size: ≥ 76%
	Idle Energy Rate	≤ 9,500 Btu/h	Half size: ≤1.00 kW Full size ≥ 5 Pans: ≤1.40 kW Full size ≤ 5 Pans: ≤1.00 kW

- Advanced Case: Increased market incentives are expected to drive efficiency improvements. However, because cost does not scale with efficiency, there is no significant expected change in cost.

1. Interior volume is characterized by the product size classes reported by ENERGY STAR. The small size class covers units with interior volume less than 13 ft^3. Interior volume for the small size class was determined based on the units in the ENERGY STAR database, accessed February 2023.
2. Maximum idle energy rate is a function of interior volume. For the small size class, ENERGY STAR and high values were determined for a representative 7.8 ft^3 using the ENERGY STAR database, accessed February 2023. The typical value was assumed to be equivalent to the state standard for a representative 7.8 ft^3 unit.
3. Annual energy use is determined using the latest FEMP data from December 2021, which assumes that a typical 22.4 ft^3 commercial hot food holding cabinet uses an average of 9 hours per day and 365 days per year. The small size class is assumed to use the same number of annual usage hours as the medium size class.
4. Retail equipment costs were determined using distributor information for undercounter, half-size, and full-size hot food holding cabinets.
5. Additional installation costs and maintenance costs are negligible.

Note:
ENERGY STAR V. 2.0 went into effect in October 2011 and was revised in December 2022. Massachusetts, Nevada, and Rhode Island state standards have adopted the ENERGY STAR V. 2.0 criteria that went into effect in October 2011. The majority of state standards (California, Colorado, Connecticut, DC, Maryland, New Hampshire, Oregon, Rhode Island, Vermont, and Washington) implement the ENERGY STAR V. 1.0 specification that went into effect in August 2003, which is recorded in the table. ENERGY STAR V. 1.0 specifies a maximum idle energy rate of 40 W per cubic foot of interior volume.

Annual Maintenance Cost (2022$/kBtu/h)	–	–	–	–	–	–	–	–	–	–	–	–

1. Interior volume is characterized by the product size classes reported by ENERGY STAR. The large size class covers units with interior volume greater than or equal to 28 ft^3. Interior volume for the large size class was determined based on the units in the ENERGY STAR database, accessed February 1, 2023.
2. Maximum idle energy rate is a function of interior volume. For the large size class, ENERGY STAR and high values were determined using the ENERGY STAR database, and the typical value uses the assumption that ENERGY STAR units are reported to be 70% more efficient than typical units.
3. Annual energy use is determined using the latest FEMP data from December 2021, which assumes that a typical 22.4 ft^3 commercial hot food holding cabinet uses an average of 9 hours per day and 365 days per year. The large size class is assumed to use the same number of annual usage hours as the medium size class.
4. Retail equipment costs were determined using distributor information for undercounter, half-size, and full-size hot food holding cabinets.
5. Additional installation costs and maintenance costs are negligible.

Note:
ENERGY STAR V. 2.0 went into effect in October 2011 and was revised in December 2022. Massachusetts, Nevada, and Rhode Island state standards have adopted the ENERGY STAR V. 2.0 criteria that went into effect in October 2011. The majority of state standards (California, Colorado, Connecticut, DC, Maryland, New Hampshire, Oregon, Rhode Island, Vermont, and Washington) implement the ENERGY STAR V. 1.0 specification that went into effect in August 2003, which is recorded in the table. ENERGY STAR V. 1.0 specifies a maximum idle energy rate of 40 W per cubic foot of interior volume.

U21806-MNSC-CE-0771-Att 4

Commercial Hot Food Holding Cabinets

Final

Return to Table of Contents

- Hot food holding cabinets are used in commercial kitchens to keep food warm until it is served.
- While available in many shapes and sizes, interior volumes around 21.4 ft^3 were reported as typical in many settings in EIA Technology Forecast Updates (2018). FEMP currently lists 22.4 ft^3 as a representative unit size.
- Annual unit energy consumption can range from < 1,000 to > 30,000 kWh/y, depending on size, efficiency, and usage.
- Energy performance metric is "Idle Energy Consumption Rate" in Watts, measured using ASTM Standard F2140-11.
- There are no Federal standards for hot food holding cabinets, but seven States have identical standards.
  - The first State standard took effect in California in 2006; this standard is now considered the typical or "baseline" product. It is also equivalent to the ENERGY STAR V. 1.0 Specification that went into effect in August 2003.
  - ENERGY STAR V. 2.0 went into effect in October 2011.
- Maximum Idle Energy Consumption Rate for products $12 \leq V < 28$:
  - State standards: $\leq 40 \times V$ (baseline)
  - ENERGY STAR V. 2.0: $\leq 2.0 \times V + 254$ (about 65% below baseline)

  where V is interior volume in ft^3.
- The most efficient products are about 80% below baseline.
- Energy savings achieved with insulation, automatic door closers, magnetic door gaskets, and Dutch doors (half-doors).
- Advanced Case: Increased market incentives are expected to drive efficiency improvements. However, because cost does not scale with efficiency, there is no significant expected change in cost.

Objective

Final

The objective of this study is to develop baseline and projected performance and cost characteristics for residential and commercial end-use equipment.

- Examine 2012 and 2018 (commercial) and 2015 and 2020 (residential) baselines, as well as this year's baseline (2022).
  - Review literature, standards, installed base, contractor, and manufacturer information.
  - Provide a relative comparison and characterization of the cost and efficiency of a generic product.
- Forecast technology improvements that are projected to be available through 2050.
  - Review trends in standards, product enhancements, and research and development (R&D).
  - Project impact of product improvements and technology enhancement.

The performance and cost characterization of end-use equipment developed in this study will assist EIA in projecting national primary energy consumption.

Methodology

U21806-MNSC-CE-0771-Att 4

Final

Input from industry stakeholders, including government, R&D organizations, and manufacturers, was used to project product enhancements concerning equipment performance and cost attributes.

- Technology forecasting involves many uncertainties.
- Technology developments affect performance and cost forecasts.
- Varied sources ensure a balanced view of technology progress and the probable timing of commercial availability.

Definitions

Final

The following tables represent the current and projected efficiencies for residential and commercial building equipment ranging from the installed base in 2012 and 2018 (for commercial products) and 2015 and 2020 (for residential) to the highest efficiency equipment that is expected to be commercially available by 2050, assuming incremental adoption. Below are definitions for the terms used in characterizing the status of each technology.

- **Installed Stock Average**: the installed and *in use* equipment for that year. Represents the installed stock of equipment, but does *not* represent sales.
- **Current Standard**: the minimum efficiency (or maximum energy use) required (allowed) by current U.S. Department of Energy (DOE) standards, when applicable. For lighting, if no product exists at the standard efficiency level, a hypothetical wattage and lumen output is given for the standard's efficiency level.
- **ENERGY STAR®**: the minimum efficiency required (or maximum energy use allowed) to meet the ENERGY STAR® criteria, when applicable. Presented performance data represents certified products just meeting current ENERGY STAR specifications. For lighting, if no products exist at the ENERGY STAR efficiency level, a hypothetical wattage and lumen output is given for the ENERGY STAR efficiency level.
- **Low**: The minimum efficiency product or product mix available on the market. This rating typically reflects minimal compliance with DOE standards.
- **Typical**: the average, or typical, product being sold in the particular timeframe.
- **High**: the product with the highest efficiency available in the particular timeframe.
- **Lumens (lm):** the unit for luminous flux used in the SI unit system. This unit is used to indicate a light source's light output. All reported lumens are initial lumens. 1 kilolumen (klm) = 1,000 lumens.
- **Correlated Color Temperature (CCT)**: a specification of the color appearance of the light emitted by a lamp. Note: CCT is not a performance metric.
- **Color Rendering Index (CRI)**: a scale from 0 to 100 percent indicating how accurate a given light source is at rendering color when compared to a reference light source. The higher the CRI, the better the color rendering ability.
- **British thermal unit (Btu)**: a measure of the heat content of fuels or energy sources. It is the quantity of heat required to raise the temperature of one pound of liquid water by 1°F at the temperature that water has its greatest density (approximately 39 °F). 1 kBtu = 1,000 Btu.
- **Cubic Feet per Minute (CFM)**: a measure of airflow volume equal to the number of cubic feet of air flowing through a two-dimensional plane in one minute.
- **Not Available (N/A)**: data is not available where indicated.

Calculations

U21806-MNSC-CE-0771-Att 4

Final

The following metrics are commonly referred to throughout the tables to follow. Below are the calculations for each metric

— **Lighting**

- **System Wattage** = (Lamp Wattage * Ballast Factor) / Ballast Efficiency
- **System Lumens** = Lamp Lumens * Ballast Factor
- **Lamp Efficacy** = Lamp Lumens / Lamp Wattage
- **System Efficacy** = System Lumens / System Wattage
- **Lamp Cost ($/klm)** = Lamp Cost / (Lamp Lumens / 1,000)
- **Total Equipment Cost** = Lamp Cost + Fixture (including ballast) Cost
- **System Cost ($/klm)** = Total Equipment Cost / (System Lumens / 1,000). l/b/f denotes that the cost includes the luminaire, the ballast, and the fixture.
- **Total Installed Cost** = Total Equipment Cost + Labor Installation Cost
- **Ballast Luminous Efficiency (BLE)** = A/(1+B*Avg Total Lamp Arc Power^(-C)) where A, B, and C are pre-defined constants by DOE Energy Conservation Standards for Fluorescent Lamp Ballasts.

— **Commercial Refrigeration**

- **Nominal Capacity over Average Input (Btu in / Btu out)** = (Cooling or Heat Rejection Capacity)*24*365/(Annual Energy Consumption * 3,412)
- **Total Installed Cost** = Retail Equipment Cost + Labor Installation Cost
- **Total Installed Cost ($/kBtu/hour)** = Total Installed Cost*1,000 / (Cooling or Heat Rejection Capacity). h used as an abbreviation for hour throughout
- **Annual Maintenance Cost ($/kBtu/h)** = Annual Maintenance Cost * 1,000 / (Cooling or Heat Rejection Capacity)

— **Ventilation**

- **CFM out / Btu in / h** = System Airflow / (System Fan Power * 3,412)
- **Total Installed Cost ($/1,000 CFM)** = Total Installed Cost * 1,000 / System Airflow
- **Annual Maintenance Cost ($/1,000 CFM)** = Annual Maintenance Cost * 1,000 / System Fan Power

Market Transformation

The market for the reviewed products has changed since this analysis was performed in 2015. These changes are noted and reflected in the efficiency and cost characteristics.

- DOE issued federal minimum efficiency standards that have gone into effect for General Service Fluorescent Lamps (2012), Incandescent Reflector Lamps (2012), and Fluorescent Lamp Ballasts (2019).

- In April 2022, DOE codified into the Code of Federal Regulations the 45 lumens per watt (lm/W) backstop requirement for general service lamps that Congress prescribed in the Energy Policy and Conservation Act (10 CFR 430, 87 FR 27439). This action also amended the definition of general service lamps to include previously exempted product classes, such as reflector lamps. The rule will go into effect for manufacture and import in January 2023 and for retail and distribution in July 2023.

- DOE published a Final Rule updating energy conservation standards for Refrigerated Beverage Vending Machines at the end of 2015, effective in 2018. DOE also issued federal minimum efficiency standards that have or will soon go into effect for Refrigerated Beverage Vending Machines (2012), Automatic Commercial Ice Makers (2018), Walk-In Coolers and Freezers (2017), and Commercial Refrigeration Equipment (2017).

Residential Lighting

U21806-MNSC-CE-0771-Att 4

Performance and Cost Characteristics » Residential General Service Lamps

Final

The residential general service lamps characterized in this report are a 60-watt and a 75-watt medium screw-based (E26) A-type incandescent lamp and their halogen, CFL, and LED equivalents. A standard 60-watt incandescent lamp produces approximately 800 – 850 lumens. A standard 75-watt incandescent lamp produces approximately 1,100 lumens.

Performance:

- A majority of residential lamps have a nominal CCT rating of 2,700K and give off a warm, yellowish white color, but products with CCTs of 3,000K, 3,500K, 4,100K (neutral white), 5,000K (daylight), and 6,500K (blueish white) are also available. Traditional incandescent light bulbs have a nominal CCT of about 2,700K. When replacing a light bulb, it is advised to chose a product with a similar CCT value in order to achieve the same look.
- Incandescent and halogen lamps have perfect color rendering with a CRI value of 100. However, CFL and LEDs products commonly fall between 70 and 90 CRI, with an average around 80. CRI values of 80 are considered suitable for general illumination. High CRI products are preferable for retail and display applications where improved color quality is of real value. Higher CRI is not expected to be a focus for future LED products except for these specific retail and display applications.

Cost:

- Many factors influence the price of LED lamps including CRI, lifetime, dimming capabilities, and efficacy. Therefore, typical lamp prices in 2022 reflecting a mix of lamp characteristics and features were used as the basis for projections for both typical and high efficacy products in the future.
- Fixture prices and installation costs are not included for the residential sector. Labor costs are assumed to be negligible because homeowners likely replaces lamps themselves as they burn out. Therefore, total installed cost is the price of a lamp, and annual maintenance costs are the cost of replacing the lamps, which is a function of lamp life, lamp price, and the annual operating hours.
- Disposal costs are not characterized for residential lighting in this analysis. In residential cases, disposal is done by the occupant. Lamp and product burnout are assumed to result in no "added" cost aside from the work performed to install the replacement.

Legislation:

- The Energy Independence and Security Act of 2007 (EISA 2007) established standards for 60-watt general service lamps, effective in 2014, and 75-watt lamps, effective in 2013. These standards cannot be achieved by incandescent bulbs, but can be by halogen, CFL, and LED technologies.
- In April 2022, DOE codified into the Code of Federal Regulations the 45 lm/W backstop requirement for general service lamps that Congress prescribed in the Energy Policy and Conservation Act. This action also amended the definition of general service lamps to include previously exempted product classes, such as reflector lamps. These standards can not be achieved by traditional incandescent or halogen technologies currently on the market, and given current and projected trends in industry, they will likely not be met. It is currently assumed that industry will increase its investment in LED technology at the expense of incandescent, halogen, and CFL technologies. The rule will go into effect for manufacture and import in January 2023 and for retail and distribution in July 2023.

ENERGY STAR:

- For ENERGY STAR qualification, general service omnidirectional lamps must have a minimum lamp efficacy of 70 lm/W for products with CRI ≥ 90 and 80 lm/W for lamps with CRI < 90. Additionally, the lamps must have a CRI ≥ 80, nominal CCT of 2,700, 3,000, 3,500, 4,000/4,100, 5,000, or 6,000 K, and rated lifetime ≥ 10,000 hours (ENERGY STAR).

Performance and Cost Characteristics » Residential General Service Lamps

Final

Future Performance Improvements:

- Projections were provided for both typical and high performing products for 2030, 2040, and 2050. We assume manufacturers will focus on improving efficacy, lifetime, and price for products at constant CRI and CCT values.
- Due to continued R&D investment, competition from LED lighting products, and general market demand for cost-effective lighting, the performance and cost characteristics of conventional lighting technologies are expected to improve over the analysis period. However, the ability of these conventional technologies to react rapidly (in terms of performance improvement) to the emergence of a new light source such as LED lighting is relatively small because these are mature technologies (particularly incandescent, halogen, and fluorescent) and established market competitors (Navigant, 2019).
- For LED technology, efficacy, lifetime, and price improvements were based on the model described in the Energy Savings Forecast of Solid-State Lighting in General Illumination Applications (Navigant, 2019). For traditional technologies, the following future improvements were assumed to occur year over year through 2050:

Technology	Efficacy	Lifetime	Price	Potential for Improvements
Incandescent	0%	0%	-0.5%	Limited because the technology is mature and the technology cannot meet legislative requirements.
Halogen	0%	0%	-0.5%	Limited because the technology is mature and the technology cannot meet legislative requirements as of 2022.
CFL	+0.5%	0%	-0.5%	Improvements in efficacy can be made by using more rare-earth phosphors in compact fluorescent lamps.

Performance and Cost Characteristics » Residential Reflector Lamps

Final

The residential reflector lamps characterized in this report are directional lamps that emit approximately 550 – 850 lumens (except for LED PAR38s which have outputs up to 1,700 lumens). Multiple baseline reflector lamps were analyzed, including 65W Incandescent BR30, Halogen PAR30, Halogen Infrared Reflector (HIR) PAR30, CFL BR30, LED BR30, and LED PAR38.

Performance:

- A majority of residential lamps have a nominal CCT rating of 2,700K and give off a warm, yellowish white color, but products with CCTs of 3,000K, 3,500K, 4,100K (neutral white), 5,000K (daylight), and 6,500K (blueish white) are also available. Traditional incandescent light bulbs have a nominal CCT of about 2,700K. When replacing a light bulb, it is advised to chose a product with a similar CCT value in order to achieve the same look.
- Incandescent and halogen lamps have perfect color rendering with a CRI value of 100, but for CFL and LEDs products commonly fall between 70 and 90 CRI, with an average around 80. CRI values of 80 are considered suitable for general illumination, with high CRI products being preferable for retail and display applications where improved color quality is of real value. Higher CRI is not expected to be a focus for future LED products except for these very specific retail and display applications.

Cost:

- Many factors influence the price of LED lamps including CRI, lifetime, dimming capabilities, and efficacy.
- Fixture prices and installation costs are not included for the residential sector. Labor costs are assumed to be negligible because homeowners likely replaces lamps themselves as they burn out. Therefore, total installed cost is the price of a lamp, and annual maintenance costs are the cost of replacing the lamps, which is a function of lamp life, lamp price, and the annual operating hours.
- Disposal costs are not characterized for residential lighting in this analysis. In residential cases, disposal is done by the occupant. Lamp and product burnout are assumed to result in no "added" cost aside from the work performed to install the replacement.

Legislation:

- EPAct92 established minimum performance standards for some reflector lamps and provided exemptions for certain specialty applications (e.g., ER/BR, vibration service, more than 5% neodymium oxide, impact resistant, infrared heat, colored). EPAct92 effectively phased-out R-shaped tungsten filament incandescent reflector lamps at certain wattages and bulb diameters, replacing them with more efficient and cost effective tungsten-halogen parabolic aluminized reflector (PAR) lamps. EISA 2007 took away certain exemptions from EPACT 1992, requiring certain previously exempted lamps to meet EPAct92 minimum performance standards by January 1, 2008. The 65W BR30, a large majority of the incandescent reflector lamp market, was still exempted until 2022.
- In April 2022, DOE codified into the Code of Federal Regulations the 45 lm/W backstop requirement for general service lamps that Congress prescribed in the Energy Policy and Conservation Act. **This action also amended the definition of general service lamps to include previously exempted product classes, such as reflector lamps.** These standards can not be achieved by traditional incandescent or halogen technologies currently on the market, and given current and projected trends in industry, they will likely not be met. It is currently assumed that industry will increase its investment in LED technology at the expense of incandescent, halogen, and CFL technologies. The rule will go into effect for manufacture and import in January 2023 and for retail and distribution in July 2023.

Performance and Cost Characteristics » Residential Reflector Lamps

Final

ENERGY STAR:

- For ENERGY STAR qualification, general service, reflector lamps must have a minimum lamp efficacy of 61 lm/W for products with CRI ≥ 90 and 70 lm/W for lamps with CRI < 90, respectively. Additionally, the lamps must have a CRI ≥ 80, nominal CCT of 2,700, 3,000, 3,500, 4,000/4,100, 5,000, or 6,000 K, and rated lifetime ≥ 10,000 hours (ENERGY STAR).

Future Performance Improvements:

- Projections were provided for both typical and high performing products for 2030, 2040, and 2050. We assume manufacturers will focus on improving efficacy, lifetime, and price for products at constant CRI and CCT values.
- Due to continued R&D investment, competition from LED lighting products, and general market demand for cost-effective lighting, the performance and cost characteristics of conventional lighting technologies are expected to improve over the analysis period. However, the ability of these conventional technologies to react rapidly (in terms of performance improvement) to the emergence of a new light source such as LED lighting is relatively small because these are mature technologies (particularly incandescent and fluorescent) and established market competitors (Navigant, 2019).
- For LED technology, efficacy, lifetime, and price improvements were based on the model described in the Energy Savings Forecast of Solid-State Lighting in General Illumination Applications (Navigant, 2019). For traditional technologies, the following future improvements were assumed to occur year over year through 2050.

Technology	Efficacy	Lifetime	Price	Potential for Improvements
Incandescent	0%	0%	-0.5%	Limited because the technology is mature and the technology cannot meet legislative requirements.
Halogen	0%	0%	-0.5%	Limited because the technology is mature and the technology cannot meet legislative requirements as of 2022.
CFL	+0.5%	0%	-0.5%	In addition to higher efficiency reflector coatings, improvements in efficacy can be made by using more rare-earth phosphors in compact fluorescent lamps. Lifetime improvements can be made by improving the compact fluorescent lamp electrodes.

1. Halogen PAR30 lamps were previously exempted from the EISA 2007 GSL definition until DOE's new final rule in 2022. The new definitions go into effect in 2023. Note: product offerings are very limited in 2022.
2. In April 2022, DOE codified into the Code of Federal Regulations the 45 lm/W backstop requirement for general service lamps that Congress prescribed in the Energy Policy and Conservation Act. The new minimum efficacy requirements go into effect for manufacture and import in January 2023 and for retail and distribution in July 2023. This Final Rule also amended the definition of GSLs to include previously exempted product classes, including reflector lamps. These standards cannot be met with halogen technologies.

Performance and Cost Characteristics » Residential 4-foot Linear 2-Lamp Lighting Systems

Final

This section characterizes commercial linear fixtures that house two 4ft long linear lamps and their integrated luminaire equivalents. The technologies available for this system are linear fluorescent and LED.

- T5 lamps are approximately 40% narrower than T8 lamps and almost 60% narrower than T12 lamps. This narrowness allows T5 lamps to be coated with higher quality, more efficient phosphor blends than larger diameter lamps, resulting in a more efficacious lamp. The compact size of T5 lamps also permits greater flexibility in lighting design and construction.
- LED options for linear fixtures include replacement lamps that can fit directly into an existing fixture and fully integrated luminaires that can be used to replace existing fixtures. LED replacement lamps are also known as TLEDs. Type A TLEDs can be installed with existing ballasts and Type B and C TLEDs require the ballast to be disconnected. Replacement lamps are only sold to go into existing fixtures. If a new fixture is to be installed, a fully integrated LED luminaire is a more cost effective and efficient option. Because LED luminaires are fully integrated, they do not have lamp or fixture efficiency losses associated with ballasts and fixture optics.

Performance:

- Residential linear lamps often have a nominal CCT rating of 3,500K, but products with CCTs of 3,000K, 4,000K, and 4,100K (neutral white) are also common. 5,000K (daylight) lamps are available as well. When replacing a light bulb, it is important to choose a product with a similar CCT value to achieve the same look.
- Incandescent and halogen lamps have perfect color rendering with a CRI value of 100, but for CFL and LEDs products commonly fall between 70 and 90 CRI, with an average around 80. CRI values of 80 are considered suitable for general illumination, with high CRI products being preferable for retail and display applications where improved color quality is of real value. Higher CRI is not expected to be a focus for future LED products except for these very specific retail and display applications.

Cost:

- Many factors influence the price of LED lamps including CRI, lifetime, dimming capabilities, and efficacy. Therefore, typical lamp prices in 2022 reflecting a mix of lamp characteristics and features were used as the basis for projections for both typical and high efficacy products in the future.
- The total installed cost is the price of a lamp, ballast (if applicable), and fixture plus the cost for labor associated with the installation, except for in the case of LED replacement lamps, which are sold only as a replacement for use in an existing fixture. The LED luminaire is more efficient and cost effective for new installations or fixture retrofits.
- Labor costs for lamp changes are assumed to be negligible because homeowners likely replace lamps themselves as they burn out. Therefore, annual maintenance costs are the cost of the replacement lamp itself. The frequency at which lamps are replaced is a function of lamp life and the annual operating hours for residential linear systems.
- Disposal costs are not characterized for residential lighting in this analysis. In residential cases, disposal is done by the occupant. Lamp and product burnout are assumed to result in no "added" cost aside from the work performed to install the replacement.

Legislation:

- Beginning July 14, 2012 (or July 14, 2014, for T8 700-series phosphor lamps), DOE fluorescent lamp standards required a minimum efficacy of 89 lm/W. Although the amended performance-based standards do not explicitly prohibit T12 lamps, no T12 lamps met the standard at the time of its announcement. Since then, however, T12 lamps meeting the standard have entered the market.
- Beginning November 14, 2014, DOE standards required that the characterized residential ballasts have a minimum BLE = 0.993 / (1 + 0.41 * Avg Total Lamp Arc power ^ (- 0.25)). Residential ballasts also must have a minimum power factor of 0.5.
- California's Title 24 mandates the use of electronic ballasts with high efficacy luminaires (including fluorescent) of 13 W or higher (CEC, 2005).

ENERGY STAR:

- ENERGY STAR does not cover linear lamps. (ENERGY STAR, 2020)

Performance and Cost Characteristics » Residential 4-foot Linear 2-Lamp Lighting Systems

Final

Future Performance Improvements:

- Projections were provided for both typical and high performing products for 2030, 2040, and 2050. We assume manufacturers will focus on improving efficacy, lifetime, and price for products at constant CRI and CCT values.
- Due to continued R&D investment, competition from LED lighting products, and general market demand for cost-effective lighting, the performance and cost characteristics of conventional lighting technologies are expected to improve over the analysis period. However, the ability of these conventional technologies to react rapidly (in terms of performance improvement) to the emergence of a new light source such as LED lighting is relatively small because these are mature technologies (particularly incandescent and fluorescent) and established market competitors (Navigant, 2019).
- For LED technology, efficacy, lifetime, and price improvements were based on the model described in the Energy Savings Forecast of Solid-State Lighting in General Illumination Applications (Navigant, 2019). For traditional technologies, the following future improvements were assumed to occur year over year through 2050:

Technology	Efficacy	Lifetime	Price	Potential for Improvements
T12	0%	0%	-0.5%	Limited because the technology is mature.
T8	0%	0%	-0.5%	Limited because the technology is mature.
T5	0%	0%	-0.5%	Limited because the technology is mature.

1. Data and assumptions taken from the 2018 SSL Forecast. The report states that efficacy improvements for T8 lamps are not expected in the future, and that the cost for all commercial fixtures is expected to decrease between 0.1%-0.6% per year. We use 0.5% per year here.
2. From 2020 to 2050, fixture (and fixture price) includes ballast.

Note: Assume no labor is associated with lamp replacement in the residential sector because residents likely replace lamps themselves.

1. N/A because the lamp and fixture are both included in the luminaire.

Performance and Cost Characteristics » Residential Outdoor Lamps

Final

- The residential outdoor lamps characterized in this report include reflector and general service lamps used for security and/or porch lighting that can be switched on from inside the home (i.e. parking lot/garage and outdoor common area lighting at multifamily buildings are excluded) with lumen outputs of approximately 1,000 – 1,400 lumens. Multiple baseline lamps were analyzed according to estimates of installed base average lumens by lamp type, including:

Security (Reflector Lamps)	Porch (General Service Lamps)
Incandescent BR30	Incandescent A-Type
Halogen PAR38	Halogen A-Type
Halogen Infrared Reflector (HIR) PAR38	CFL Bare Spiral
CFL PAR38	LED A-Type Lamp
LED PAR38	

Performance:

- 65W BR30 is the only viable incandescent reflector lamp due to exemption from EISA 2007. The lumen output of this lamp type is well below other reflector lamp technologies characterized for residential outdoor spaces, thus its use is limited for this application. This product is, as of 2022, expected to be eliminated by DOE's 45 lm/W backstop requirement.
- A majority of residential lamps have a nominal CCT rating of 2,700K and give off a warm, yellowish white color, but products with CCTs of 3,000K, 3,500K, 4,100K (neutral white), 5,000K (daylight), and 6,500K (blueish white) are also available. Traditional incandescent light bulbs have a nominal CCT of about 2,700K. When replacing a light bulb, it is advised to chose a product with a similar CCT value in order to achieve the same look.
- Incandescent and halogen lamps have perfect color rendering with a CRI value of 100. However, CFL and LEDs products commonly fall between 70 and 90 CRI, with an average around 80. CRI values of 80 are considered suitable for general illumination. High CRI products are preferable for retail and display applications where improved color quality is of real value. Higher CRI is not expected to be a focus for future LED products except for these specific retail and display applications.

Cost:

- Many factors influence the price of LED lamps including CRI, lifetime, dimming capabilities, and efficacy. Therefore, typical lamp prices in 2015 reflecting a mix of lamp characteristics and features were used as the basis for projections for both typical and high efficacy products in the future.
- Fixture prices and installation costs are not included for the residential sector. Labor costs are assumed to be negligible because homeowners likely replaces lamps themselves as they burn out. Therefore, total installed cost is the price of a lamp, and annual maintenance costs are the cost of replacing the lamps, which is a function of lamp life, lamp price, and the annual operating hours for residential reflector lamps.
- Disposal costs are not characterized for residential lighting in this analysis. In residential cases, disposal is done by the occupant. Lamp and product burnout are assumed to result in no "added" cost aside from the work performed to install the replacement.

Performance and Cost Characteristics » Residential Outdoor Lamps

Final

Legislation:

- In April 2022, DOE codified into the Code of Federal Regulations the 45 lm/W backstop requirement for general service lamps that Congress prescribed in the Energy Policy and Conservation Act. **This action also amended the definition of general service lamps to include previously exempted product classes, such as reflector lamps.** These standards can not be achieved by traditional incandescent or halogen technologies currently on the market, and given current and projected trends in industry, they will likely not be met. It is currently assumed that industry will increase its investment in LED technology at the expense of incandescent, halogen, and CFL technologies. The rule will go into effect for manufacture and import in January 2023 and for retail and distribution in July 2023.

ENERGY STAR:

- For ENERGY STAR qualification, general service omnidirectional lamps must have a minimum lamp efficacy of 70 lm/W for products with CRI ≥ 90 and 80 lm/W for lamps with CRI < 90.
- For ENERGY STAR qualification, general service reflector lamps must have a minimum lamp efficacy of 61 lm/W for products with CRI ≥ 90 and 70 lm/W for lamps with CRI < 90.
- Additionally, the lamps must have a CRI ≥ 80, nominal CCT of 2,700, 3,000, 3,500, 4,000/4,100, 5,000, or 6,000 K, and rated lifetime ≥ 10,000 hours (ENERGY STAR).

Future Performance Improvements:

- Projections were provided for both typical and high performing products for 2030, 2040, and 2050. We assume manufacturers will focus on improving efficacy, lifetime, and price for products at constant CRI and CCT values.
- Due to continued R&D investment, competition from LED lighting products, and general market demand for cost-effective lighting, the performance and cost characteristics of conventional lighting technologies are expected to improve over the analysis period. However, the ability of these conventional technologies to react rapidly (in terms of performance improvement) to the emergence of a new light source such as LED lighting is relatively small because these are mature technologies (particularly incandescent and fluorescent) and established market competitors (Navigant, 2019).
- For LED technology, efficacy, lifetime, and price improvements were based on the model described in the Energy Savings Forecast of Solid-State Lighting in General Illumination Applications (Navigant, 2019). For traditional technologies, the following future improvements were assumed to occur year over year through 2050.

Technology	Efficacy	Lifetime	Price	Potential for Improvements
Incandescent Omnidirectional	0%	0%	-0.5%	Limited because the technology is mature and the technology cannot meet legislative requirements.
Incandescent Directional	0%	0%	-0.5%	Limited because the technology is mature and the technology cannot meet legislative requirements.
Halogen	0%	0%	-0.5%	Limited because the technology is mature and the technology cannot meet legislative requirements.
CFL	+0.5%	0%	-0.5%	In addition to benefiting from higher efficiency reflector coatings, improvements in efficacy can be made by using more rare-earth phosphors in compact fluorescent lamps. Lifetime improvements can be made by improving the compact fluorescent lamp electrodes.

1. Incandescent BR30 lamps were previously exempted from DOE Incandescent Reflector Lamp standards and the EISA 2007 general service lamp definition until DOE's new final rule in 2022. The new definitions go into effect in 2023.
2. In April 2022, DOE codified into the Code of Federal Regulations the 45 lm/W backstop requirement for general service lamps that Congress prescribed in the Energy Policy and Conservation Act. The new minimum efficacy requirements go into effect for manufacture and import in January 2023 and for retail and distribution in July 2023. This Final Rule also amended the definition of GSLs to include previously exempted product classes, including reflector lamps. These standards cannot be met with incandescent technologies.

1. 2015 and 2020 data calculated based on 2009 installed stock data and the following assumptions: Efficacy +0.5%/y, Cost -0.5%/y (NCI, 2019)
2. Virtually all manufacturers have discontinued manufacturing of CFL reflector lamps in favor of LEDs. Distributor offerings for CFL reflectors have been eliminated.
3. In April 2022, DOE codified into the Code of Federal Regulations the 45 lm/W backstop requirement for general service lamps that Congress prescribed in the Energy Policy and Conservation Act. The new minimum efficacy requirements go into effect for manufacture and import in January 2023 and for retail and distribution in July 2023. This Final Rule also amended the definition of GSLs to include previously exempted product classes, including reflector lamps. Although these standards can be met with CFL technology, manufacturers have discontinued manufacturing CFL reflector lamps in favor of LEDs.
