Over the past five years, a number of hydropower portfolios have traded hands. Here is a partial list of those with information publicly available:

- 2022 – Hydro-Quebec purchases Great River Hydro LLC's portfolio of 13 generating stations with capacity to generate 589 megawatts. Total price $2 billion.
- 2019 – Ontario Power Generation purchases Cube Hydro's portfolio of 19 hydropower facilities with a combined capacity of 385 megawatts. Total price $1.2 billion
- 2022 - Confidential transaction WSP performed services to include a portfolio of three vintage plants with combined capacity of 14 megawatts. Total price $30 million.

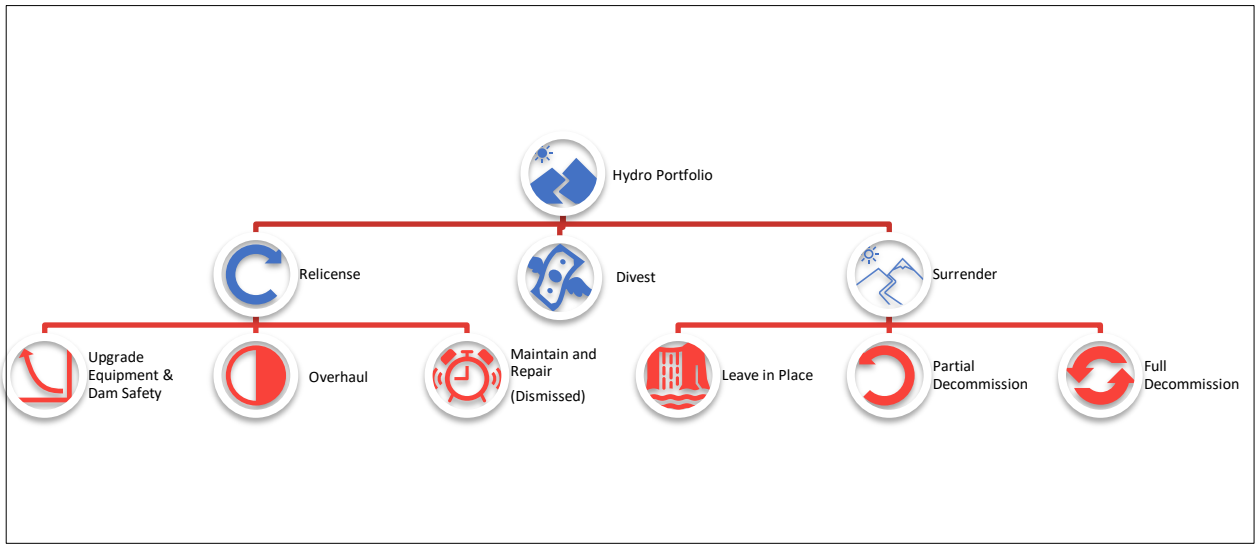

Figure 1. Decision Tree for the Scenarios Considered

4 RISK AND DECISION MATRIX

Table 3 summarizes WSP's decision matrix risk attributes, their definition, and the risk levels that we used to score each hydropower project. Risk categories to Consumers include Environment, Dam Safety, Economics, People, and Reputation, all weighted equally for this exercise. Levels of risk ranged from none (green), low (yellow), moderate (orange), and high (red). Risks are interpreted as current situation and under the future scenario (relicense or surrender with subcategory options). Results of each site's risk matrix is provided in section *8 Results and Interpretation.*

Table 3. Risk and Decision Matrix

Risk Attribute	Criteria Definition	Color Assessment
Environment	Risks could include required mitigation measures and responsibilities such as failure to meet water temperature and dissolved oxygen standards or compliance, toxic sediments, invasive species, fish passage, and federal agency mandatory conditions.	**Green** – All environmental concerns would be addressed through enactment of the scenario. **Yellow** – Most environmental concerns would be addressed. **Orange** – Most environmental concerns will not be addressed without some management/ mitigation being implemented with the scenario. **Red** – Environmental concerns would remain unchanged or pose an additional risk to Consumers.
Dam Safety	Risks include the regulatory requirements to upgrade the structures and/or modify operations	**Green** – No FERC Part 12 issues, no structural issues in condition assessment, no spillway issues **Yellow** – Small or easily remedied FERC Part 12 issues, or issues in condition assessments or spillway **Orange** – Moderate FERC Part 12 issues, important repairs recommended in condition assessments, potential risks associated with not passing the Inflow Design Flood. **Red** – Significant FERC Part 12 issues, unable to pass the Inflow Design Flood, urgent needs identified in condition assessments.

Risk Attribute	Criteria Definition	Color Assessment
Economics	Positive or Negative net present values with the calculated NPV included for reference	**Green** – Net Present Value is positive. **Orange** – NPV could be positive or better than the negative NPV in red. Typically used for Divest scenario. **Red** – Net Present Value is negative.
People	Includes Consumers staff (e.g., operators), contractors, and the public (e.g., downstream, shoreline property owners, commercial connections).	**Green** – employees of Consumers are safe when working on site; contractors are safe when working on site, public is safe when recreating at facilities. **Yellow** – creates somewhat safe conditions for Consumers employees, contractors and public. **Orange** – creates moderately unsafe conditions for Consumers employees, contractors and public. **Red** – creates unsafe working conditions for Consumers employees, contractors, downstream properties, and the public
Reputation	Includes consideration of duration and intensity of potential positive or negative reflection on Consumers' reputation.	**Green** – very positive **Yellow** – somewhat positive **Orange** – somewhat negative **Red** – very negative

5 ROAD MAP FOR SCENARIOS

5.1 RELICENSE

Under this option, Consumers commits to upholding its responsibility to maintain and operate the dams including all conditions of the future licenses for an assumed 50-year period. FERC license holders are responsible for implementing the conditions in each license as well as meet FERC dam safety requirements as long as the license is active. Relicensing requires continuing to maintain dam safety compliance, which depending on the timing or regulations could be full spillway replacement to Risk Informed Decision Making (RIDM). Additional costs associated with relicensing include upgrades to the generating equipment to maximize generation as well as constructing license terms and conditions which could include new requirements to add fish passage, improve water quality conditions, and enhance recreation resources. The following subsections list some of the steps taken ahead of applying for a new FERC license, maintaining compliance with dam safety requirements and potential upgrades or overhauls to the turbine generator equipment to maximize revenue during a future license term.

5.1.1 RELICENSING STEPS

- Define internal strategy, overall plan, licensing process, and schedule (assumes Integrated Licensing Process by river system).
- Prepare plan for relicensing processes (e.g., resource studies, operational and dam safety proposals) and proposal for future license.
- Prepare stakeholder list and proposed enhancements at the projects to capture in licensing (e.g., upgrades, operational changes, land/water management).
- Decide on turbine upgrades or repairs to propose in the licensing process, if not before. The process for this is discussed below in 5.1.3 Generation Enhancement Steps
- Conduct early outreach to stakeholders for existing data to include in the Pre-Application Document.
- Prepare Pre-Application and Notice of Intent, and file with FERC.
- Complete FERC Scoping, Study Planning and Execution, Field Data Collection, Reporting and Development of preliminary Protection, and Mitigation and Enhancement (PMEs) measures for Draft License Applications.
- Complete discussions and strategy around PMEs and evaluate pursuing settlement agreement(s).
- Finalize License Applications.
- Implement license conditions and overall compliance.

The timing of implementing the pre-license strategy through the application filing with FERC typically occupies the better part of seven years prior to the license expiration date. Given the number of projects expiring at the same time within the river hydropower portfolio, additional time may be required ahead of starting. Certain pre-filing activities could prove useful and efficient during the licensing process such as work to develop standardized project descriptions and understandings. Currently, there are a wide range of sources to review. Preparing templates and reference information for each project would reduce

introducing errors during the relicensing process that could cause confusion or delays from FERC if there are inconsistencies in the exhibits.

5.1.2 DAM SAFETY STEPS

- Review current FERC dam safety regulations, i.e., new Part 12D inspection guidance, including Comprehensive Assessments which require risk assessment and restarting the Potential Failure Mode Analyses (PFMA) process.
- Conduct a thorough review of existing documentation (FERC Dam Safety Commitments, compliance), PFMA, Probable Maximum Flood (PMF) studies, spillway gate certifications, Dam Safety and Surveillance Monitoring Programs and Reports, Stability Analyses (embankment, spillway, powerhouse, etc.), Emergency Action Plans, etc. to identify current dam safety non-compliances on file with FERC and whether any additional dam safety non-compliances may exist.
- Review the Strategy Projection to confirm that identified dam safety non-compliance issues are scheduled to be addressed.
- Complete projects to address dam safety non-compliances.

5.1.3 GENERATION ENHANCEMENT, OPERATION, AND MAINTENANCE STEPS

Consumers regularly completes system health assessments for all their mechanical and electrical equipment, much of which is still original equipment. The facilities were designed as peaking units but are now operated as run of river facilities. As a result, the existing equipment is inefficient much of the year based on available river flows compared to runner efficiency curves. Consumers recognizes there is opportunity to improve the generation units and increase the efficiencies and resulting revenues. If the decision is not to upgrade the units but to repair the units with similar, in-kind equipment, the life of the unit could be similarly extended another 20-30 years. Part of evaluating the generation equipment and developing a plan of action would fall under an Enhancement, Operation and Maintenance strategy. This strategy and process requires internal and external resources to execute the upgrades or repairs and ensure the regulatory process is followed. Overall, the process breaks down into eight (8) main phases:

1. Diagnosis as a prerequisite to the strategy
2. Definition of the objectives of the strategy
3. Define actions for building the strategy
4. Evaluate strategic models for executing the strategy
5. Evaluate the organizational structure and close the gaps
6. Financial costs estimate of the O&M strategy
7. Perform a cost-benefit analysis to validate strategy
8. Implementation of the strategy and control

5.1.4 ISSUES/RISKS

Future license conditions are consistently more financially burdensome than current license conditions and environmental and dam safety regulations have become more rigorous over time which is expected to continue under a future license. Important issues and additional risks to accommodate in future licenses could include:

- Dam Safety Regulations such as:
  - Enhanced regulations, new design requirements (to RIDM)
  - Ongoing aging of the facilities (maintaining safe operating conditions)
  - Regular dam safety inspections, monitoring, and repairs
  - Requirements to monitor and report on operations
- Environmental Protection, Mitigation, and Enhancement Measures such as:
  - Requirements to add fish passage, restrict invasive species, or stock fish
  - Requirement to improve water quality (temperature and dissolved oxygen)
  - Requirements to enhance and/or expand recreation resources
  - Requirements to enhance wildlife/aquatic/wetland habitats
  - Requirements to minimize shoreline erosion
  - Limitations on peaking/formalization to run-of-river operations, seasonal scheduled outages to allow downstream passage of juvenile fish
  - Requirements for regular monitoring, reporting and consultation on environmental, recreation and potential removal plans throughout the course of the subsequent license.

5.1.5 NOTES

- Settlement agreements are negotiated agreements between the licensee and agencies on operational, protection, enhancement, or mitigation measures to include in a future license.
- Settlement agreements are typically not utilized to de-risk dam safety requirements.

5.2 SURRENDER

The three surrender scenarios would follow a similar process as relicensing as far as the execution of a work plan because the process is similar in it requires FERC approval. The following list summarizes the steps while the following subsections detail the process.

- Define internal strategy, overall plan, surrender process, and schedule.
- Prepare plan for surrender processes (e.g., resource studies, operational and dam safety proposals) and proposal for future restoration/conditions.
- Prepare stakeholder list and proposed outcomes at the projects to capture in the surrender (e.g., non-generation, partial removal, full removal with restoration).

- Conduct early outreach to stakeholders for existing data to include in the Initial Consultation Document.
- Prepare Initial Consultation Document and Notice of Intent, and file with FERC.
- Complete Study Planning and Execution, Field Data Collection, Reporting and Development of preliminary Protection, and Mitigation and Enhancement (PMEs) measures for surrender applications.
- Complete discussions and strategy around PMEs and evaluate pursuing settlement agreement(s).
- Finalize Surrender Applications.
- Implement surrender conditions and overall compliance.

5.2.1 PRELIMINARY SITE INVESTIGATIONS

- One of the unknowns in the surrender scenario is the potential costs required to manage and dispose of potentially contaminated sediments upstream of the structures. While some sites (Mio and Calkins Bridge) are suspected to have a high probability to contain contaminated sediments upstream from the reservoirs, there is not have enough information related to sediment contamination within the reservoirs to drive the decisions at this time. Sediment investigations would occur after a decision to surrender and decommission were approved.

5.2.2 INTERNAL STRATEGY, OVERALL SURRENDER PLAN, PROCESS, AND SCHEDULE

An initial surrender plan, including identification of the preferred scenario for surrender, would be identified by Consumers with a general scope and schedule generated. This information would guide Consumers in the execution of the evaluations and process required for the license surrender and can be used to notify FERC of Consumers' intent to surrender the license. This early notification would begin the multi-year evaluation process of the surrender scenario for execution. It is anticipated that the overall surrender process, regardless of the selected surrender scenario, would take 8-10 years to execute to allow the environmental studies and stakeholder outreach to be conducted, preparation of engineering evaluations and development of bid documents, permitting, and moving through the overall FERC decommissioning process. Schedule is discussed in more detail in section 10, *Timeline.*

5.2.3 PREPARE STAKEHOLDER LIST, INITIATE CONSULTATION AND COMMUNICATE PLANS, FILE NOTICE OF INTENT WITH FERC

Prepare formal stakeholder list required for execution of the surrender, which would include federal, state, and local representatives for regulatory, environmental, and socioeconomic evaluations. With Consumers overall surrender plan and schedule, submit notifications to agencies and stakeholders of the intent to surrender and commence with stakeholder meetings for issues and concerns that would feed into detailed site assessments as part of the overall FERC surrender process. Consultation process provides stakeholders opportunity to provide input or even influence removal conditions or requirements. Results from the consultation and study process would inform the development of a final license surrender application.

5.2.4 CONDUCT ENVIRONMENTAL SITE INVESTIGATIONS AND STUDIES

In coordination with FERC, engineering and environmental assessment evaluations would be carried out in order to proceed with the decommissioning process. Studies would be variable based on the scenario and site; however, it is anticipated fisheries (ecology and biology of upstream and downstream reaches) and hydrologic/hydraulic assessments would be required for each surrender scenario. Additional evaluations for the partial and full removal scenarios should include evaluations for soils and sediments (physical and chemical) to understand management and disposal options, cultural investigations[2] (which may require Phase I, Phase II and Phase III assessments), vegetation condition assessments (including wetland delineation and non-native vegetation assessment surveys), and stream assessments to aid in the design of the restored channel footprints and adjacent floodplains.

5.2.5 EVALUATE ALTERNATIVES AND PREPARE PRELIMINARY DECOMMISSIONING PLANS AND CONDUCT DETAILED STAKEHOLDER CONSULTATION

Following site evaluations, evaluate decommissioning alternatives for the Environmental Impact Statement (EIS) and prepare preliminary decommissioning designs/plans for permits and consultation with stakeholders. Initiate stakeholder consultation to review preliminary decommissioning plans to present findings and plan of action forward. Obtain input ahead of permit application submissions to guide FERC findings in the EIS and address major hurdles in the approach prior to permit applications and formal public review processes.

5.2.6 PREPARE FINAL SURRENDER APPLICATION TO FERC

Upon filing the final application to FERC, FERC would determine if Environmental Assessment (EA) or an EIS are needed to assess the potential impacts of surrender and decommissioning on power needs, environmental resources, cultural and historic resources, land use, recreational resources, and socioeconomic resources in the vicinity of the project. Due to the size of these facilities and potential impacts, it is anticipated an EIS would be required for both the partial and full removal scenarios where an EA may be suitable for the no-power generation scenario. Once FERC satisfies their NEPA requirements they would issue a Surrender Order detailing the conditions required by FERC that must be accomplished to surrender the license.

[2] Archaeological and cultural surveys are the most common form of compliance with Section 106 of the National Historic Preservation Act. Phase I surveys involve the identification and assessment of both archaeological resources and historic structures. Phase II is further investigation and includes testing and evaluations. Phase III efforts are the most intense level of archaeological investigation in includes data recovery and site mitigation.

5.2.7 FINALIZE PLAN OF ACTION AND APPLY FOR APPLICABLE LOCAL, STATE, AND FEDERAL REGULATORY PERMITS FOR EXECUTION

Following detailed stakeholder coordination on the decommissioning plans and receiving comments, address comments with the decommissioning approach and complete formal design/documents required for execution and regulatory approvals. Document comments and response plans and include with applicable permit applications as well as providing to FERC consistent with decommissioning orders.

5.2.8 IMPLEMENT PLANS AND FERC DECOMMISSIONING ORDERS

With receipt of regulatory approvals and following environmental assessments/stakeholder documentation, FERC decommissioning orders should be obtained, and plans executed.

5.3 DIVEST

Following internal approvals to pursue putting the assets up for sale, an engineering firm familiar with owners' representation and due diligence would be hired to assist in preparing the materials interested buyers would review as part of the transaction. Materials would include generation records, inspection reports, safety information, condition assessments, and financial records.

6 SITE SUMMARIES

WSP compiled baseline information related to existing license conditions, forecast license conditions, existing dam safety and long-term financial plan activities as well as economic modeling results into a complete package for each site. The full site summary for each site is included in Appendix B.

7 ECONOMIC MODEL

7.1 INTRODUCTION

In order to assess the options concerning each of its 13 dams, a financial model was assembled to quantify the financial outcomes from the relicense and surrender scenarios. A Divest scenario (sale of the asset) has not been analyzed at this stage; for a future stage an asset valuation could be developed to consider the Divest scenario. This financial model captures the capital expenditures (CapEx), operational expenditures (OpEx or O&M), and potential revenues, and converts reasonable cost, revenue, and time assumptions into cashflow over a 50-year life cycle and pulls it to a present-day Net Present Value (NPV). This model was developed to analyze the financial value to Consumers of relicensing or surrendering the license as a viable investment. The WSP technical and economic model team worked together to arrive at reasonable assumptions, which are noted below. In addition to using the estimated cost and revenue figures a sensitivity analysis was run for every scenario. It is worth noting here that given the high capital costs and little revenue, in all cases the result is a negative NPV for the 13 dam sites for all the scenarios.

The NPV varies significantly depending on the scenario. As part of the sensitivity, the cost and revenues were manipulated to the point where a NPV of zero could be achieved. A NPV of zero means that a break-even point has been achieved for a dam based on the discounted cash flow of cost and revenues. Under this condition, and for a given scenario and dam one can evaluate at what rate the expected produced energy would have to be sold/raised to break-even. This type of sensitivity analysis provides context for understanding the long-term economic impact of the proposed alternatives.

Given the high variability inherent on the cost and expected revenue inputs, any conclusions formed with the use of the model shall be considered preliminary, and subject to a more detailed cost and lifecycle analysis. Furthermore, due consideration must be placed on qualitative aspects of risks, economics, and benefits which are outside of the scope of these economic models.

Consumers Energy used the models produced by WSP to add additional details such as overheads, updated escalation and discount rates (which matched those used by Consumers Energy), added in energy capacity value, updated revenue rates to reflect assumptions used in their IRP for years beyond 2050, and added a general capital line for anticipated, yet undefined capital costs at each site based on more recent trends in capital project spend at Consumers Energy hydropower sites. The intent of this exercise was to see how the model results changed when incorporating overheads and revenue for capacity, while also adding in some of the other known unknowns regarding overall hydro expenses.

7.2 GENERAL MODEL ASSUMPTIONS

The economic model of each site was built in a MS Excel file, where relevant project cost assumptions are input and converted into a cashflow of costs and revenues. The spreadsheets of the model are structured in a logical way by singling out inputs, escalation, timing, expenses, revenues and NPV (the model outcome). WSP employed a combination of approaches to populating and running the model.

Model inputs were derived from Consumers historical and near-term projections identified in the strategic plan and verified by literature review. Initially, Consumers 10-year Strategy Projection was reviewed for projected operations and maintenance as well as large Capital projects. The Strategy Projection was evaluated, and project costs distributed to the corresponding dam's economic model, feeding both the short-term capital investments (named “Maintain and Repair projects” in the economic model), as well as major project expenses such as spillway replacement or other major initiatives (named “Project Major Maintenance/Rehabilitation Expenses” in the economic model), and finally an acknowledgement that ongoing OpEx costs would be required during the future term of the license (calculated as a percentage of the Strategic Projections and applied to future years). Prior to using the information, the WSP team conducted an independent review of hydropower literature from federal sources to confirm Consumers estimated spend was accurate enough for inclusion in the model regarding the major costs or investments. The model was constructed with assumptions on costs for projects beyond 10 years to account for the age of the assets and need to maintain them for operation under a future license. Current Strategy Projection projects across the entire hydropower portfolio are a good representation of the types of maintenance projects the assets will require, such as dam safety inspections, concrete repairs, generator rewinds, etc. This basket of projects and associated costs are the types of projects that would occur during the future license, so our team assumed related expenses every ten years after relicense, with an additional expense half-way through the term, this is, at years 10, 20, 25 (half way), 30, 40 and 50. Although this approach didn’t identify specific projects because those are unknown at this time, it recognizes there would be projects and assigns costs for future Capital Projects. Future iterations could include a suite of defined projects or refined costs to improve on the comparative outputs. In the end all dams exhibited a negative NPV. Exploring additional CapEx project spends or adding additional projects or higher project costs generate larger negative NPV. Appendix A discusses WSP’s independent review of costs. In addition, for the surrender and decommission scenarios, WSP built cost estimates from our experience with dam removals and anticipated issues at each project site. All Strategy Projection costs and decommissioning costs used in the model do not include any Consumers Energy Overheads for construction management or reviews to be consistent with industry estimates.

7.2.1 TIMING ASSUMPTIONS

The current license is assumed to expire in 2034 for all the dams except for Calkins (license expires in 2040) and Webber (license expires in 2041). The current generation would continue until that year (inclusive). The relicense scenarios that assume upgrades or overhauls considers these to be performed immediately upon license issuance, followed by 50 years of operations under the new license. The studies and engineering required to relicense with upgrades and overhauls would be performed in the eight years prior to license expiration. On the other hand, decommissioning would occur after the expiration of the current license (technically with FERC’s approval to surrender), the duration of such decommissioning varies from 1 to 5 years depending on the scale of the decommissioning of each scenario. Studies and engineering required to surrender the license and decommission would be performed in the eight years prior to license expiration with FERC approval assumed in 2034 (2041 for Webber and 2042 for Calkins). All relicensing modeling assumed a similar evaluation process at the end of the next license period, therefore decommissioning costs were not included in any of the relicensing models.

7.2.1 RELICENSING COST ASSUMPTIONS

For relicensing scenarios, Capital Expenditures (CapEx) costs are associated with two types of spend: (1) upgrading the units; or (2) overhaul the units. CapEx costs that upgrade or overhaul units increase generation and resulting revenues. Table 4 presents the Capital Cost of turbine upgrades or overhaul associated with the relicensing options. Appendix A-1, WSP Review of Turbine Upgrade and Overhaul Costs details the input items for these two scenarios. These turbine capital costs are added to the Strategy Projection costs for major civil works such as Spillway repairs. WSP reviewed and utilized Consumers' project cost estimates from their current Strategy Projection (10-year projection) and included those projects that needed to be executed either for relicense or non-generation decommission (e.g., Spillway projects). Operational and maintenance (O&M) costs would also be incurred throughout a future license term and these costs were considered across the life cycle.

For relicensing scenarios, licensing costs begin before the current license expires and if the scenario has turbine upgrades or repairs those costs are incurred in the first couple of years before and after the subsequent license is issued to account for procurement, design services and installation. Future O&M and CapEx spend will be required to continue to operate and maintain the assets, so WSP developed assumptions on the spend for these activities and budgeted them into the model to occur in years 20, 25 (halfway of license anticipated major maintenance like generator rewinds, turbine repairs), 30, 40 and 50. Because the costs of these types of activities is known from planned spend for the first 10 years, a percentage of the overall spend was applied each year in future license years with a doubling of the percentage half way and a smaller percentage in year 50 to either relicense or surrender the license at that time.

Table 4. Turbine upgrade Costs for upgrade and Overhaul relicense options

.

7.2.2 SURRENDER COST ASSUMPTIONS

As previously described, WSP performed an independent analysis of the costs for the three defined surrender license scenarios. Preparation of the surrender applications and associated costs would be incurred before the current license expires. The surrender scenario of maintaining any reservoir behind a dam assumes the dam would meet state standards and costs to achieve this measure of safety are included in the first few years of the accepted surrender (e.g., spillway project). Spend associated with surrendering and decommissioning the sites are as follows:

1. Surrender 1 - No-Power Generation Operation: The existing water-dams would remain intact. The electric generating units and auxiliary equipment would be disabled to prevent generation of electricity. The dam and spillway would be modified to meet state dam safety requirements and maintain the reservoir. OpEx costs would be incurred to maintain the dam and spillway structure (e.g., dam safety standards, mowing, inspections).
2. Surrender 2 - Partial Removal: Demolition and removal of specific elements of the dam to lower the impoundment and re-establish the river channel through the project site. Only the embankment dam sections outside of the floodplain would be left intact. Exposed sediments and newly exposed shoreline would be stabilized and re-vegetated. OpEx costs would be incurred to maintain the remaining structures (e.g., six-foot weir, mowing, inspections).
3. Surrender 3 - Complete Removal: Demolition and removal of all the dam and powerhouse structures and reestablishment of the river channel through the former dam site. Includes full removal of the earth dam sections, concrete spillway, powerhouse, tailrace and retaining walls, and all appurtenant structures. During controlled drawdown, hydraulic dredging would be performed to approximate the river's original meander to allow the river to re-establish its course through the current reservoir. Contaminated sediments, if present, would be hauled off site and disposed of properly. No additional CapEx or OpEx costs would be incurred after the restoration is complete.

For the non-power operation and partial removal (both Surrender scenarios) a minimal O&M cost has been included to address maintenance responsibilities on the remaining portions of the dams (e.g., mowing, safety checks, monitoring). Operations and maintenance costs would not exist under the full decommission surrender scenario. Details of the assumed costs for surrender options are provided by site and by scenario in Appendix A-2, WSP Surrender and Decommission Costs.

7.2.3 REVENUE ASSUMPTIONS

Revenue is the financial benefit of generating electricity at the sites. Because Consumers is a regulated utility, revenues to the company are developed through the Michigan Public Service Commission planning process and include forecast costs and revenues from the entire portfolio of generation assets. As such, revenue estimates were provided by Consumers through 2049 that are assumed to include what the forecast costs and revenues from the future portfolio yields. Revenue rates in 2023 are $60.7/MWh and forecast to decrease over time to a value of $30.3/MWh in the year 2049 (see Figure 2). To estimate revenues for years Consumers did not provide estimates for, an average rate over the years 2045 to

2049 was used for the projection of the subsequent years in the analysis. Lastly, we assumed Consumers would be awarded a Department of Energy, Hydropower Grant of $2.5 million per site (spread evenly between 2025-2027) to help offset the costs of upgrades and dam safety projects. This figure represents half the maximum amount each site could be awarded as a conservative estimate that some sites may be awarded the full $5 million, and some sites won't be awarded anything. These grant revenues are assigned to each site under the relicense scenarios. Surrender and decommission scenarios would not generate revenue after the FERC Order approving license surrender; the timing of which is accounted for under Section *9.2.1 Timing Assumptions*. Consumers Energy reran the models with additional information on revenues related to capacity charges.

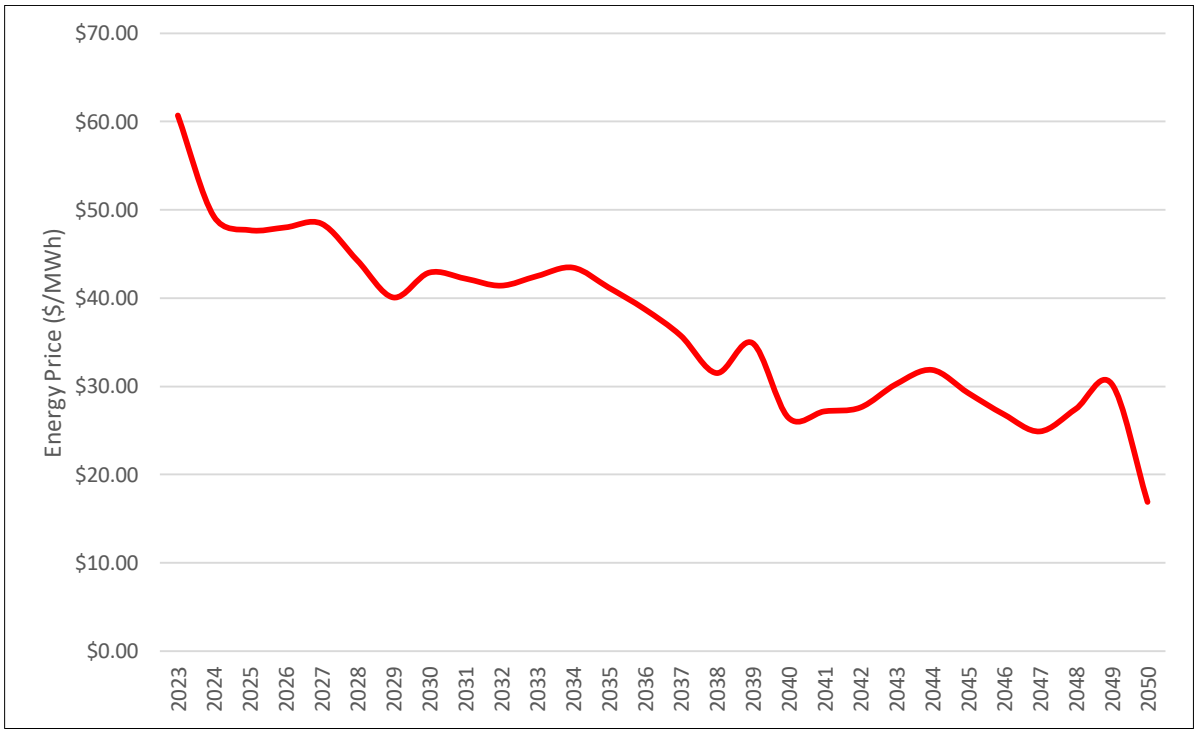

Figure 2. Energy Rate Forecast per MWh for the Consumers Hydro Portfolio

7.2.4 ESCALATION AND DISCOUNT RATES

CapEx and OpEx figures are expressed in 2022 base year dollars. CapEx figures have been escalated at 7% for values in 2023 to account for recent high inflation and at 4% more consistent with standard values for values in years 2024 to 2084. OpEx values are escalated at a slightly lower rate, 6% for values in 2023 because they include more labor than materials but still accounts for high inflation, and at 3% for values in years 2024 to 2084. The discount rate for NPV calculation is assumed as 7.5%; a generally accepted rate for similarly high-level financial planning as was modeled here. Consumers Energy reran the models with a slightly smaller escalation rate of 2% every year and added 40% to the CapEx costs to account for Consumer Energy overhead.

7.2.5 SENSITIVITY

To understand how sensitive the model was to CapEx or revenues, a simple sensitivity analysis of each model run was performed adjusting these two inputs. The sensitivity analysis responded to the question *"What would be an energy rate that would make the investments break even?"* The sensitivity analysis generated 390 possible energy rates and the sensitivity was limited to the relicensing scenarios only. The two adjustments related to revenue (energy rate) were: (1) energy rate would be fixed throughout the period of analysis starting in 2023, or (2) that it would increase annually at 1 percent, 2 percent, 3 percent, or 4 percent. A separate sensitivity in the model was developed to investigate how rates would respond if the CapEx spend was 50 percent the base estimate. Figure 3 shows the sensitivity model runs for the upgrade and maintain/ repair scenarios.

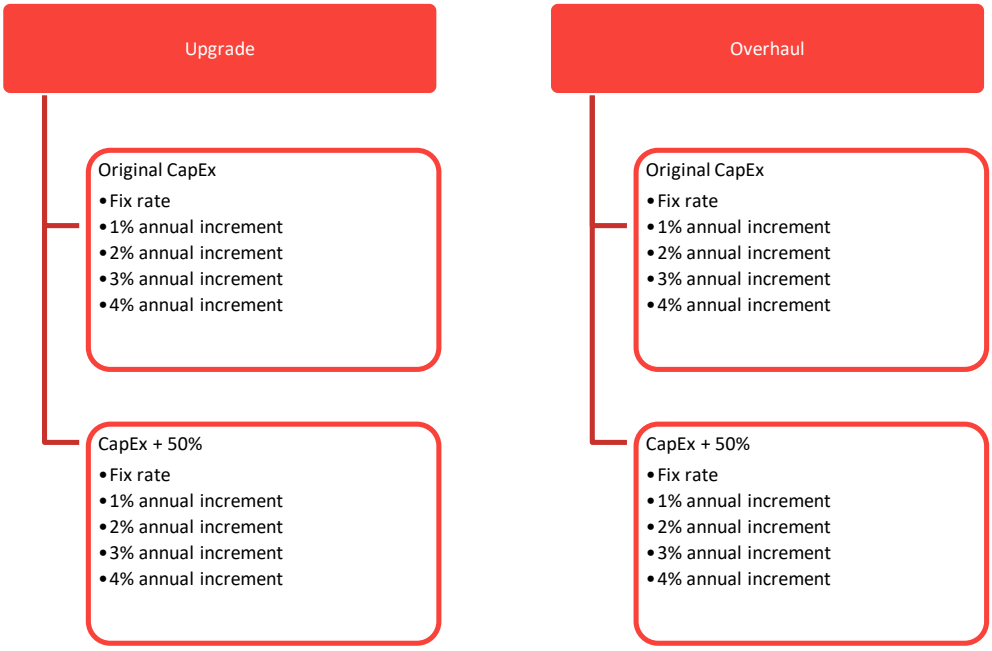

Figure 3. Sensitivity Model Runs

8 RESULTS AND INTERPRETATION

8.1 BASE CASES

The result of the financial model is a comparative cashflow of estimated costs and revenues, and a Net Present Value (NPV) or Net Present Cost, of such cashflow over the analysis period. Negative NPV means there is no value creation with the investments and positive NPV means these investments result in a positive return during the analyzed 50-year term. Table 5 summarizes the NPV of each scenario for each site.

8.1.1 SENSITIVITY RESULTS

As explained above, the sensitivity analysis performed is a numerical exercise that serves the purpose of conveying the importance of certain model/analysis inputs on the outcome. In this case, it provides a comparison of the costs of proposed investments during a future license, even though the energy rate cannot be increased freely as such, and its price setting is far more complex and regulated. This analysis is done by considering an energy rate for 2023 that is either escalated or fixed during the 50 years a future license and studying what the revenue rate should be for a break-even scenario with the defined capital project costs and under incremented capital projects costs. The sensitivity analysis results are presented in the next subsections.

8.1.1.1 BREAK EVEN ANALYSIS UNDER CURRENT ENERGY RATE

According to the results of the sensitivity analysis, there is a single scenario that result in an energy rate that is under the current price of $60.7/MWh suggesting its possible for a site to be financially neutral or better if the energy rate does not decrease in the future and even if the Capital costs of Overhauling or Upgrading increase by 50%. Table 6 illustrate the project that could break even under the hypothesis of no decline on the revenue side and show the corresponding 2023 energy rate and subsequent years escalation factor.

Table 7. Positive NPV Scenarios

Type of investment	Site	Energy rate Escalation beyond 2023	2023 Rate for NPV = 0 ($/MWh)
Relicense 1 – Upgrade			
Relicense 1 - Upgrade	Hodenpyl	4%	$ 59

8.1.2 SENSITIVITY - CONSERVATIVE

8.1.2.1 CAPEX IS ACCURATE AND NO ESCALATION IN REVENUE

This sensitivity analysis considers no increase in CapEx and no escalation in revenue. The result shows that energy rates would have to be much higher than current rates for the NPV to break even. Table 7 and figure 4 show the rate at which the sites result in a NPV that breaks even. This analysis shows that, to generate the revenues to offset the CapEx spend, revenues (rates) must start much higher than current conditions. This is due to the amount of CapEx spend necessary to upgrade and maintain these assets relative to the amount of generation (and ultimately revenues) they have the capacity to produce.

Table 8. Fixed Energy Rates to Break Even

9 RISK ANALYSIS

9.1 MUSKEGON RIVER SYSTEM

9.1.1 ROGERS RISK SUMMARY

Rogers limited generation capacity relative to the estimated costs to achieve dam safety compliance or upgrade or repair the units results in larger negative NPV for relicensing and surrender-non generation alternatives (scenarios where dam remains in place) compared to the surrender full and partial decommission alternatives. This is a function of the CapEx spend without sufficiently large enough capacity to generate revenues to offset those costs. Additionally, although Rogers does meet state water quality standards for temperature, the reservoir does contribute to warming as the reservoir provides thermal mass minimizing potential for cooling at night contributing warmer waters downstream where the temperatures downstream of Croton fail to meet the standards. Divesting Rogers may make the most sense if balancing costs with reputation to appease the private property owners. Table 10 summarizes the issues for Rogers that influence the opinion of best outcome to pursue as part of this roadmap and Table 11 summarizes the risks by risk category.

Table 11. Rogers Issue Matrix Summary

Attribute	Considerations
Environment	Although Rogers reservoirs and releases do meet state water quality standards for temperature, Rogers does contribute to warming temperatures downstream at Hardy and Croton (yellow) by preloading temperatures into the waters entering those Projects. Operational compliance concerns related to run-of-river reregulation between Rogers and Croton requires gauging and automation (yellow). Surrender removal eliminates thermal loading on the river system and opens upstream habitat for fish allowing more habitat for natural reproduction (green).
Dam Safety	Relicensing requires spillway upgrades which are currently out of compliance (red). Surrender with dam in place potentially lowers dam safety regulations that need to be met (from FERC to state standards). This (orange). Surrender removal and divest eliminates the risk (green).
Economics	NPV ranges from -$145M to -$62M with relicensing more expensive due to spillway capital projects (regulatory compliance). Surrender-partial decommission is the lowest NPV. All scenarios result in negative NPV (red). Divest option could provide economic benefits (orange).

Attribute	Considerations
People	Relicensing with new equipment better for staff than maintaining and repairing (yellow). Full dam removal eliminates safety hazards to staff and public (green).
Reputational	400+ private parcels[3] around reservoir that could be directly impacted by Consumers decision; relicensing or surrender with dam in place would be status quo for these entities (green). Surrender – partial or full decommissioning would elicit public outcry but agency agreement (red).

Table 12. Rogers Risk Matrix

RISKS					
Rogers	**Environment**	**Dam Safety**	**Economics**	**People**	**Reputation**
Relicense - Upgrade Units			-$ 141M		
Relicense - Overhaul (refurbish units in kind)			-$ 145M		
Surrender - No-Power Generation			-$ 113M		
Surrender - Partial Decommission			-$ 62M		
Surrender - Full Decommission			-$ 65M		
Divest					

9.1.2 HARDY SITE SUMMARY

Hardy has significant dam safety requirements associated with an aging and undersized spillway that need to be addressed within the current FERC license and is likely a significant contributor to driving the interest in this roadmap. Although Hardy is a popular reservoir for recreation there does not appear to be a realistic path forward that eliminates all the risk associated with operating the Hardy Dam in the future without addressing the issues related to the spillway. Given the high number of recreation resources around Hardy, the partial and full decommission alternatives would generate the most risk to Consumers reputation with the community. However, as great as the cost of decommissioning the dam and the risk to Consumers reputation is, the NPV of -$196M is better than rebuilding the spillway and leaving the dam in place with NPV of -$264M. It is our opinion that the best path forward to reduce future risks to Consumers

[3] All references to parcels associated with projects are preliminary and for more accurate information one should reference the Consumer contribution studies.

is a full decommissioning. Table 12 summarizes the issues for Hardy that influence the opinion of best outcome to pursue as part of this roadmap and Table 13 summarizes the risks by risk category.

Table 13. Hardy Issue Matrix Summary

Attribute	Considerations
Environment	Hardy powerhouse is on the SHPO list of historic places and the reservoirs depth contributes cool temperatures downstream to Croton. Peaking operations likely to receive pressure to change during relicensing (orange). Surrendering and partial removal could improve water temperature issues downstream of Croton while maintaining the powerhouse for SHPO purposes (yellow). Full removal would improve environmental conditions but require mitigation for the powerhouse listing on historic places (yellow).
Dam Safety	Auxiliary Spillway capacity is in need of repair and undersized to pass the PMF per new FERC regulations (red). Surrendering the license with the dam in place may provide a pathway for the dam falling under state rules which the spillway currently meets; however, meeting a different regulatory body doesn't lessen the risk and the 2018 inspection report rated the spillway as needing replacement in 3-5 years (red). Surrender – full or partial decommission eliminates this risk (green)
Economics	NPV ranges from -$310M to -$304M with spillway capital project (regulatory compliance); the significant driver for relicensing and surrender non-generation scenarios. Surrender partial and full decommission are less costly ranging from -$264 to -$186M (red). Divest likely not an option for Hardy given the expensive spillway CapEx spend requirement unless a future owner thinks they can achieve compliance with an alternative means.
People	Relicensing with new equipment better for staff than operating and maintaining (yellow). Full dam removal eliminates safety hazards to staff and public (green).
Reputation	Hardy provides substantial recreation with five major parks, 14 commercial marinas, HOAs, and private access docks. Relicensing or surrendering the dam in place would be status quo for these entities (green). Dam removal or partial removal would elicit public outcry but expect some agency support (red).

Divest					

9.1.3 CROTON SITE SUMMARY

Croton does not have spillway constraints requiring extensive capital expenses to remedy; however, it does exhibit water temperatures outside the state criteria; fails to pass fish upstream and utilizes 100-plus year-old equipment that would require maintenance. Given the adequate spillway at Croton, the dam's ability to block the invasive sea lamprey, and the high density of private and commercial properties surrounding the reservoir pursuing a relicense option or the surrender with dam in place option all have qualitatively equal outcomes from a risk perspective. The lowest NPV option would be to surrender and not generate. Table 14 summarizes the issues for Rogers that influence the opinion of best outcome to pursue as part of this roadmap and Table 15 summarizes the risks by risk category.

Table 15. Croton Issue Matrix Summary

Attribute	Considerations
Environment	Barrier to upstream fish passage (and potentially self-sustaining populations), failure to meet water temperature criteria, reregulating reservoir, 2nd most popular fishery in state downstream of Croton (orange for alternatives that dam remains in place); however, sea lamprey barrier remains in place. Under dam removal alternatives sea lamprey exclusion would likely be required (yellow).
Dam Safety	Dam is in good shape for all alternatives (green) save for a partial decommissioning which slightly increases risks to workers and public (yellow)
Economics	NPV ranges from -$120M to -$18M with full decommissioning more expensive than relicensing but all scenarios result in negative NPV (red). Divest option could provide economic benefit (orange).
People	Relicensing with new equipment better for staff than operating until it breaks (yellow). Full dam removal eliminates safety hazards to staff and public (green)

Attribute	Considerations
Reputation	Nearly 80% of the Croton reservoir shoreline is privately owned and includes significant residential development, a campground owned and operated by Croton Township and numerous small commercial recreational enterprises

9.1.4 MUSKEGON RIVER SYSTEM OVERALL SUMMARY

Consumers Muskegon River system of hydropower projects, Rogers, Hardy and Croton represent 36 percent of the total capacity from the 13 river hydro's and are host to the highest number of private and commercial parcels and businesses. The section of the Muskegon is popular recreation destination with a mix of private and public lands as well as diverse flat water and riverine habitats for both natural and recreation resources. Operationally, the system allows peaking at Hardy with reregulation occurring at Croton to simulate run of river conditions downstream. From the dam safety and particularly from a CapEx perspective, spillway upgrades are required at Rogers and Hardy and early contractor involvement have put estimates in the multiple hundreds of millions of dollars to achieve regulatory compliance. These three hydropower projects have a well-established legacy within the Muskegon watershed and as the risk matrix shows above, the qualitative assessment suggests significant changes could be in the future for this watershed. Table 16 summarizes the issues by risk criteria for the entire Muskegon River system.

Table 17. Muskegon River System Issue Matrix Summary

Attribute	Considerations
Environment	The three reservoirs contribute to warming which negatively impacts the aquatic resources downstream of Hardy and Croton where temperatures exceed state criteria. Stocking as mitigation for this supports the popular fishery downstream of Croton Dam however Michigan DNR believes without the reservoirs the fishery could be self-sustaining.
Dam Safety	Rogers and Hardy are currently out of FERC compliance for their ability to safely pass the probable maximum flood. Preliminary analysis indicates large new spillways are necessary to achieve compliance at tremendous costs without having a positive effect on revenue. Croton Dam meets the regulations in place.
Economics	Relicensing would likely come with additional mitigation costs associated with updating recreation amenities and access, water quality mitigation, dam safety requirements and fish passage and sea lamprey prevention or control measures. Divest option could provide economic benefit for some of the sites.
People	Existing equipment is approximately 100 years old and requires tremendous maintenance and is labor intensive to keep operating putting operators at medium risk. Upgrading the equipment in the powerhouses could reduce these risks while surrendering the license would also reduce the risks. Partial dam removal maintains risk to recreational boaters near the low head dam and improves safety for staff; full dam removal eliminates risk
Reputation	Rogers has a less developed shoreline compared to Hardy and Croton; however, all three provide tremendous flat-water recreation opportunities. Maintaining the reservoir in place would allow businesses and users to continue current uses; however, the surrender and decommission options would significantly alter the types of recreation opportunities.

9.2 MANISTEE RIVER SYSTEM

9.2.1 HODENPYL SUMMARY

Hodenpyl has notable dam safety requirements associated with an original, auxiliary spillway, aging generating equipment, as well as water temperatures that exceed the state criteria and attempts to mix the lake have been unsuccessful. The USFS is a significant landowner around the reservoir and could be a tough negotiator during relicensing due to their mandatory conditioning authority. Similarly, surrender and decommission scenarios would require agreement with USFS on the level of restoration to the lands currently inundated and used for recreation. Integral to the dam is a retired fish ladder, which may or may

not be consistent with regulator preferences for this site. Table 17 summarizes the issues for Hodenpyl that influence the opinion of best outcome to pursue as part of this roadmap and Table 18 summarizes the risks by risk category.

Table 18. Hodenpyl Issue Matrix Summary

Attribute	Considerations
Environment	The relicensing and surrender no-power generation scenarios continue to exceed water temperature standards (orange) while the partial decommissioning option would lead to improvements (yellow). The full decommissioning provides improvements to water quality and fish passage/habitat (green).
Dam Safety	Several dam safety improvements are required including emergency spillway, downstream wall, core wall (orange).
Economics	NPV ranges from -$139M to -$83M with full decommissioning more expensive than relicensing. All scenarios result in negative NPV (red). Divest option could provide economic benefit (orange).
People	The relicensing and surrender no-power generation similar risk (yellow). Full decommissioning would result in improved safety to the staff and public resulting (green).
Reputation	Relicensing scenarios would maintain existing conditions to recreation and commercial access (green). Surrender partial and full decommission would result in public outcry from losing flat water recreation (yellow).

Table 19. Hodenpyl Risk Matrix

RISKS					
Hodenpyl	**Environment**	**Dam Safety**	**Economics**	**People**	**Reputation**
Relicense - Upgrade Units			-$ 83M		
Relicense - Overhaul (refurbish units in kind)			-$ 84M		
Surrender - No-Power Generation			-$ 59M		
Surrender - Partial Decommission			-$ 104M		
Surrender - Full Decommission			-$ 139M		
Divest					

9.2.2 TIPPY SITE SUMMARY

Tippy is the lower most dam on the Manistee River and simultaneously blocks invasive species and desirable fish passage upriver. Additionally, the facility contributes to water temperatures that exceed the state standards. The dam fails to possess a working fish ladder and removal of Tippy Dam would open dozens of miles of connected aquatic habitat in the Pine River which, according to Michigan Department of Natural Resources, would allow for self sustaining populations of anadromous fish; however, a small group of non-government organizations and agencies recognize a need for some small barrier to prevent sea lamprey from utilizing the same habitat. Tippy dam is also home to a population of endangered bats that roost in the spillway area which would make full decommissioning challenging. There are no notable dam safety issues. Tippy is the second largest by capacity within Consumers fleet of river hydros and the combination of low CapEx with steady revenue is a bonus for this Project. Because of this unique mix of issues at Tippy, exploring the divest option as part of a portfolio sale is warranted. If a buyer does not materialize, the presence of the endangered bats can help justify continuing to run the plant and maintain as necessary. Changes in revenue projections that increase over time would make investing in upgrading the units at Tippy more favorable. Table 19 summarizes the issues for Tippy that influence the opinion of best outcome to pursue as part of this roadmap and Table 20 summarizes the risks by risk category.

Table 20. Tippy Issue Matrix Summary

Attribute	Considerations
Environment	Relicensing continues to block fish passage and water quality criteria are exceeded (orange). Surrender non-generation and partial decommissioning would be similar to current conditions (orange). Full decommissioning as improvement to fish passage but negative impact on bats and loss of sea lamprey barrier (yellow).
Dam Safety	Dam in good condition with no notable dam safety concerns requiring attention under any of the scenarios (all green).
Economics	NPV ranges from -$120M to -$6M with surrender partial or full decommission the most expensive. The surrender non-generation has the smallest negative NPV -$6M. Divest option could provide economic benefit (orange).
People	Relicensing and Non-generation & partial decommissioning would have similar risks to employees and public (yellow). Full decommissioning rated would eliminate risks to employees and public (green).
Reputation	Relicensing scenarios would maintain the status quo and there wouldn't be any changes to recreation and commercial access (green). Surrender partial and full decommission options would generate the most public acrimony from losing flat water recreation (yellow).

Table 21. Tippy Risk Matrix

RISKS					
Tippy	**Environment**	**Dam Safety**	**Economics**	**People**	**Reputation**
Relicense - Upgrade Units			-$ 115M

Divest					

9.2.3 MANISTEE RIVER SYSTEM OVERALL SUMMARY

The Manistee River is one of Michigan's premier canoe float and finest steelhead, salmon and trout rivers due to its clear, cool water and natural woodlands. Operationally, Hodenpyl and Tippy provide 37,125 MW of capacity which represents 30 percent of the river hydro fleet capacity and with upgrades this could be higher. We anticipate considerable pressure from federal and state agencies to remove one or both of these dams during the upcoming relicensing to support aquatic resources and water quality. Based on the economic modeling surrender and decommissioning these dams would be the most expensive cost to Consumers (lowest NPV) suggesting there is an opportunity for divesting these assets or continuing to run them at the risk of enduring additional costs for mitigation in the subsequent license. Table 21 summarizes the qualitative risks to Consumers for the Manistee River Projects.

Table 22. Manistee River System Issue Matrix Summary

Attribute	Considerations
Environment	Relicensing would maintain the status quo and continue to fail to meet water temperature criteria, which results in fish stocking as mitigation, fish passage (and access to upstream habitats) would persist. Tippy Dam houses endangered bats and prevents upstream passage of sea lamprey. Under surrender scenarios water quality would improve, access to aquatic habitats would likely lead to self-sustaining populations and sea lamprey access prevention would have to be built into the mitigation outcomes.
Dam Safety	Under the relicensing scenarios Hodenpyl would require upgrades to comply with FERC regulations. Under removal scenarios dam safety risks would be eliminated

Attribute	Considerations
Economics	All scenarios result in negative NPV. Divest option could provide economic benefit.
People	Risks to people mostly yellow with improvement to green for the full decommissioning alternative
Reputation	Risks to reputation are lowest with maintaining the status quo and relicense the dams from the recreation and human dimension and would increase to yellow under the surrender options where the reservoirs are removed.

9.3 AU SABLE RIVER SYSTEM

9.3.1 MIO SITE SUMMARY

Mio is the most upstream project on the Au Sable River and receives potentially contaminated sediments from upstream sources, exhibits water temperatures higher than state criteria, and is located at the upstream section of federally designated wild and scenic river. To support biological and aesthetic qualities, the state has designated the Au Sable River as a Natural River from its headwaters downstream to Loud Dam (meaning its presence is inconsistent with the states comprehensive plan for the river). The U.S. Forest Service (USFS) is a significant landowner in and adjacent to the facility boundary with 4(e) condition authority which would require attention during relicensing likely resulting in recreation resource mitigation solutions (e.g., upgrades to access sites and campgrounds, fish stocking). The dam is also listed as a primary site for a removal by the state citing likelihood that fish populations could be self-sustaining without the elevated temperatures provided by the reservoir. Complicating the overall assessment for which outcome to pursue for Mio is that the powerhouse, dam and spillway are in generally good condition. Given Mio's location high in the watershed where there are lower flows available for generation, the 3.9 MW powerhouse represents three percent of Consumers' river hydropower portfolio capacity. Exploring a portfolio sale that includes Mio would be an easy path for relieving risk from Consumers as the plant is in good shape. Failure to consummate a sale with a buyer, surrendering the license and full removal of the dam would be the next recommendation and using removal as part of a broader relicensing strategy for the entire portfolio may help offset relicensing debts. Table 22 summarizes the issues for Mio that influence the opinion of best outcome to pursue as part of this roadmap and Table 23 summarizes the risks by risk category.

Table 23. Mio Issue Matrix Summary

Attribute	Considerations
Environment	Relicense and surrender non-generation options maintain existing water quality issues, ongoing fish stocking or install fish passage system. MDNR letters indicate the Au Sable River is known to have areas of groundwater contaminated with PFAS and upstream Wurtsmith Airforce Base is a superfund site (orange). Partial decommissioning scenario would improve water quality (yellow). Full decommissioning improves water quality, fish passage and stream habitat restored. Also removes barrier for downriver paddle trips into downstream wild and scenic river (green)
Dam Safety	Dam is in good shape for all alternatives (green) save for a partial decommissioning which slightly increases risks (yellow)
Economics	NPV ranges from -$64M to -$12M with full decommissioning more expensive than relicensing but all scenarios result in negative NPV (red). Divest option could provide economic benefit (orange).
People	Relicensing with new equipment better for staff than operating until it breaks (yellow). Full dam removal eliminates safety hazards to staff and public (green)
Reputation	Relicense options and no-power generation scenarios preserve the status quo without change to current recreational uses (green). Full decommissioning impacts public and private access along the reservoir (orange). Partial decommissioning reservoir would recede from current banks, but possible to maintain current recreational uses (yellow).

Table 24. Mio Risk Matrix

RISKS					
Mio	Environment	Dam Safety	Econ	People	Reputational

9.3.2 ALCONA SITE SUMMARY

Alcona exhibits similar water temperatures issues as Mio and is mitigated by fish stocking the reservoir. To support biological and aesthetic qualities, the state has designated the Au Sable River as a Natural River from its headwaters downstream to Loud Dam (meaning its presence is inconsistent with the states comprehensive plan for the river). The dam is located near artesian springs potentially compromising its structural integrity and dam safety issues (potential inability to pass the PMF) are cause for concern and require extensive capital expense. As such, continuing to own and operate Alcona through a subsequent license term would require substantial capital investments and commitments. It is our opinion that this facility should be packaged as part of a portfolio to divest. Failure to consummate a sale with a buyer, surrendering the license and full removal of the dam would be the next recommendation and using removal as part of a broader relicensing strategy for the entire portfolio may help offset relicensing debts. Tables 24 summarizes the issues for Alcona that influence the opinion of best outcome to pursue as part of this roadmap and Table 25 summarizes the risks by risk category.

Table 25. Alcona Issue Matrix Summary

Attribute	Considerations
Environment	Relicense options and no-power generation fail to address water quality (temperature) issues and continue fish stocking or install fish passage system (orange). Partial decommissioning water quality improved (yellow). Full decommissioning water quality compliant, fish passage and stream habitat restored (green).
Dam Safety	Ongoing RIDM, auxiliary spillway remediation for relicense and surrender non-generation scenarios (red). Partial decommission alleviates most of the risk from the structure (yellow). Full decommission eliminates dam safety risk (green).
Economics	NPV ranges from -$75 to -$51M with relicensing slightly more expensive than the surrender non-generation scenario. All scenarios result in negative NPV (red). Divest option could provide economic benefit (orange).
People	Relicensing with new equipment (yellow) better for staff than operating until it needs repairs (orange). Full dam removal eliminates safety hazards to staff and public (green)
Reputation	Relicense options and no-power generation scenarios preserve the status quo without change to current recreational uses (green). No-power

Attribute	Considerations
	generation alternative maintains existing dam but would require dam safety repairs (yellow). Full and partial decommissioning could impact county campgrounds with boat docks and potential need to regrade Bamfield Road and protect Bamfield Road Bridge (road closure) (orange).

Table 26. Alcona Risk Matrix

9.3.3 LOUD SITE SUMMARY

Loud provides peaking generation opportunities while recreation continues to be popular with anglers, downstream paddle trips and some flat-water fishing. Michigan DNR, Fisheries Report noted Loud Pond offers limited value for the fishery as an impoundment. Loud does not exhibit notable issues requiring extensive capital expense on the structures. The surrounding lands are owned by the USFS and Consumers and used for recreation. There are no private parcels associated with this project. Table 26 summarizes the issues for Loud that influence the opinion of best outcome to pursue as part of this roadmap and Table 27 summarizes the risks by risk category.

Table 27. Loud Issue Matrix Summary

Attribute	Considerations
Environment	Relicense options, and no-power generation scenario and partial decommissioning show negligible differences and would likely require continued fish stocking or install fish passage system (orange).

Attribute	Considerations
	Partial decommissioning would provide connected stream habitat for natural reproduction of fish (yellow) and full decommission would eliminate aesthetic issues of a partial removal (green).
Dam Safety	Dam is in fair shape for its age under all alternatives where dam would remain in place (relicense and surrender non-generation scenario (yellow). Full decommissioning which lowers this risk (green)
Economics	NPV ranges from -$65M to -$23M with partial and full decommission alternatives the most expensive however negligible difference between the two. Surrender non-generation alternative is the least deficit NPV. All scenarios result in negative NPV (red). Divest option could provide economic benefit (orange).
People	Relicensing with new equipment better for staff than operating until it breaks (yellow). Full dam removal eliminates safety hazards to staff and public (green)
Reputation	Full and partial decommissioning rated yellow: no private residence along shoreline but change in recreational use for Au Sable River camping sites, Loud Dam Campsite, Rollways Resort, and Westgate Scenic Overlook. Relicense options and divest rated green: no change to current recreational use of reservoir.

Table 28. Loud Risk Matrix

Surrender - Full Decommission			-$ 50M		
Divest					

9.3.4 FIVE CHANNELS SITE SUMMARY

Five Channels reservoir backs up to Loud tailwaters linking the two together operationally. Overall, recreation is focused on shoreline uses and angling with modest fishery qualities. Five Channels does not exhibit notable issues requiring extensive capital expense on the structures. The surrounding lands are owned by the USFS and Consumers and used for recreation. There are no private parcels associated with this project. Table 28 summarizes the issues for Five Channels that influence the opinion of best outcome to pursue as part of this roadmap and Table 29 summarizes the risks by risk category.

Table 29. Five Channels Issue Matrix Summary

Attribute	Considerations
Environment	All relicensing options considered ok under status quo (green). Partial decommission: no evidence of temperature stratification (yellow). Fish passage could be improved. Full Decommissioning rated green: fish passage improved.
Dam Safety	Dam is in good shape for its age under all alternatives (green) save for a partial decommissioning which slightly increases risks (yellow)
Economics	NPV ranges from -$53M to -$19M with partial and full decommission alternatives the most expensive. Surrender non-generation alternative is the lowest deficit NPV. All scenarios result in negative NPV (red). Divest option could provide economic benefit (orange).
People	Relicensing with new equipment better for staff than operating until it breaks (yellow). Full dam removal eliminates safety hazards to staff and public (green)
Reputation	Relicense options, no-power generation alt, and divest rated green: no change to current recreational use of reservoir. Full and partial decommissioning rated yellow: reservoir would recede from current shoreline, but not drastically since it currently functions as a wide stream; easier to maintain existing recreational features.

Table 30. Five Channels Risk Matrix

Surrender - Full Decommission			-$ 40M		
Divest					

9.3.5 COOKE SITE SUMMARY

Cooke reservoir receives stocking of walleye from MDNR, and fishery managers expect that removal of the dam would eliminate the need for stocking as the population could be self sustaining. Cooke does not exhibit notable issues requiring extensive capital expense on the structures. The surrounding lands are owned by the USFS and Consumers and used for recreation. There may be a single private parcel associated with this project. The dam is on the National Register of Historic Places. It is our opinion that this project should be packaged as part of a portfolio to divest. Table 30 summarizes the issues for Cooke that influence the opinion of best outcome to pursue as part of this roadmap and Table 31 summarizes the risks by risk category.

Table 31. Cooke Issue Matrix Summary

Attribute	Considerations
Environment	Relicensing with reservoir in place (orange), Surrender with reservoir or partial reservoir (yellow) and Full decommissioning improves water quality and fish habitats/passage improvements (green).
Dam Safety	Dam is in good shape for its age under all alternatives (green) save for a partial decommissioning which slightly increases risks (yellow)
Economics	NPV ranges from -$87M to -$21M with partial and full decommission alternatives the most expensive with full decommissioning the most expensive scenario between the two. Surrender non-generation alternative is the least negative NPV. All scenarios result in negative NPV (red). Divest option could provide economic benefit (orange).

Attribute	Considerations
People	Relicensing with new or overhauled equipment better for staff (yellow) than operating until it breaks (orange). Partial removal maintains risk to staff and public. Full dam removal eliminates safety hazards to staff and public (green)
Reputation	Relicensing and no-power generation alternative preserve status quo for recreation users. Full decommissioning rated red. Dam is on National Register of Historic Places. Impacts to Iargo Springs Recreation Area, Cooke Dam Public Access and Boat Launch, and Partial decommissioning rated orange: Some of the dam can be maintained for historic preservation purposes. Reservoir can partially be maintained for recreational use.

Surrender - Full Decommission			-$ 87M		
Divest					

9.3.6 FOOTE SITE SUMMARY

Foote is the lowermost dam on the Au Sable and experiences elevated water temperatures. Foote is also the only reservoir on the Au Sable that receives notable levels of motorized recreation. Because it is the most downstream dam it does block fish passage and invasive species from passing upriver. The tailwaters are popular salmon and steelhead fishery. The surrounding lands are owned by the USFS and Consumers and used for recreation with multiple parks and boat ramps. There is a subdivision and a homeowner association with community docks for its residents. Full removal would provide benefits to fishery management by removing a barrier to a large river while provide the most risk to the people and reputation of Consumers by drastically changing its use. It is our opinion that this project should be packaged as part of a portfolio to divest. Table 32 summarizes the issues for Foote that influence the opinion of best outcome to pursue as part of this roadmap and Table 33 summarizes the risks by risk category.

Table 33. Foote Issue Matrix Summary

Attribute	Considerations
Environment	Relicensing prevents fish passage of steelhead and salmon but does also prevent sea lamprey and is only reservoir on Au Sable with notable motorized reservoir recreation (orange), water quality continues to exceed state criteria. Full and partial decommissioning rated yellow for improvements to passage and water quality: Dam prevents invasive species (sea lamprey) further upriver. Water quality and fish passage improved.
Dam Safety	Dam is in fair shape for its age under all alternatives (yellow). Full removal and divest eliminate risks (green)
Economics	NPV ranges from -$100M to -$22M with partial and full decommission alternatives the most expensive scenario. Surrender non-generation alternative is the least negative NPV. All scenarios result in negative NPV (red). Divest option could provide economic benefit (orange).
People	Relicensing with new or overhauled equipment better for staff (yellow). Partial removal maintains risk to staff and public (orange). Full dam removal eliminates safety hazards to staff and public (green)
Reputation	Partial decommission would impact recreation access and parks (orange) Full decommissioning rated red: significant changes to recreational use (campsites and large number of cluster boat docks).

9.3.7 AU SABLE RIVER SYSTEM OVERALL SUMMARY

The Au Sable River is a world-famous trout stream and surrounded by Huron National Forest making it a popular recreation destination. Consumers owns about 3,500 acres near the six dams; much of which is leased to county and townships for parks, campgrounds, and boat rentals. Mio, Cooke and Five Channels are all listed on National Register of Historic Places. The Au Sable is a favorite with paddlers and the 23-mile stretch of river from Mio to Alcona is designated a National Scenic River. The lower watershed projects are located closer together providing more flatwater boating and fishing opportunities closer to Oscoda. As for dam safety, Consumers has been conducting a Risk Informed Decision Matrix process at Alcona as one of the first using this framework with FERC for almost 10 years to address Probable Maximum Flood. In addition, artesian springs near the dam may provide additional risks. Collectively, the dams have 41 MW of capacity; however, the units inside the powerhouses consist of original equipment installed about 100 years ago. Upgrading the units to modern, more efficient turbines would increase generation; however, under all scenarios investigated, each has a negative NPV due to the amount of costs required for improving the efficiency, addressing forecast CapEx spend, operations and maintenance and the forecast for revenues to decrease over time. Risks to Consumers staff across the Au Sable portfolio of projects is generally moderate due to the age of the equipment and pace of repairs to keep them operating. Consumers has a long history in the region with first bringing hydropower into the watershed and later through collaborative conservation and restoration practices of replanting the forests. The dams themselves provide access for recreation and fish stocking supports the recreational fishing. Collectively, the Au Sable River projects likely have value at market and divesting could be the best path for reducing risk and costs for Consumers. Table 34 summarizes the qualitative results for the Au Sable River.

Table 35. Au Sable River Issue Matrix Summary

Attribute	Considerations
Environment	Relicensing would maintain the status quo and upstream sites Mio and Alcona would continue to have issues meeting the state temperature standards which Consumers mitigates with fish stocking. This section of the river is also extremely popular for canoe and fishing and is a National Scenic River. Downstream reservoirs have different fishery and flat water based recreation demands. Foote dam provides the barrier so sea lamprey do not migrate and reproduce further upstream in the watershed. Surrender scenarios with dam decommissioning outcomes would improve water quality and aquatic habitats throughout the entire length of the river and would likely lead to self sustaining populations of fish. Sea lamprey access prevention would have to be built into these outcomes.
Dam Safety	Under the relicensing scenarios for the Au Sable River, Alcona would require upgrades to comply with FERC dam safety regulations resulting in the lowest ranking for this site; however, most of the other dams are in satisfactory condition based on condition assessments.

Attribute	Considerations
Economics	All scenarios result in negative NPV. Divest option could provide economic benefit.
People	Risks to people mostly associated with aging equipment and dam safety. Alcona is the only site on the Au Sable with notable dam safety concerns associated with the artesian springs and need to upgrade the spillway to pass the PMF. Scenarios with upgraded generation equipment or no dam at all pose the lowest risk to staff.
Reputation	Risks to reputation are lowest with maintaining the status quo and relicense the dams from the recreation and human dimension and would increase to yellow under the surrender options where the reservoirs are removed.

9.4 GRAND RIVER WEBBER DAM

9.4.1 WEBBER SITE SUMMARY

The Webber facility is a modest size hydroelectric operation with few serious safety hazards to consider as risks to Consumers. From the environmental perspective, fisheries and recreation are prominent drivers of future relicensing negotiations. The state operates the fishway at the site and it may soon become the most down stream barrier depending on the outcome of a structure in Grand Rapids. Salmon, steelhead, and smallmouth are popular with operational shutdowns occurring during spring salmonid smolt migrations. Future conditions may be developed to accommodate sturgeon in a similar way further limiting generation periods. The dam and downstream areas are popular angler access sites. The portage around the dam was raised as a concern by the MDNR and is likely to receive attention during relicensing. It is our opinion that Webber should be considered under the divest alternative. Table 35 summarizes the issues for Webber that influence the opinion of best outcome to pursue as part of this roadmap and Table 36 summarizes the risks by risk category.

Table 36. Webber Issue Matrix Summary

Attribute	Considerations
Environment	Relicensing dam and no-power generation option blocks fish passage but also sea lamprey, portage remains issue, and seasonal shutdowns to protect fishery (orange). Partial and full removal improve mixing and water quality as well as address important seasonal fish life stages; lamprey barrier lost (yellow). Divest eliminates risk (green).
Dam Safety	Dam is in good shape for its age under all alternatives (green) save for a partial decommissioning which slightly increases risks (yellow)

Attribute	Considerations
Economics	NPV ranges from -$48M to -$17M with partial and full decommission alternatives the most expensive with full decommissioning the most expensive scenarios between the two. Surrender non-generation alternative is the lowest NPV. All scenarios result in negative NPV (red). Divest option could provide economic benefit (orange).
People	Relicensing with new equipment better for staff than operating until it needs constant maintenance (orange). Full decommissioning eliminates safety hazards to staff and public (yellow)
Reputation	Partial decommissioning would potentially leave a six-foot weir/sea lamprey barrier in place posing a hazard to canoe/kayakers and significantly reducing the reservoir size (orange). All other scenarios forecast positive angles to Consumers reputation (green)

Table 37. Webber Issue Matrix

9.5 KALAMAZOO RIVER – ALLEGAN (CALKINS BRIDGE) DAM

9.5.1 CALKINS BRIDGE SITE SUMMARY

The popularity of Calkins Bridge reservoir for recreation and private and commercial property investment elevates the community concern and reputational considerations while exploring options for this site. Downstream tailrace fishing is extremely popular at the state-maintained fishing pier and access area. Complicating the decision process for roadmap outcomes is the presence of a Superfund site tied to historic paper mill activity on and along the Kalamazoo River upstream of Calkins Bridge dam with known

contaminated sediments settling into the upper reservoir. The dam itself is in suitable condition but all options that consider decommissioning must also consider its integration with the road and how that would impact removal costs. The site is the downstream structure blocking desirable fish passage and restricting undesirable invasive species. Table 37 summarizes the issues for Calkins Bridge that influence the opinion of best outcome to pursue as part of this roadmap and Table 38 summarizes the risks by risk category.

Table 38. Calkins Bridge Issue Matrix Summary

Attribute	Considerations
Environment	Relicensing and no-power generation options maintain status quo satisfying popular recreation while the dam presents barrier to upstream passage (yellow). Partial decommissioning improves fish passage while maintaining sea lamprey barrier but potentially mobilizes contaminated sediments in upper end of reservoir from upstream superfund site (orange). Full decommission improves fish passage, allows sea lamprey upstream, and potentially mobilizes sediments in upper reservoir (red)
Dam Safety	Dam is in good shape for its age under all alternatives (green) save for a partial decommissioning which slightly increases risks (yellow)
Economics	NPV ranges from -$127M to -$17M with partial and full decommission alternatives the most expensive with full decommissioning the most expensive scenario between the two. Surrender non-generation alternative is the lowest NPV. All scenarios result in negative NPV (red). Divest option could provide economic benefit (orange).
People	Relicensing with new equipment better for staff than operating until it breaks (yellow). Partial removal maintains risk to staff and public (orange). Full dam removal eliminates safety hazards to staff and public (green)
Reputation	Relicensing and no-power generation options no change for waterfront properties (green) Partial decommissioning rated orange: impact to waterfront properties Full decommissioning rated red: large impact to significant amount of waterfront properties

10 TIMELINE FOR ROADMAP SCENARIOS

All relicense and surrender scenarios are assumed to follow the same schedule between now and filing of the Notice of Intent (NOI) and Pre-Application Document (PAD) to FERC because they require FERC approval to achieve these outcomes. The Divest option is available now and in the future. The NOI and PAD are required to be filed between 5 and 5.5 years before the license expires to account for the licensing process (development of the application in consultation with stakeholders and agencies) and license processing from FERC before the license expires. This requires Consumers to file the NOI and PAD no sooner than January 1, 2029, and no later than July 1, 2029. e discuss the steps Consumers should take and the timing under the scenarios in the subsections below.

10.1 DIVEST

Prior to committing to relicensing or surrendering, Consumers can start taking actions immediately to market the hydropower portfolio to potential buyers. Consumers can meet with banks and brokers specializing in hydropower portfolios M&A, working with an owner's engineering representative to conduct an Independent Engineer review on the portfolio to advise on strategic opportunities or risks that potential buyers may try to leverage in negotiations, and prepare a digital data room for potential buyers to do their own due diligence. If buyer(s) are interested in the portfolio, Consumers could ask for bids, review terms of the offers, consider options, and negotiate a sale ahead of having to make a commitment to relicense or surrender. Considering the value of portfolios making the news in the last 5 years there is appetite for investment in hydropower assets. Consumers can pursue this scenario without compromising either the relicensing or surrender pathways. The option to divest an asset or the entire portfolio would also be available to Consumers after subsequent licenses have been received from FERC and really depends on Consumers' business model. Divesting does not have to include every Project; however, there is some strategic value in offering a mix of value within the portfolio.

10.2 RELICENSE

If committed to relicensing, Consumers can proceed with near term regulatory requirements while also maintaining a schedule to file the PAD and NOI on time and follow the FERC relicensing schedule. Within the relicensing process, Consumers would consult with agencies and stakeholders and have the potential to negotiate settlement agreement outlining terms for the next license including duration, mitigation measures and plans for maintaining the projects and amenities to meet license obligations. For projects that would receive upgrades or overhaul generating equipment, the licensing proposal would detail the increase in capacity (for upgrades) and timing of repairs into the license application for FERC approval. Implementing these upgrades in the first years of the license allows for longest amount of time to generate revenues at higher capacities and efficiencies.

Should Consumers seek consultants for strategic preparations before starting the licensing process, consultants could be hired a few years ahead of the NOI and PAD filing deadline. Given the voluminous

amount of information for each site and the timing of 11 of the 13 sites entering relicensing in the same year, hiring consultants early could be beneficial to both Consumers and the consultants to fully understand the resource issues, quality of available data, and options to prepare a unified strategy prior to documenting the resources in the PAD.

10.3 SURRENDER

If committed to surrendering the license, the process is similar as relicensing in that FERC and the agencies must approve the plan to surrender and address the existing structures. If a decision to surrender requires additional information, there is time for early study of environmental risks to refine the decommissioning plan and strategic approach to present during consultation. Opportunity exists to initially purse the surrender and decommission – no-power generation alterative and continue generating and collecting revenues until the consultation process matures and the surrender plan comes into focus. This strategy could allow the sites to operate for 5-20 years before a surrender plan is approved by FERC. Ultimately this strategy does have its place for a few sites like Tippy where the reservoir provides a benefit to the endangered bats overwintering in the spillway, but Consumers must also be prepared for a decommissioning and full removal alternative. By pursuing the surrender scenario and starting with the no-power generation alternative the requirement to remove the dams entirely would fall to the state agency's recommendations and conditions and FERC ultimately balancing the resources and making the final order on whether to accept the surrender.

Strategic timelines for each site were not investigated at this time. The next step for pursuing the surrender options at any site would be to conduct baseline environmental condition studies like bathymetry (to help estimate volumes of sediments), sediment characterization and contamination evaluation, restoration acreage estimates and develop internal plans and schedules. This process could occur in stepwise manner until sufficient information was available to develop a plan and schedule for the surrender and consult with stakeholders to refine the plan. Table 39 summarizes a high-level planning schedule for task durations for a hypothetical surrender.

Table 40. Planning Level Schedule for Surrender Process

Activity	Duration
Internal strategy and preparation	6-9 months
Prepare Initial Consultation Document	6-9 months
Convene Stakeholders	1-3 months
Propose Study Plans (e.g., bathymetry, sediment characterization, hydrology and hydraulics)	2-3 months
Consult with Stakeholders on Study plans	2 months
Revise Study Plans and Execute Field Work	1-2 seasons
Report Results – Consult with Stakeholders	3-12 months
Prepare Application to FERC	3-6 months
Respond to FERC AIRs	1-24 months
Prepare Detailed Design	Simultaneous with FERC Review
Permits, Approvals Needed to Start Construction	1-24 months post FERC Approval
Removal	12 months

11 CONCLUSION

Our analysis of the 13 river hydropower projects involved outlining and evaluating various future scenarios based on their condition, environmental risks, and dam safety risks. We used qualitative risk matrices and quantitative net present value (NPV) results to assess the scenarios at a high planning level. In addition to WSP economic model, Consumers Energy provided additional inputs for comparison with internal assumptions. While the costs used in our assumptions were approximate, they were consistent enough to provide equal measurements across all scenarios. Qualitative risks assessed with our analysis included the environment, dam safety, economy, people, and reputation. Although additional criteria weighting could have refined the results further, our level of detail was sufficient to inform our opinion regarding the current condition and level of risk for each scenario.

Table 40 summarizes the results of the WSP decision matrix and provides an opinion of best value outcome for every site that considers risk exposure and hydropower asset debts to Consumers. Our opinions take into account our estimates of future licensing negotiations, the age and costs required to operate and maintain the structures and generating units, necessary upgrades for operation and compliance with relicensing studies and negotiations, and NPV calculations based on high-level assumptions. Our opinion is based on our industry experience with relicensing, environmental compliance, and engineering of hydropower assets, and providing due diligence to buyers of hydropower portfolios. While our report does not consider the community impacts of the hydropower reservoirs on local businesses, residents, and primary and secondary economic inputs, we acknowledge that hydropower is an interdisciplinary energy generating asset. Overall, this opinion is formed with the available information within the timeline to deliver this report. While the assets have demonstrated strong performance over a century, their age and maintenance needs, coupled with evolving environmental regulations and safety standards and the CapEx required to maintain the status quo for generation has raised questions on the value of keeping them operational for another 50 years.

Table 41. Results of Decision Matrix

Site	WSP First Opinion	WSP Opinion Notes
Muskegon River		
Rogers	Surrender – Full Decommission	Scenario provides value across environment, dam safety, and people at the second lowest NPV. Initially this option would be negative to Consumers reputation from property owners and businesses that benefit from the reservoir.
Hardy	Surrender – Full Decommission	Scenario provides value across environment, dam safety, and people at the second lowest NPV. Initially this option would be negative to Consumers reputation from property owners and businesses that benefit from the reservoir. Its unlikely the project could be sold on the open market with the spillway not meeting PMF. The Surrender non-generation scenario would require

Site	WSP First Opinion	WSP Opinion Notes
		the spillway project making for an expensive alternative but could preserve reputation. Overhauling or upgrading the units do not generate sufficient revenues to offset spillway and upgrade or overhaul costs.
Croton	Divest or Surrender – Non-Power Generation	Divesting should be explored. Best alternative value based on risk matrix is the surrender non-power generation scenario and NPV. The surrender non-power generation option NPV is half the NPV for upgrading or overhauling the units (similar qualitative risk outcomes).
Manistee River		
Hodenpyl	Divest or Surrender – Full Decommissioning	Divesting should be explored as best option for Consumers. Best alternative value based on risk matrix is the surrender option full decommission as it would address environmental, dam safety and people risk; however, the option that fully reduces the risks to Consumers also has this has the highest negative NPV.
Tippy	Divest or Surrender – Partial Decommissioning	Divesting should be explored as best option for Consumers. Best alternative value from qualitative risk is not as clear as both surrender scenarios and both relicense scenarios have equal risk outcomes but in different ways. The NPV is smallest for the surrender – partial decommission scenario
Au Sable River		
Mio	Divest or Surrender – Full Decommissioning	Divesting should be explored as best option for Consumers. Best alternative value is the surrender option from a qualitative risk assessment; however, this has the highest negative NPV and it fully reduces risks to Consumers.
Alcona	Divest or Surrender – Full Decommissioning	Divesting should be explored as best option for Consumers. Best alternative value is the surrender option from a qualitative risk assessment; however, this

Site	WSP First Opinion	WSP Opinion Notes
		has the highest negative NPV and it fully reduces risks to Consumers.
Loud	Divest or Surrender – Full Decommissioning	Divesting should be explored as best option for Consumers. If not, the best from risk perspective is surrender full decommissioning. Full decommission provides highest qualitative rank at the highest NPV.
Five Channels	Divest or Surrender – Non-Power Generation	Divesting should be explored as best option for Consumers. Both relicensing alternatives and the surrender non-generation provide equal qualitative risk profiles. Best value in NPV is surrendering non-generation which shares similar risk profile as relicensing options.
Cooke	Divest or Relicense - Overhaul	Divesting should be explored as first option for Consumers. Both relicensing alternatives provide best qualitative risk value with overhaul having the smallest NPV; surrender full decommission has same qualitative risk as relicensing scenarios but larger negative NPV.
Foote	Divest or Surrender – Non-Power Generation	Divesting should be explored as best option for Consumers. Surrender non-power generation alternative provides best qualitative risk rank and lowest negative NPV. Foote dam's role in lamprey exclusion favors keeping the dam in place so the cost to generate electricity in the future yields negative relicensing NPVs due to costs to upgrade, overhaul and maintain the Project.
Grand River		
Allegan/Calkins Bridge	Divest or Surrender – Non-Power Generation	Divesting should be explored as best option for Consumers. Both relicensing alternatives and surrender non-generation provide equal qualitative risk values; however, relicensing scenario NPV more expensive than surrendering non-generation.
Kalamazoo River		

Site	WSP First Opinion	WSP Opinion Notes
Webber	Divest or Surrender – Full Decommission	Divesting should be explored as best option for Consumers. Surrender – full decommission provides highest value in qualitative risk to Consumers. Relicensing and surrender with dam in place show equal risks but less than full decommission. From NPV perspective, full decommission is largest negative NPV and surrender non-generation is the least negative NPV.

11.1 NEXT STEPS

Our work here is part road map and part decision tools to help support the decision process for each Project. We recognize and recommend that additional work be performed in the areas of the risk matrices and the economic model. Specific to the risk matrix, more work is recommended to tailor the matrix and use of it as a decision tool to Consumers' preferred risk appetite by weighting the attributes and developing a risk scoring scale to quantify and measure the outputs to differentiate between scenario outcomes. As the risk matrix is currently configured, risks are qualitatively measured with a color against the risk category with all categories weighed equally. This combination of (1) a lack of weighting, and (2) a lack of rubric to measure against, results in little differentiation between some of the scenarios or some scenarios with the same risk profile but in opposite outcomes (e.g., relicense and decommission could have same overall risk profile based on the scores for each attribute). Consumers could improve upon the current risk matrix tool by incorporating Consumers own business directives into the framework or creating a hierarchy among the attributes and how to consider the NPV model results.

Similarly, the economic model relies on a combination of budgeted costs and planning level cost estimates, general revenue inputs and assumptions on the amount and timing of CapEx and OpEx spend across the scenarios. Our team has little insight into the Public Service Commission's rate forecasts for revenues and relied upon the best information available, which was provided by Consumers which we believe to be based on business forecasts that factor in future generation scenarios based on the Consumer Integrated Resource Plan. Our economic model illustrates the relationship between CapEx and OpEx spend and revenue over time; however, because the revenue is forecast to decline, the CapEx and OpEx spend in the near term combine with the limited increase in capacity to generate substantial amounts of revenues, results in all scenarios having a negative NPV after 50 years. The application of these negative NPV across the scenarios could be further defined in combination with the risk matrices as it could be a weighted criteria or a casual consideration. What it can provide is a quantification and order of magnitude estimate relative to other dams to understand where value might be extracted from future investments relative to the amount of risks Consumers wishes to carry.

Additional items for consideration as far as next steps with the Road Map and Decision Tools:

11.1.1 DIVEST SCENARIO

- Prepare a Data Room
- Consider an owners engineer with experience in due diligence
- Consult experts in the banking and brokerage of hydropower assets
- Identify asset or portfolio of assets to sell
- Put portfolio on the market.

If Consumers business preferences are for relicensing or surrendering, the following items for consideration would help inform the decision to relicense or surrender:

Data that should be considered prior to making a relicensing or surrender decision:
Preliminary Investigation on:

- Preliminary investigation on sediment distribution, volumes and quality, etc. in reservoirs considered for decommissioning.
- Preliminary investigation on dams potential for listing with the National Register of Historic Places (cultural resource evaluations)
- Preliminary habitat modeling for estimating restoration area sizes, slopes, topography, and planting concept plans.
- Hydraulic/hydraulic assessments of current operations and for understanding potential future conditions (e.g., with partial and full decommission alternatives)
-

11.1.1.1 *STRATEGIC CONSIDERATIONS*

- Removal of any dam, whether partial or full decommissioning should proceed from upstream to downstream
- Preliminary strategy on the timing of a surrender filing that balances generation with studies and potential off takers for the surrender non-generation scenario

A ECONOMIC MODEL

APPENDIX

A-1 WSP REVIEW OF TURBINE UPGRADE AND OVERHAUL COSTS

Appendix A

APPENDIX A-1

WSP INDEPENDENT REVIEW OF COSTS TO UPGRADE AND OVERHAUL TURBINE EQUIPMENT

Investments can be made to improve the efficiency of existing generating units through overhauls, generator rewinds, or turbine replacements. In particular, as plants reach the license renewal period, upgrades to existing facilities to increase capacity or energy output are typically considered. Consumers produced an internally prepared planning estimate of upgrading or overhauling their generating units and estimated the resultant increase in generation. WSP reviewed existing information related to the current equipment, plant efficiency, and annual generation and the potential upgrades or overhauls and compared the cost estimates with industry publications and our own professional experience in designing and overseing upgrades and overhauls at hydroelectric projects throughout North America.

UNDERSTANDING EXISTING CONDITIONS

Consumers' generation equipment is mostly original equipment constructed and put into operation about a hundred years ago. Because each hydropower project is designed specifically for the location of the dam, each plant has turbine-generator units designed specifically for the amount of flow and head a site provides. Additionally, operations were designed for the era they were installed. As the transmission grid expanded and electrical use throughout Consumers service territory evolved, so to did the environmental regulations and operating conditions. As such, the existing Francis units are designed for an operating regime that is outdated which results in generation below a sites potential. Initiating capital improvement projects that upgrade or overhaul the equipment would increase the output from the powerhouses.

UNDERSTANDING WORK INSIDE HYDRO POWERHOUSES - UPGRADES AND OVERHAULS

Upgrade is the removal of an incorrectly sized unit and replacement with a more efficient, modern unit that can generate more electricity, more regularly, across a wider range of flow conditions. An overhaul is considered the restoration of an existing unit (e.g., rewinding the generator, repair the runner and wicket gates, etc.) but rely on the original unit designs and equipment. Upgrades to turbines requires dismantling generators and bringing in new equipment. Installing new equipment would require investigation into access and current capabilities of such things as access (e.g., road, entry doors) or equipment needs (e.g., overhead crane upgrades). A larger crane may require structural analysis of the load bearing portions of the structure (e.g., walls, foundation). The higher efficiency units may occupy larger spaces in

the powerhouse so changes to the structures (expanding concrete and repouring to accommodate new equipment) could also be required. Similarly, upgrades to the generators could require changes to the electrical equipment in the powerhouse as well as transmission to the substations. Lastly, getting equipment out of the powerhouse and new equipment in may require upgrades to the access roads or even the openings to the powerhouses depending on the size of the new equipment; which given the age of the powerhouse could require consultation with Michigan SHPO and potential mitigation measures. The value of this work would be increased generation and resulting revenues. These upgrades would not address dam safety or alter flows, change temperature patterns or address fish passage as these types of projects are limited to inside the powerhouse. Table A-1 summarizes the types of equipment inside a hydro powerhouse and the potential number of components that could be upgraded or overhauled. Each upgrade or overhaul at a particular powerhouse needs to be planned specifically for the site conditions of that powerhouse including access, civil, structural, electro-mechanical equipment, and electrical tranmission. Upgrades to portions of the equipment may require updates to other components of the system to ensure the safest and most reliable use of the upgraded or overhauled equipment.

Table A-1. Key Components of a Hydroelectric Project Upgrade or Overhaul

INDUSTRY STANDARDS – LITERATURE REVIEW

To verify the Consumers cost estimates reasonableness we performed a literature review to compare published costs of overhaul hydropower plants. The results of the literature review were escalated into the same year as Consumers data and evaluated for the precision to ultimately evaluate if the costs were reliable and appropriate for use in our economic model. The following sections discuss the data sources and steps in this process.

Department of Energy – National Renewable Energy Lab Report

The U.S. Department of Energy published reports on hydropower costs relative to potential increases in hydropower throughout the U.S. including costs to add hydropower to existing dams, new construction of hydropower plants, as well as utiliizing existing canals or conduits. Based on the United States-only subset of the collected data, the cost of constructing a hydropower plant on existing conduits, on non-powered dams, or along new, undeveloped stream reaches has ranged from $1000 to $9000 per kilowatt (O'Conner 2015).

In addition to the construction of power generating facilities on previously unpowered infrastructure or stream reaches, costs estimates were also collected for the installation of additional units in existing powerhouses and the rewinding of existing generators; the average addition of a new unit to an existing powerhouse has cost $1,930 per kilowatt, and the average generator rewind has cost $114 per kilowatt, but both are subject to strong economies of scale based on the size of the units involved (O'Conner 2015).

National Hydropower Association (Navigant Study 2009)

In early 2009, the National Hydropower Association (NHA) commissioned Navigant Consulting to conduct a study examining the hydropower industry's job-creation and capacity-growth potential. In assessing the potential for new generating capacity, the study looked at several major classes of hydropower technology and project costs to install the technology. Table A-2 summarizes the installed costs compiled by NHA.

Table A-2. Installed Project Costs for Various Types and Sizes of Hydro Projects (NHA 2023)

Hydropower Technology	MW Range	Installed Cost ($/kW)	Discussion
Conventional Hydro (impoundment)	50 (average)	$1,000-$5,000	A mature technology, conventional hydro falls at the lower end of the range of installed costs, particularly for upgrade projects at existing sites. New dams and greenfield sites are more expensive.
Microhydro	< 0.1	$4,000-$6,000	The installed cost for low-impact hydro systems is not expected to decline in the near term.
Run of River (diversion).	Approx. 10	$1,500-$6,000	Similar to conventional hydro, installed costs for run-of-river can vary widely.

Appendix A

Hydropower Technology	MW Range	Installed Cost ($/kW)	Discussion
Pumped Storage	>500	$1,010-$4,500	Traditional pumped storage is a proven technology and costs are not expected to decline going forward. The new underground pumped storage technology has been quoted at $2,000/kW and cost declines can be expected going forward, if the concept proves itself.

Source: https://www.hydro.org/waterpower/why-hydro/job-creation/navigant-study/ as viewed on NHA website. The Navigant Study is from 2009

ESCALATION OF COSTS

Both the DOE and NHA cost estimates for upgrades and overhauls are more than 10 years old. Although the technology doesn't change the price of materials and services to execute these types of projects does. A number of organizations help industry by tracking prices over time and developing escalation tools so project planners and managers can understand prices from the past in today's dollars. Indices for escalations are based on actual historical data.

Engineering News-Record (ENR) publishes monthly construction cost indices for 20 cities in the U.S. Recent ENR construction cost indices for 2022 showed 14.7% annual increase and for materials a 31.6% annully and cost of steel up over 39% in the same period which provides evidence that even in the last few years project costs have increased substantially. The U.S. Army Corps of Engineers (USACE 2021) prepared the Civil Works Construction Cost Index System (CWCCIS); an escalation calculator to provide historical and forecasted cost indices for use in escalation USACE civil works project costs. Although the tool was developed for the USACE, the USACE is the largest federal provider of hydropower in the U.S. and has access to a large dataset related to hydropower powerhouse costs and is therefore a reasonable dataset to escalate. This escalation tool was used to bring cost information summarized in the literature into current dollars.

LEVELS OF GRANULARITY IN COSTS – ENGINEERING ESTIMATING LEVELS

Although hydropower costs are highly site-specific with many factors contributing to cost uncertainty, cost accuracy is generally assumed to increase as project development nears completion. As such, construction stage cost estimates are necessarily considered the most accurate [and are quantitatively defined as such by Association for the Advancement of Cost Engineering (AACE)].

Construction Cost Estimate Classes

CLASS 5

This is known as the rough order of magnitude (ROM) estimate. It is used for the initial screening projects for capital expenditure planning. Since several projects are initially available, estimating each would

require a tremendous amount of time and effort. Given the limited preparation, ballpark figures are usually accepted to make business plan projections. Class 5 estimates are drawn from limited information which is about 0 to 2% of the project definition. The information may be nothing more than a basic description of the plant or process, capacity, and location. That is why its **accuracy ranges -50% on the low side and +100% on the high side**.

Class 5 cost estimate accuracy range: -50% to +100%
Stochastic cost estimating methods are used for obtaining a Class 5 estimate. Examples of these are cost/capacity curves, rule of six-tenths, Lang factor method, scale of operation factors, and cost indices. These techniques use parametric cost estimation methods to deduce the total cost of a given project.

CLASS 4

A Class 4 estimate is considered a feasibility study estimate. It is used by organization heads and construction managers for strategic business planning. A more detailed approach is required since this would determine the viability of the project. Moreover, alternative project schemes are evaluated for their economic value. Feasibility studies for industrial constructions often require the definition of roughly around 1% to 15% of the project. Aside from basic descriptions, other inputs that influence project costs include:

- Process flow diagrams (PFDs)
- Major construction activities
- Equipment lists

Class 4 is more detailed than what we have for our economic model at this stage of model development.

WSP ECONOMIC MODEL

WSP investigated upgrade and overhaul calculations prepared by Consumers for its reasonableness, increase in generation, and project costs. Because these are Level 5 planning estimates the constructed costs for upgrades or overhauls can vary widely.

Table A-3 summarizes Consumers powerhouse capacities and potential increases in power under upgrade or overhaul scenarios with an escalated cost per megawatt metric. Tables A-4 summarize WSP costs to upgrade units while Table A-5 summarize the upgrade costs for Consumers and WSP used in the report.

Appendix A

Table A-3. Consumers Estimates for Upgrades and Overhauls

Site	Consumers Estimated Cost for Upgrade 2019 ($)	Consumers Estimated Cost for Overhaul 2019 ($)	Turbine Upgrade Cost in 2022 $ (2019 Cost Multiplied by Escalation Factor of 1.31884 per USCOI)	Turbine Overhaul Cost in 2022 $ (2019 Cost Multiplied by Escalation Factor of 1.31884 per USCOI)
Rogers	$17,185,500	$17,928,000	$22,665,000	$23,644,000
Hardy	-	-	-	-
Croton	$35,289,000	$25,446,600	$46,541,000	$33,560,000
Hodenpyl	$22,573,800	$21,735,000	$29,771,000	$28,665,000
Tippy	$32,703,750	$30,510,000	$43,131,000	$40,238,000
Mio	$13,948,924	$15,603,750	$18,396,000	$20,579,000
Alcona	$18,312,871	$18,765,000	$24,152,000	$24,748,000
Loud	$21,373,200	$14,310,000	$28,188,000	$18,873,000
Five Channels	$21,508,200	$18,427,500	$28,366,000	$24,303,000
Cooke	$24,772,500	$19,016,100	$32,671,000	$25,079,000
Foote	$22,882,500	$25,922,250	$30,178,000	$34,187,000
Allegan (Calkins Bridge)	$9,929,250	$8,775,000	$13,095,000	$11,573,000
Webber	-	-	-	-

Note: Consumers did not prepare an evaluation of cost to upgrade or repair Hardy or Webber.

Appendix A

Table A-4. WSP Estimated Upgrade Costs

Site	Current nameplate capacity (MW)	Potential capacity after upgrade (MW)	Head (FT)	Turbine Cost in 2002 $	Turbine Cost in 2022 $ without OH[1]	Turbine Cost in 2022 $ Plus OH[2]	NOTES
Rogers	6.75	10.4	41.5	$7,727,562	$16,868,000	$22,772,000	2.6 MW Kaplan Turbine Units 1 through 4
Hardy	31.5	34.7	100.2	$12,131,389	$26,481,000	$35,748,000	Potential capacity increased was assumed to be 10%. Assumed upgrade would be from Francis to Kaplan
Croton	8.85	19.6	41.7	$14,238,365	$31,080,000	$41,958,000	Adding Kaplan unit to the Dead Bay and Units 1 and 2 have 2 Kaplans each because they each have 2 draft tubes.
Hodenpyl	17	23.3	71.6	$7,914,708	$17,277,000	$23,324,000	Upgrade to Unit 1 Kaplan unit and Unit 2 is the existing unit with upgraded 6.25 MW smaller Francis runner.
Tippy	20.1	39	47.4	$17,555,964	$38,322,000	$51,735,000	Units 1, 2, and 3 are 13 MW Kaplans
Mio	5	7.0	29.7	$5,434,649	$11,862,000	$16,014,000	3.5 MW Kaplan Turbines Units 1 and 2
Alcona	8	14.0	44.1	$7,703,249	$16,814,000	$22,698,000	7 MW Kaplan Turbine Units 1 & 2
Loud	4	4.8	27.5	$4,264,770	$9,310,000	$12,568,000	Assumed upgrade to Seagull Units 1 & 2. No Seagull unit assumptions in literature, Used Kaplan coefficients as an assumption

Appendix A

Site	Current nameplate capacity (MW)	Potential capacity after upgrade (MW)	Head (FT)	Turbine Cost in 2002 $	Turbine Cost in 2022 $ without OH[1]	Turbine Cost in 2022 $ Plus OH[2]	NOTES
Five Channels	6	7.0	35.8	$5,062,248	$11,050,000	$14,918,000	Assumed upgrade to Seagull Units 1 & 2. No Seagull unit assumptions in literature, Used Kaplan coefficients as an assumption
Cooke	9	10	39.4	$8,156,109	$17,805,000	$24,035,000	Replace Unit 1 and 2 with two dive turbines per bay and one dive turbine in the Unit 3 bay. Assumed Kaplan coefficients since no dive turbine coefficients.
Foote	9	15.9	44.9	$9,387,108	$20,491,000	$27,663,000	5.9 MW Kaplan in Unit 1, 5 MW Kaplans for Units 2 & 3
Allegan (Calkins Bridge)	2.55	2.5	16.0	$3,471,624	$7,578,000	$10,230,000	Unit 1 would be upgraded to a Kaplan and Units 2 and 3 would be overhauled. Overhaul costs not included in this table. Assumed Unit 1 increase of 10% but no total capacity increase value included as Units 2 and 3 increases are not provided.[3]
Webber	3.25	3.6	28.5	$3,403,032	$7,428,000	$10,028,000	Potential capacity increased was assumed to be 10%. Assumed upgrade would be from modified Francis and Propeller to 2 Kaplan units

Notes: [1] 2002 cost multiplied by escalation factor of 2.18284 per USCOI

[2] 2022 cost multiplied by 1.35 for 35% OH cost

[3] Allegan upgrade cost option included upgrading Unit 1 but overhauling Units 2 and 3. The equations used to calculate upgrade costs, in Table A-6, does not include unit overhaul costs. Thus, WSP assumed a 10% increase on Unit 1 (0.45 MW to 0.50 MW) for the upgrade and calculated the overhaul costs by taking a pro-rated overhaul cost (2.5 MW – 0.5 MW divided by 2.5 MW = 0.80, 0.80 multiplied by the $6,500,000 cost of the overhaul) and adding Unit 1 upgrade cost.

Table A-5. Summary of Consumers and WSP Turbine Upgrade Estimates

Site	Consumers Turbine Upgrade Cost in 2022 $	WSP Turbine Cost in 2022 $ Plus OH	Difference	Difference %
Rogers	$22,665,000	$22,772,000	-$107,000	-0.5%
Hardy	-	$35,748,000	-	-
Croton	$46,541,000	$41,958,000	$4,583,000	9.8%
Hodenpyl	$29,771,000	$23,324,000	$6,447,000	21.7%
Tippy	$43,131,000	$51,735,000	-$8,604,000	-19.9%
Mio	$18,396,000	$16,014,000	$2,382,000	12.9%
Alcona	$24,152,000	$22,698,000	$1,454,000	6.0%
Loud	$28,188,000	$12,568,000	$15,620,000	55.4%
Five Channels	$28,366,000	$14,918,000	$13,448,000	47.4%
Cooke	$32,671,000	$24,035,000	$8,636,000	26.4%
Foote	$30,178,000	$27,663,000	$2,515,000	8.3%
Allegan (Calkins Bridge)	$13,095,000	$10,230,000	$2,865,000	21.9%
Webber	-	$10,028,000	-	-

Table A-6. Cost Estimating Equations for Turbine and Generator Upgrades

Estimating Tool Application	Coefficient (A)	Exponent (B)	Exponent (C)
Francis Turbines*	3.E6	0.71	-0.42
Kaplan Turbines*	4.E6	0.72	-0.38
Bulb Turbines*	6.E6	0.86	-0.63
Generators**	3.E6	0.65	-0.38

*Turbines: Cost (2002$) = A x [Capacity (MW)]^{B} x [Head(ft)]^{C}
** Generators: Cost (2002$) = A x [Capacity (MW)]^{B} x [Speed(rpm)]^{C}

APPENDIX

A-2 WSP SURRENDER AND DECOMMISSION COSTS

Consumers Energy
Region Hydroplant
Decommissioning Cost Evaluation - Full Removal

Structure	Scope Item	Meade & Hunt Decommissioning Cost	Kiewit Decommissioning Cost	Unit	WSP Unit Cost	Quantity	WSP Opinion of Cost	WSP Notes
Impact Study	Environmental/Social Impact Study	$ 355,781	$ 340,000					Cost included in baseline studies, engineering & permitting.
Substation	Continued use of 46-kV substation	$ 59,039					$ 59,039	Utilize M&H Cost Opinion.
	Remove overhead lines between Powerhouse and MTR No. 1	$ 7,102					$ 7,102	Utilize M&H Cost Opinion.
	Wave distribution line from plant bus	$ 7,102	$ 140,000				$ 7,102	Utilize M&H Cost Opinion.
General Site	Remove security fencing	$ 4,719					$ 4,719	Utilize M&H Cost Opinion.
	Remove storage building	$ 94,462					$ 94,462	Utilize M&H Cost Opinion.
	Remove plant access road	$ 3,539					$ 3,539	Utilize M&H Cost Opinion.
	Remove septic tank / drain field	$ 11,809	$ 220,000				$ 11,809	Utilize M&H Cost Opinion.
	Survey site for environmental contamination	$ 2,362						Cost included in baseline studies, engineering & permitting.
	Remove pecorniers	$ 25,980					$ 25,980	Utilize M&H Cost Opinion.
Powerhouse	Leave powerhouse intact	$ -					$ -	
	Survey for contaminants	$ 2,362						Cost included in baseline studies, engineering & permitting.
	Remove or lay-up equipment	$ -					$ -	Utilize M&H Cost Opinion.
	Remove all powerhouse equipment	$ 191,694	$ 3,840,000				$ 191,694	Utilize M&H Cost Opinion.
	Demolish & remove powerhouse including intake/tailrace, retaining wall & apron	$ 805,328					$ 1,207,992	Utilize M&H Cost Opinion plus 50% contingency. Quantity verification needed to confirm M&H assumption.
Spillway	Modify spillway to maintain flow/pond level	-					$ -	
	Demolish and remove emergency spillway including concrete weir and apron	$ 2,148,262	$ 5,520,000				$ 2,148,262	Utilize M&H Cost Opinion.
Earth Dam and Reservoir/River Channel	Drain 449-acre reservoir	$ 957,351	$ 3,500,000				$ 957,351	Utilize M&H Cost Opinion. 30K CY riprap in erosion control measures line item utilized for temporary spillway protection.
	Demolish/remove portion of earth dam to create sufficient breach	-					$ -	
	Demolish/remove entire earth dam and core wall - excavation	$ 1,243,545		CY	$14.64	84,952	$ 1,243,545	Utilize M&H Cost Opinion.
	Demolish/remove entire earth dam and core wall - reinforced concrete demolition	$ 103,527		CY	$207.00	500	$ 103,527	Utilize M&H Cost Opinion.
	Demolish/remove entire earth dam and core wall - sheet piling removal	$ 33,032	$ 4,230,000	SF	$2.36	8,600	$ 33,032	Utilize M&H Cost Opinion.
	Remove accumulated non-contaminated sediments - Dam Pilot Channel	$ 1,815,509		CY	$11.81	136,800	$ 1,815,509	Utilize M&H Cost Opinion.
	Remove accumulated non-contaminated sediments - Reservoir Dredging	$ 16,716,595	$ 31,920,000	CY	$7.09	2,357,644	$ 16,715,696	Utilize M&H Cost Opinion for dredging of 200' wide channel.
	Remove accumulated non-contaminated sediments - Mob/Demob	$ 118,077		LS	$1.00	118,077	$ 118,077	Utilize M&H Cost Opinion.
	Remove contaminated Sediments - Removal		$ 9,530,000	CY	$7.09	54,143	$ 383,871	Assume 10% of reservoir requires dredging at average depth of 12" prior to drawdown to remove contaminated sediment. Dependent on sediment characterization.
	Remove contaminated Sediments - Disposal		$ 75,000,000	ton	$70.00	108,285	$ 7,579,951	Disposal of contaminated sediment
	Seal former reservoir bottom	$ 625,976	$ 1,000,000					Revised cost included below.
	Habitat Restoration - Reservoir	$ -	$ 320,000					Revised cost included below.
	Apply erosion control measures - silt fence	$ 17,138		LF	$5.00	18,000	$ 90,000	Utilize M&H quantity. Adjust unit price based on similar projects.
	Apply erosion control measures - erosion mat	$ 40,929	$ 2,700,000	SF	$0.24			Cost not included. Assume jute mat on banks and straw & tackifier during seeding that is included in other items.
	Apply erosion control measures - riprap protection	$ 1,769,586		CY	$150.00	5,000	$ 750,000	Increase riprap protection costs for temporary diversion to $150/CY. Assume 5000 CY for temporary protection. Additional riprap captured in Bank Stabilization - Hard Structure & Channel Creation - Riffle Section items.
	Reuse (seeding) of non-contaminated excavated & dredged material			CY	$8.00	2,442,596	$ 19,540,768	Additional effort to grade/rework material excavated/dredged for specific habitat creation.
	Bank Stabilization - Hard Structure			LF	$333.33	4,908	$ 1,635,984	Main channel = 16,360 LF. Other Tributary tie in = 3,430 LF; assume 15% hard structure banks for only main channel banks
	Bank Stabilization - Live Stakes & Jute Mat			LF	$54.53	34,872	$ 1,890,664	Main channel = 16,360 LF. Other Tributary tie in = 3,430 LF; assume 85% for main channel banks, assume all other banks
	Habitat Restoration - Seeding			Acre	$3,100.00	262	$ 813,720	Acreage outside of dredged channel, assume 300' width for main river channel, 50' width for tributary connections, include footprint of earthen dam and spillway.
	Habitat Restoration - Planting			Acre	$3,072.00	131	$ 403,185	Assume 50% of seeded area is planted, assume 10' OC spacing, 480 plants per acre, #2 container 1-2' high, $6.40/plant; assume 50% of acreage is planted
	Channel creation - Riffle Section at downstream tie in			CY	$150.00	8,889	$ 1,333,333	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 600' length, 2' depth of riffle material.
	Salvage	$ (31,000)	$ (31,000)				$ (31,000)	Utilize M&H cost opinion
	Subtotal	**$ 25,150,240**	**$ 139,140,000**				**$ 56,650,685**	
	Contingency (20%)	$ 5,030,024.20					$ 9,893,698.33	Utilize M&H Contingency for comparison
	Owner's Cost (15%)	$ 3,772,536.30					$ 8,840,648.40	Utilize M&H Owner's Cost
	Baseline Studies, Engineering and Permitting						$ 1,797,565.98	Assume 3.5% excluding sediment disposal costs
	Construction Management, Biological Monitoring & O&M						$ 1,227,180.57	Assume 2% excluding sediment disposal costs
	Total	$ 33,437,800	$ 139,140,000				**$ 78,409,400**	

Notes:
1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.
3. WSP unit costs based on Mead & Hunt Relicensed Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.

Consumers Energy
Rogers Hydroplant
Decommissioning Cost Evaluation - Non-Power Operation

Structure	Scope Item	Meade & Hunt Decommissioning Cost	Unit	Unit Cost	Quantity	WSP Opinion of Cost	WSP Notes
Impact Study	Environmental/Social Impact Study	$ 225,289					Cost included in baseline studies, engineering & permitting.
Substation	Continued use of 46-kV substation	$ 59,039				$ 59,039	Utilize M&H Cost Opinion.
	Remove overhead lines between Powerhouse and MTB No. 1	$ 7,102				$ 7,102	Utilize M&H Cost Opinion.
General Site	Remove storage building	$ 94,462				$ 94,462	Utilize M&H Cost Opinion.
	Survey site for environmental contamination	$ 2,362					Cost included in baseline studies, engineering & permitting.
Powerhouse	Leave powerhouse intact	$ 245,565				$ 245,565	Utilize M&H Cost Opinion.
	Survey for contaminants	$ 2,362					Cost included in baseline studies, engineering & permitting.
	Remove or lay-up equipment	$ 88,558				$ 88,558	Utilize M&H Cost Opinion.
Spillway	Modify spillway to maintain flow/pond level	$ 88,667				$ 88,667	Utilize M&H Cost Opinion.
Reservoir	Fish Passage		VLF	$50,000.00	26	$ 1,300,000	Assume 42' vertical feet, downstream = 835', reservoir normal = 861'
	Salvage					$ -	Utilize M&H cost opinion
	Subtotal	**$ 813,406**				**$ 1,883,393**	
	Contingency (10%)	$ 81,340.60				$ 188,339.30	Utilize M&H Contingency for comparison
	Owner's Cost (15%)	$ 122,010.90				$ 282,508.95	Utilize M&H Owner's Cost
	Engineering and Permitting					$ 696,207.76	3.5% +impact study+$400k for fish ladder design + $5K for environmental contaminants survey (do not need to survey reservoir).
	Construction Management & Biological Monitoring (10%)					$ 188,339.30	Assume 10% of subtotal. No biological monitoring required.
	Total	**$ 1,016,758**				**$ 3,238,788**

Rogers Hydropower
Decommissioning Cost Evaluation - Partial Removal

Structure	Scope Item	Meade & Hunt Decommissioning Cost	Unit	WSP Unit Cost	Quantity	WSP Opinion of Cost	WSP Notes
Impact Study	Environmental/Social Impact Study	$ 351,915					Cost included in baseline studies, engineering & permitting.
Substation	Continued use of 46 kV substation	$ 59,039				$ 59,039	Utilize M&H Cost Opinion.
	Remove overhead lines between Powerhouse and MTB No. 1	$ 7,102				$ 7,102	Utilize M&H Cost Opinion.
	Allow distribution line from plant bus	$ 7,102				$ 7,102	Utilize M&H Cost Opinion.
General Site	Remove security fencing	$ 4,719				$ 4,719	Utilize M&H Cost Opinion.
	Remove storage building	$ 94,462				$ 94,462	Utilize M&H Cost Opinion.
	Remove plant access road	$ 3,539				$ 3,539	Utilize M&H Cost Opinion.
	Remove septic tank / drain field	$ 11,808				$ 11,808	Utilize M&H Cost Opinion.
	Survey site for environmental contamination	$ 2,362					Cost included in baseline studies, engineering & permitting.
	Remove piezometers	$ 25,980				$ 25,980	Utilize M&H Cost Opinion.
Powerhouse	Leave powerhouse intact	$ -				$ -	
	Survey for contaminants	$ 2,362					Cost included in baseline studies, engineering & permitting.
	Remove or lay-up equipment						
	Remove all powerhouse equipment	$ 191,663				$ 191,663	Utilize M&H Cost Opinion.
	Demolish & remove powerhouse including intake/tailrace, retaining wall & aprons	$ 805,338				$ 1,207,992	Utilize M&H Cost Opinion plus 50% contingency. Quantity verification needed to confirm M&H assumptions.
Spillway	Modify spillway to maintain flow/pond level					$ -	
	Demolish and remove emergency spillway including concrete weir and apron	$ 21,822				$ 21,822	Utilize M&H Cost Opinion.
Earth Dam and Reservoir/River Channel	Drain 44B-acre reservoir	$ 496,424				$ 981,403	Utilize M&H Cost Opinion. 30K CY riprap in erosion control measures line item utilized for temporary spillway protection. Include coffer dam cost.
	Demolish/remove portion of earth dam to create sufficient breach-Excavation	$ 1,022,230	CY	$14.64	69,833	$ 1,022,355	Utilize M&H Cost Opinion.
	Demolish/remove portion of earth dam to create sufficient breach-Reinforced concrete demo	$ 89,033	CY	$207.00	430	$ 89,010	Utilize M&H Cost Opinion.
	Demolish/remove portion of earth dam to create sufficient breach- sheet piling removal	$ 15,572	SF	$2.36	6,600	$ 15,576	Utilize M&H Cost Opinion.
	Demolish/remove entire earth dam and core wall					$ -	
	Remove accumulated non-contaminated sediments - Dam Pilot Channel	$ 1,615,509	CY	$11.81	136,800	$ 1,615,608	Utilize M&H Cost Opinion.
	Remove accumulated non-contaminated sediments - Reservoir Dredging	$ 16,716,597		$7.09	2,002,987	$ 14,208,342	Utilize M&H Cost Opinion for dredging of 200' wide channel. Prorate at 85% of volume due to impoundment created by weir.
	Remove accumulated non-contaminated sediments - Mide/Dennis	$ 118,077		$118,077.00	1	$ 118,077	Utilize M&H Cost Opinion.
	Remove contaminated Sediments - Removal		CY	$7.09	54,143	$ 383,871	Assume 10% of reservoir requires dredging at average depth of 12" prior to drawdown to remove contaminated sediment. Dependent on sediment characterization.
	Remove contaminated Sediments - Disposal		ton	$70.00	108,285	$ 7,579,951	Disposal of contaminated sediment. Use Kiewit unit rate.
	Seed former reservoir bottom	$ 625,976					Revised cost included below.
	Habitat Restoration						Revised cost included below.
	Apply erosion control measures - silt fence	$ 17,118	LF	$5.00	18,000	$ 90,000	Utilize M&H quantity. Adjust unit price based on similar projects.
	Apply erosion control measures - erosion mat	$ 40,929	SY	$0.24			Cost not included. Assume jute mat on banks and straw & tackifier during seeding that is included in other items.
	Apply erosion control measures - riprap protection	$ 1,765,586	CY	$150.00	5,000	$ 750,000	Riprap/engineering protection costs for temporary diversion to $150/CY. Assume 5000 CY for temporary protection. Additional riprap captured in Bank Stabilization - Hard Structure & Channel Creation - Riffle Section items.
	Reuse (grading) of non-contaminated excavated & dredged material		CY	$8.00	2,073,830	$ 16,590,641	Additional effort to grade/rework material excavated/dredged for specific habitat creation.
	Bank Stabilization - Hard Structure		LF	$333.33	4,908	$ 1,635,984	Main channel = 16,360 LF, Other Tributary tie in = 3,430 LF; assume 15% hard structure banks for only main channel banks.
	Bank Stabilization - Live Stakes & Jute Mat		LF	$54.53	34,672	$ 1,890,664	Main channel = 16,360 LF, Other Tributary tie in = 3,430 LF; assume 85% for main channel banks, assume all other banks
	Habitat Restoration - Seeding		Acre	$3,100.00	225	$ 697,500	Acreage outside of dredged channel, assume 200' width for main river channel, 50' width for tributary connections. Include footprint of earthen dam and spillway
	Habitat Restoration - Planting		Acre	$3,072.00	113	$ 345,600	Assume 50% of seeded area is planted, assume 10' OC spacing, 480 plants per acre, #2 container 1-2' high, $6.45/plant; assume 50% of acreage is planted
	Concrete weir installation		LF	$5,050.00	200	$ 1,010,000	Assume weir width of 4' and height of 9' (6' drop height + 3' foundation concrete). Assume reinforced marine concrete has a unit cost of $700/CY. Pile cost included.
	Fish Passage		VLF	$50,000.00	9	$ 450,000	Assume 8 FT drop from weir + 3 FT below downstream water elevation.
	Channel creation - Riffle Section at downstream tie in		CY	$150.00	4,444	$ 666,667	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 300' length, 2' depth of riffle material.
	Salvage	$ (31,000)				$ (31,000)	Utilize M&H cost opinion
	Subtotal	**$ 22,326,729**				**$ 51,745,480**	
	Contingency (10%)	$ 2,232,673.00				$ 5,174,548.01	Utilize M&H Contingency for comparison
	Owner's Cost (15%)	$ 3,345,893.85				$ 7,761,822.22	Utilize M&H Owner's Cost
	Baseline Studies, Engineering and Permitting					$ 1,945,793.45	Assume 3.5% excluding sediment disposal costs, add 200k for concrete weir design
	Construction Management, Biological Monitoring & O&M					$ 883,519.54	Assume 3% excluding sediment disposal costs
	Total	$ 27,882,174				**$ 67,510,964**	

Notes:
1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.
3. WSP unit costs based on Meade & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost databases. Additional cost assumptions stated above.
4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

Hardy Hydroplant
Decommissioning Cost Evaluation - Full Removal

Structure	Scope Item	Meade & Hunt Decommissioning Cost	Kiewit Decommissioning Cost	Unit	WSP Unit Cost	Quantity	WSP Opinion of Cost	WSP Notes
Impact Study	Environmental/Social Impact Study	$ 2,105,600	$ 2,100,000					Cost included in baseline studies, engineering & permitting.
Substation	Remove transformer & lines from powerhouse to 186kV	$ 115,858	$ 100,000				$ 115,858	Utilize M&H Cost Opinion.
General Site	Remove security fencing	$ 14,157	$ 600,000				$ 14,157	Utilize M&H Cost Opinion.
	Remove plant access road	$ 374,562					$ 374,562	Utilize M&H Cost Opinion.
	Remove septic tank / drain field	$ 11,808					$ 11,808	Utilize M&H Cost Opinion.
	Survey site for environmental contamination	$ 2,362						Cost included in baseline studies, engineering & permitting.
	Remove piezometers	$ 172,415					$ 172,415	Utilize M&H Cost Opinion.
Intake Structure	Demolish & remove intake structure & footbridge	$ 2,582,603	$ 2,600,000				$ 2,582,603	Utilize M&H Cost Opinion.
Powerhouse	Leave powerhouse intact	$ -	$ 4,100,000				$ -	
	Survey for contaminants	$ 2,362						Cost included in baseline studies, engineering & permitting.
	Remove or lay-up equipment						$ -	
	Remove all powerhouse equipment	$ 387,618					$ 387,618	Utilize M&H Cost Opinion.
	Demolish & remove powerhouse including spill tubes, intake/tailrace, retaining wall & apron	$ 3,739,631					$ 3,739,631	Utilize M&H Cost Opinion.
Spillway	Modify spillway to maintain flow/pond level						$ -	
	Demolish and remove emergency spillway	$ 1,756,585					$ 1,756,585	Utilize M&H Cost Opinion.
	Partial Spillway Scope		$ 14,000,000					
	Spillway: concrete demolition, removal and disposal		$ 1,500,000					Kiewit cost not included. Assume concrete volume captured in M&H item for earthen dam, core wall & emergency spillway accounts for this.
	Spillway: Site restoration, planting, seeding		$ 1,500,000				$ -	Kiewet cost not included. Included in WSP planting/seeding costs.
Earth Dam and Reservoir/River Channel	Drain 3,902-acre reservoir	$ 392,400	$ 400,000				$ 392,400	Utilize M&H Cost Opinion.
	Construction of temporary spillway for drawdown		$ 11,000,000					Kiewit cost not included. Costs included for temporary riprap protection and channel riffle material below. Unit rate increased to $150/CY.
	Demolish/remove portion of earth dam to create sufficient breach						$ -	
	Reconstruct roadway - Road	$ 779,306	$ 14,000,000				$ 779,306	Kiewit roadway reconstruction costs not included. Assume bridge costs contain necessary superstructure to set deck at sufficient elevation to reduce sleep slope that requires roadway realignment. Contingent on additional studies.
	Reconstruct roadway - Bridge	$ 6,280,000	$ 25,000,000	SF	$ 330	24,500	$ 12,127,500	M&H Estimate revised per 2022 MDOT cost spreadsheet. New Bridge = $330/SF. Include 50% contingency.
	Demolish/remove entire earth dam, core wall and emergency spillway - excavation	$ 20,823,436	$ 23,400,000	CY	$14.64	1,422,540	$ 20,823,436	Utilize M&H Cost Opinion.
	Demolish/remove entire earth dam, core wall and emergency spillway - reinforced concrete demo	$ 2,174,063		CY			$ 2,174,063	Utilize M&H Cost Opinion.
	Demolish/remove entire earth dam, core wall and emergency spillway - sheet piling removal	$ 419,982		SF			$ 419,982	Utilize M&H Cost Opinion.
	Remove accumulated non-contaminated sediments - Dam Pilot Channel	$ 1,681,641	$ 18,000,000	CY	$11.81	142,400	$ 1,681,744	Utilize M&H Cost Opinion
	Remove accumulated non-contaminated sediments - Reservoir Dredging	$ 7,433,606		CY	$7.09	1,348,407	$ 9,560,206	Assumes dredging 300' wide main channel is re-established with limited dredging. Assume 1048407 CY (from M&H opinion) required to remove fine grain sediments and re-establish channel where required. Secondary tributary connections = 36,000LF, assume 50' width dredged, 4' depth avg = 300,000 CY .
	Remove accumulated non-contaminated sediments - Mob/Demob	$ 354,231		LS	$118,077.00	3	$ 354,231	Utilize M&H Cost Opinion
	Remove contaminated Sediments - Removal			CY	$7.09	629,523	$ 4,463,316	Assume 10% of reservoir requires dredging at average depth of 12" prior to drawdown to remove contaminated sediment. Dependent on sediment characterization.
	Remove contaminated Sediments - Disposal		$ 150,000,000	ton	$70.00	1,259,045	$ 88,133,173	Disposal of contaminated sediment; Kiewit unit rate.
	Seed former reservoir bottom	$ 5,915,473	$ 5,900,000					Revised cost included below.
	Apply erosion control measures - silt fence	$ 95,100	$ 2,200,000	LF	$5.00	100,000	$ 500,000	Utilize M&H quantity. Adjust unit price based on similar projects.
	Apply erosion control measures - erosion mat	$ 385,216		SY	$0.24	1,600,000		Cost not included. Assume jute mat on banks and straw & tackifier during seeding that is included in other items.
	Apply erosion control measures - riprap protection	$ 1,769,586		CY	$150.00	5,000	$ 750,000	Increase riprap protection costs for temporary diversion to $150/CY. Assume 5000 CY for temporary protection. Additional riprap captured in Bank Stabilization - Hard Structure & Channel Creation - Riffle Section items.
	Reuse (grading) of non-contaminated excavated & dredged material			CY	$8.00	2,913,347	$ 23,306,776	Additional effort to grade/rework material excavated/dredged for specific habitat creation.
	Grading & surface preparation/amendments			Acre	$6,700.00	2,877	$ 19,276,996	Grading and reworking of newly exposed sediments within reservoir.
	Bank Stabilization - Hard Structure		$ 65,000,000	LF	$333.33	26,760	$ 8,919,911	Main channel = 89,200 LF, Other Tributary tie in = 36,000 LF; assume 15% hard structure banks for only main channel banks
	Bank Stabilization - Live Stakes & Jute Mat			LF	$54.53	223,640	$ 12,195,089	Main channel = 89,200 LF, Other Tributary tie in = 36,000 LF; assume 85% for main channel banks, assume all other banks
	Habitat Restoration - Seeding			Acre	$3,100.00	2,877	$ 8,919,207	Acreage outside of dredged channel, assume 300' width for main river channel, 50' width for tributary connections, include footprint of earthen dam and spillway
	Habitat Restoration - Planting			Acre	$3,072.00	1,707	$ 5,243,604	Assume full planting in channel floodplain for riparian buffer, assume 50% planting in newly created upland outside floodplain. assume 10' OC spacing, 480 plants per acre, #2 container 1-2' high, $6.40/plant; assume 50% of acreage is planted.
	Channel creation - Riffle Section at downstream tie in			CY	$186.00	22,222	$ 4,133,333	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 300' width, 1000' length, 2' depth of riffle material.
	Salvage	$ (135,398)					$ (135,398)	Utilize M&H cost opinion
	Subtotal	**$ 59,634,203**	**$ 341,400,000**				**$ 233,174,112**	
	Contingency (10%)	$ 5,963,420.30					$ 23,317,411.19	Utilize M&H Contingency for comparison
	Owner's Cost (15%)	$ 8,945,130.45					$ 34,976,116.79	Utilize M&H Owner's Cost
	Baseline Studies, Engineering and Permitting						$ 5,076,432.85	Assume 3.5% excluding sediment disposal costs
	Construction Management, Biological Monitoring & O&M						$ 2,900,818.77	Assume 2% excluding sediment disposal costs
	Total	$ 74,542,754	$ 341,400,000				**$ 299,444,891**	

Notes:
1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.
3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost

Spillway	Modify spillway to maintain flow/pond level						$ -	-
	Demolish and remove emergency spillway						$ -	-
	Partial Spillway Scope		$ 14,000,000				$ -	-
								Kiewit cost not included. Assume concrete cutting required to install dam for earthen dam to remain in place, emergency spillway and bridge for now.
	Spillway: concrete demolition, removal and disposal		$ 1,500,000					Kiewit cost not included. Included in MSP planting/seeding costs.
	Spillway: site restoration, planting, seeding		$ 1,500,000				$ -	
	Drain 3,962-acre reservoir	$ 392,400	$ 400,000				$ 392,400	Utilize M&H Cost Opinion.
	Construction of temporary spillway for drawdown		$ 11,000,000					Kiewit cost not included. Costs included for temporary riprap protection and channel. Riffle material below. Unit rate increased to $150/CY.
	Demolish/remove portion of earth dam to create sufficient breach - Excavation	$ 16,499,160		CY	$14.64	1,140,000	$ 16,689,600	Utilize M&H unit cost. No Kiewit estimate for partial removal. Assume 2:1 slope from top of weir to top of existing earth dam embankment.
	Demolish/remove portion of earth dam to create sufficient breach - Reinforced concrete dams	$ 776,452		CY	$307.00	2,750	$ 726,250	Utilize M&H Cost Opinion.
	Demolish/remove portion of earth dam to create sufficient breach - Sheet	$ 113,254		SF	$2.30	49,000	$ 112,700	Utilize M&H Cost Opinion.
Earth Dam and Reservoir/River Channel	Reconstruct roadway - flood	$ 779,306	$ 14,000,000				$ 779,306	Kiewit roadway reconstruction costs not included. Assume bridge costs contain necessary superstructure to set deck at sufficient elevation to reduce steep slope that require roadway realignment.
	Reconstruct roadway - Bridge	$ 6,260,000	$ 25,000,000	SF	$330.00	24,500	$ 12,127,000	Kiewit estimate revised per 2022 MDOT cost spreadsheet. New bridge + approx. 1,000 LF roadway.
	Demolish/remove entire earth dam, core wall and emergency spillway			CY	$14.64	1,140,000	$ 16,689,600	Utilize M&H Cost Opinion.
	Remove accumulated non-contaminated sediments - Sehl-Pilot Channel	$ 1,681,641		CY	$11.81	142,400	$ 1,681,744	Utilize M&H Cost Opinion.
	Remove accumulated non-contaminated sediments - Reservoir Dredging	$ 7,433,606	$ 18,000,000	CY	$7.08	1,191,148	$ 8,445,225	Assumes dredging 100' wide main channel is re-established with limited dredging. Assume 1064647 CY (from M&H options) required to remove fine grain sediments and re-establish channel where required. Prorate at 85% to account for no dredging in areas where channel naturally forms. Assuming connectivity = 84,000LF, assume 50' width dredged, of depth avg = 283,950 CY.
	Remove accumulated non-contaminated sediments - Weir/Sediment	$ 267,915		CY	$139,077.36	2	$ 267,915	Utilize M&H Cost Opinion.
	Remove contaminated Sediments - Removal			CY	$7.08	629,523	$ 4,463,249	Assume 30% of reservoir requires dredging at average depth of 14' prior to drawdown to remove contaminated sediment. Dependent on sediment characterization.
	Remove contaminated Sediments - Disposal		$ 100,000,000	tons	$70.00	1,358,340	$ 95,113,172	Disposal of contaminated sediment
	Erosion control measures	$ 9,915,470	$ 4,000,000	LF				Kiewit cost not included.
	Apply erosion control measures - silt fence	$ 661,031		LF	$5.00	132,000	$ 660,000	Utilize M&H Cost Opinion. Assume quantity. Adjust unit price based on similar projects.
	Apply erosion control measures - erosion mat	$ 385,216	$ 2,200,000	SF	$0.24	1,600,000		Cost not included. Assume jute mat on banks and below & shoreline stating seeding that is included in other items.
	Apply erosion control measures - riprap protection	$ 1,769,586		CY	$150.00	5,000	$ 750,000	Increase riprap protection costs for temporary diversion to 3,000CY. Assume 2,000 CY for temporary protection. Additional riprap captured in Site Stabilization - Hard Structure & Channel Creation - Riffle Section Items
	Reuse (grading) of non-contaminated excavated & dredged material			CY	$8.00	2,473,546	$ 19,788,368	Grading and reworking of newly exposed sediments within reservoir.
	Grading & surface preparation/amendments			Acre	$6,700.00	2,603	$ 18,760,100	Main channel = 84,000 LF x 200ft = 16,800,000 SF = 385AC. Assume 15% hard structure banks for only main channel banks
	Bank Stabilization - Hard Structure			LF	$333.33	26,760	$ 8,919,911	Main channel banks = 84,000 LF. Tributaries = 26,000 LF, assume non-hard structure banks.
	Bank Stabilization - Live Stakes & Jute Mat			LF	$54.53	223,646	$ 12,195,084	Main channel banks, assume all other banks
	Habitat Restoration - Seeding		$ 65,000,000	Acre	$3,100.00	2,603	$ 8,069,300	Acreage outside of dredged channel, assume 300' width for main river channel, 50' width for tributary connections. Include footprint of earthen dam and spillway.
	Habitat Restoration - Planting			Acre	$3,072.00	1,402	$ 4,305,456	Assume full planting in channel floodplain for riparian buffer, assume 50% planting in newly created upland outside floodplain, assume 10' OC spacing, 490 plants per acre, 42 creosote x 2" high, 56 dogbane, assume 50% of acreage is planted
	Channel creation - Riffle Section at downstream tie in			CY	$150.00	11,111	$ 1,666,667	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 600' length, 2' depth of riffle material
	Concrete Weir Installation			LF	$5,050.00	300	$ 1,515,000	Assume weir taken at a skip height of 10' (top height = 7' freeboard + 3' head). Assume reinforced marine concrete has a unit cost of $7561/CY. Pile cost included.
	Fish Passage			Vol	$50,000.00	9	$ 450,000	Assume 6 FT drop from weir + 3 FT below downstream water elevation.
	Salvage	$ (125,000)					$ (125,000)	Utilize M&H cost opinion
	Subtotal	$ 51,863,350	$ 310,230,000				$ 218,791,481	
	Contingency (10%)	$ 5,186,335					$ 21,879,148	Utilize M&H Contingency for comparison
	Kiewit Profit (10%)	$ 7,780,005					$ 32,818,722	Utilize M&H Contingency for comparison
	Baseline Studies, Engineering and Permitting						$ 4,972,000	Assume 2% excluding sediment disposal costs plus local for concrete sales and sewage design
	Construction Management, Ecological Monitoring & O&M						$ 7,812,000	Assume 2% excluding sediment disposal costs
	TOTAL	$ 64,829,690	$ 310,230,000				$ 286,394,351	

Notes:
1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Meade & Hunt Removal Estimate includes $2,000,000 for Sediment Disposal. Kiewit Estimate includes exposed reservoir bottom will require grading, surface amendments, seeding and planting.
3. MSP unit costs based on Meade & Hunt Refinement Studies, Kiewit Infrastructure Co, Cost Estimates and MSP's internal cost database. Additional cost assumptions stated above.
4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

Decommissioning Cost Evaluation - Partial Removal

Structure	Scope Item	Meade & Hunt Decommissioning Cost	Unit	WSP Unit Cost	Quantity	WSP Opinion of Cost	WSP Notes
Impact Study	Environmental/Social Impact Study	$ 771,005					Costs included in Engineer baseline studies
Substation	Remove power cable between powerhouse and MTB No. 1	$ 71,024				$ 71,024	Utilize M&H Cost Opinion.
General Site	Remove security fencing	$ 3,067				$ 3,067	Utilize M&H Cost Opinion.
	Remove storage building	$ 10,000				$ 10,000	Utilize M&H Cost Opinion.
	Remove office/storage building	$ 94,462				$ 94,462	Utilize M&H Cost Opinion.
	Remove plant access road	$ 5,899				$ 5,899	Utilize M&H Cost Opinion.
	Remove septic tank / drain field	$ 11,808				$ 11,808	Utilize M&H Cost Opinion.
	Survey site for environmental contamination	$ 2,382				-	Costs included in Engineer baseline studies
Powerhouse	Remove piezometers	$ 18,895				$ 18,895	Utilize M&H Cost Opinion.
	Leave powerhouse intact	$ -				$ -	
	Survey for contaminants	$ 2,382				-	Costs included in Engineer baseline studies
	Remove all powerhouse equipment	$ 265,954				$ 265,954	Utilize M&H Cost Opinion.
	Demolish and remove powerhouse turbine bay including intake/tailrace, retaining walls, and aprons	$ 1,003,075				$ 1,003,075	Utilize M&H Cost Opinion.
Spillway	Demolish and remove powerhouse generator hall					$ -	
	Modify spillway to maintain flow/pond level					$ -	
	Demolish and remove spillway including concrete weir and apron.	$ 2,935,154				$ 2,935,154	Utilize M&H Cost Opinion.
Earth Dam and Reservoir/River Channel	Drain 1,209-acre reservoir	$ 1,170,076				$ 1,170,076	Utilize M&H Cost Opinion.
	Demolish/remove portion of earth dam to create sufficient breach - Excavation	$ 498,139	CY	$14.64	34,030	$ 498,109	Assume same quantity & unit rate as M&H
	Demolish/remove portion of earth dam to create sufficient breach - Reinforced concrete demo	$ 102,492	CY	$207.00	495	$ 102,465	Utilize M&H Cost Opinion.
	Demolish/remove portion of earth dam to create sufficient breach - sheet piling removal	$ 7,786	SF	$2.36	3,300	$ 7,788	Utilize M&H Cost Opinion.
	Demolish/remove entire earth dam and core wall					$ -	
	Remove accumulated sediments (non-contaminated) - river pilot channel	$ 1,617,517	CY	$11.81	136,970	$ 1,617,616	Utilize M&H Cost Opinion.
	Remove accumulated sediments (non-contaminated) - reservoir dredging	$ 27,277,139	CY	$7.09	3,270,003	$ 23,184,319	Assumes dredging 50 acre channel. Utilize M&H quantity. Assume this includes connection to Little Muskegon River. Prorate at 85% to account for impoundment section not requiring dredging.
	Remove accumulated sediments (non-contaminated) - Mob/Demob	$ 236,154	LS	$118,077.00	2	$ 236,154	Utilize M&H Cost Opinion.
	Seed former reservoir bottom	$ 1,658,819					Revised cost included below.
	Apply erosion control measures - silt fence	$ 18,069	LF	$5.00	19,000	$ 95,000	Utilize M&H quantity. Adjust unit price based on similar projects.
	Apply erosion control measures - erosion mat	$ 108,342	SY	$0.24	450,000		M&H Cost not included. Assume jute mat on banks and straw & tackifier during seeding is included in other items below.
	Apply erosion control measures - riprap protection	$ 1,769,586	CY	$150.00	5,000	$ 750,000	Increase riprap protection costs for temporary diversion to $150/CY. Assume 5000 CY for temporary protection. Additional riprap captured in Bank Stabilization - Hard Structure & Channel Creation - Riffle Section items.
	Contaminated Sediment Dredging		CY	$7.09	195,052	$ 1,382,919	Assume 10% of reservoir requires dredging at average depth of 12" prior to drawdown to remove contaminated sediment. Dependent on sediment characterization.
	Contaminated Sediment Disposal		Ton	$70.00	390,104	$ 27,307,280	Unit cost from Kiewit estimate
	Reuse (grading) of non-contaminated excavated & dredged material		CY	$9.00	3,304,033	$ 26,432,262	Additional effort to grade/rework material excavated/dredged for specific habitat creation.
	Grading and surface preparation amendments		ACRE	$6,700.00	700	$ 4,690,000	Grading and reworking of newly exposed sediments within reservoir.
	Bank Stabilization - Hard Structure		LF	$333.33	6,420	$ 2,139,979	Main channel = 21,400 LF, Tributary Tie in to Little Muskegon River = 7,535; Other Tributary tie in = 1,135 LF; assume 15% hard structure banks for only main channel banks
	Bank Stabilization - Live Stakes & Jute Mat		LF	$54.53	53,720	$ 2,929,352	Main channel = 21,400 LF, Tributary Tie in to Little Muskegon River = 7,535; Other Tributary tie in = 1,135 LF; assume 85% for main channel banks, assume all other banks
	Habitat Restoration - Seeding		Acre	$3,100.00	929	$ 2,881,165	Acreage outside of dredged channels and impoundment preserved by weir, assume 350' width for main river channel, assume 200' channel width for Little Muskegon River tie in, assume 100' width for other tributary connections. Assume all is seeded.
	Habitat Restoration - Planting		Acre	$3,072.00	465	$ 1,427,573	Acreage outside of dredged channels and impoundment preserved by weir, assume 350' width for main river channel, assume 200' channel width for Little Muskegon River tie in, assume 100' width for other tributary connections. assume 10' OC spacing, 48 plants per acre, #2 container 1-2' high, $6.40/plant; assume 50% of acreage is planted
	Channel creation - Riffle Section at downstream tie in		CY	$150.00	6,667	$ 1,000,000	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 300' width, 300' length, 2' depth of riffle material.
	Fish Passage w/ sea lamprey control		VLF	$50,000.00	9	$ 450,000	Assume 6 FT drop from weir + 3 FT below downstream water elevation.
	Concrete Weir Installation		LF	$5,050.00	300	$ 1,515,000	Assume weir width of 4' and height of 9' (6' drop height + 3' foundation concrete). Assume reinforced marine concrete has a unit cost of $780/CY. Pile cost included.
	Salvage	$ (47,350)				$ (47,350)	Utilize M&H cost opinion
	Subtotal	**$ 39,749,202**				**$ 104,279,337**	
	Contingency (10%)	$ 3,974,920.20				$ 10,427,933.72	Utilize M&H Contingency for comparison
	Owner's Cost (15%)	$ 5,962,380.30				$ 15,641,870.58	Utilize M&H Owner's Cost
	Baseline Studies, Engineering and Permitting					$ 3,094,015.00	Assume 3.5% excluding sediment disposal costs plus 400k for concrete weir/fish passage design
	Construction Management & Biological Monitoring					$ 1,539,457.14	Assume 2% excluding sediment disposal costs
	Total	**$ 49,639,153**				**$ 134,982,374**	

Notes:
1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.
3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.
4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

	Concrete weir installation	$ -	$ 5,050.00	LF	200	$ 1,010,000.00	Assume weir width of 4' and height of 9' (6' drop height + 3' foundation concrete). Assume reinforced marine concrete has a unit cost of $780/CY. Pile cost included.
	Bank Stabilization - Hard Structure	$ -	$ 333.33	LF	12896	$ 4,298,623.68	Assume 3H:1V, assume 6' bank, 2' embedment max, 30" thickness D50 = 15" riprap, 2.22 CY/LF bank, $150/CY
	Bank Stabilization - Live stakes and Jute Matting	$ 161,309.00	$ 54.53	LF	51584	$ 2,812,875.52	Assume 3H:1V, assume 3' bank (1 SY per LF), add 30% to jute mat for anchor, Jute Mat = $2.04/SY, Live stakes = $5.47/each, 4 stakes per SY, add .2 CY/LF riprap/reused cobble at $150/CY for jute mat anchor)
	Salvage Value	$ (57,430.00)	$ (57,430.00)	LS	1	$ (57,430.00)	Utilize Mead & Hunt opinion
	Subtotal	**$22,496,945**				**$104,253,503**	
	Contingency					$10,425,350.33	Assume 10% of subtotal excluding cost of contaminated sediment disposal.
	Owner's Cost					$15,638,025.49	Assume 15% of subtotal excluding cost of contaminated sediment disposal.
	Engineering and Permitting					$4,048,872.62	Assume 3.5% of subtotal excluding cost of contaminated sediment disposal + $400K for weir/fish ladder design.
	Construction Management & Biological					$2,085,070.07	Assume 2% of subtotal excluding cost of contaminated sediment disposal.
	Total					**$136,450,822**	

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.

4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

Demolish/remove entire earth dam, core wall, and emergency spillway: Excavation	$ 2,210,369.00	CY	151000	$ 14.64	$ 2,210,369.00	Utilize Mead & Hunt opinion
Demolish/remove entire earth dam, core wall, and emergency spillway: Reinforced concrete demolition	$ 621,161.00	CY	3000	$ 207.00	$ 621,161.00	Utilize Mead & Hunt opinion
Demolish/remove entire earth dam, core wall, and emergency spillway: Sheet piling removal	$ 163,805.00	SF	69425	$ 2.36	$ 163,805.00	Utilize Mead & Hunt opinion
Remove accumulated sediments: Dam pilot channel dredging	$ 1,637,557.00	CY	138667	$ 7.09	$ 983,149.03	Utilize M&H quantity and Kiewit unit cost.
Remove accumulated sediments: Reservoir dredging	$ 10,599,015.00	CY	1549890	$ 7.09	$ 10,988,720.10	Assumes dredging 200' wide main channel is re-established with limited dredging. Assume 1,495,309 CY (from M&H opinion) required to remove fine grain sediments and re-establish channel. Secondary tributary connections =7410 LF, assume 50' width dredged, 4' depth avg = 59,890 CY.
Remove accumulated sediments: Mobilization/Demobilization	$ 118,077.00	LS	1	$ 118,077.00	$ 118,077.00	Utilize Mead & Hunt opinion
Contaminated Sediments - Removal	$ -	CY	106641	$ 7.09	$ 756,087.05	Assume 10% of reservoir requires dredging at average depth of 12" prior to drawdown to remove contaminated sediment. Dependent on sediment characterization.
Contaminated Sediments - Disposal	$ -	Tons	184095	$ 70.00	$ 12,886,645.36	Disposal of contaminated sediment. Unit cost based on Kiewit cost estimate.
Seed former reservoir bottom	$ 698,204.00	AC	568	$ 3,100.00	$ 1,760,800.00	Acreage outside of dredged channels. Mead and Hunt unit cost seems low at $1,185/acre. M&H also quantified 599.1 AC of seeding. Wet meadow seed mix will be approximately $3.1K/AC; upland seed mixes will be slightly less.
Plant former reservoir bottom	$ -	AC	568	$ 3,072.00	$ 1,744,896.00	Acreage outside of dredged channels. No quantity from M&H opinion. Assume 480 plants per acre at $6.40 per plant (#2 container, 1-2' high).
Apply Erosion Control Measures: Silt Fence	$ 15,216.00	LF	16000	$ 5.00	$ 80,000.00	Unit cost adjusted per similar projects.
Apply Erosion Control Measures: Rip Rap Protection	$ 1,769,586.00	CY	5000	$ 150.00	$ 750,000.00	Extra rip-rap for temporary placement for erosion control. Assume higher unit cost than M&H, but less quantity.
Bank Stabilization: Hard Structure	$ -	LF	16172	$ 333.33	$ 5,390,612.76	33,020 LF main channel; 7,410 LF total of 5 tributary tie-ins. Assume 3H:1V, assume 6' bank, 2' embankment max, 30" thickness D50 = 15" riprap, 2.22 CY/LF bank, $150/CY. Assume 20% hard channel structure banks for all banks.

Scope Item	Mead & Hunt Estimate Cost	Unit	WSP Quantity	WSP Unit Cost	WSP Opinion of Cost	WSP Notes
Bank Stabilization: Live stakes and Jute Matting	$ 57,782.00	LF	64688	$ 54.33	$ 3,514,499.04	33,020 LF main channel; 7,410 LF total of 5 tributary tie-ins. M&H erosion mat unit cost was low at $0.24/ SY. Assume 3H:1V, assume 3' bank (1.5' per LF), add 30% to jute mat for anchor, Jute Mat = $2.04/SY, Live stakes =$5.47/each, 4 stakes per SY, add .2 CY/LF riprap/reused cobble at $150/CY for jute mat anchor). Assume 85% of all banks will have this type of stabilization.
Reuse (grading) of non-contaminated excavated and dredged material	$ -	CY	1670701	$ 8.00	$ 13,365,610.40	Additional effort to grade/rework material excavated/dredged for specific habitat creation (non-contaminated sediments).
Grading & Surface Preparation/Amendments	$ -	AC	568	$ 6,700.00	$ 3,805,600.00	Grading and reworking of newly exposed sediments within reservoir.
Channel creation: Riffle section at downstream tie in	$ -	CY	8889	$ 150.00	$ 1,333,333.33	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 600' length, 2' depth of riffle material.
Miscellaneous Items						
Salvage Value	$ (42,763.00)	LS	1	$ (42,763.00)	$ (42,763.00)	Utilize Mead & Hunt opinion
Maintain recreation features	$ -	LS	1	$ -	$ -	To be evaluated. 3 Boat Launches; 1 Canoe Portage; 6 Fishing Access Locations, approximately 38 private boat docks. To be evaluated. No costs included.
Subtotal	**$20,840,099**				**$65,466,447**	
Contingency					$5,257,980.17	Assume 10% of subtotal excluding cost of contaminated sediment disposal.
Owner's Cost					$7,886,970.26	Assume 15% of subtotal excluding cost of contaminated sediment disposal.
Engineering and Permitting					$1,840,293.06	Assume 3.5% of subtotal excluding cost of contaminated sediment disposal.
Construction Management & Biological Monitoring					$1,051,596.03	Assume 2% of subtotal excluding cost of contaminated sediment disposal.
Total					**$81,503,287**	

Notes:
1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.
3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.

Earth Dam and Reservoir/ River Channel						
Drain 661-acre reservoir	$ 673,210.00	LS	1	$ 673,210.00	$ 673,210.00	Utilize Mead & Hunt opinion
Demolish/remove portion of earth dam to create sufficient breach: Excavation	$ 118,569.00	CY	6500	$ 14.64	$ 95,160.00	Utilize M&H unit cost. Assume 3:1 slope from top of weir to top of existing earth dam embankment.
Demolish/remove portion of earth dam to create sufficient breach: Reinforced concrete demolition	$ 6,212.00	CY	129	$ 207.00	$ 26,703.00	Utilize M&H unit cost. Prorate M&H full removal quantity with partial removal of earth dam.
Demolish/remove portion of earth dam to create sufficient breach: Sheet piling removal	$ 5,899.00	SF	2985	$ 2.36	$ 7,045.25	Utilize M&H unit cost. Prorate M&H full removal quantity with partial removal of earth dam.
Remove accumulated sediments: Dam pilot channel dredging	$ 1,637,557.00	CY	138667	$ 7.09	$ 983,149.03	Utilize M&H quantity and Kiewit unit cost.
Remove accumulated sediments: Reservoir dredging	$ 10,599,015.00	CY	1250890	$ 7.09	$ 8,868,810.10	Assumes dredging 200' wide main channel is re-established with limited dredging. Assume 1,498,000 CY (from M&H opinion) required to remove fine grain sediments and re-establish channel in full removal. Prorate at 80.0% to account for no dredging within new impoundment. Secondary tributary connections = 7,430 LF, assume 50' width dredged, 4' depth avg = 54,890 CY.
Remove accumulated sediments: Mobilization/Demobilization	$ 118,077.00	LS	1	$ 118,077.00	$ 118,077.00	Utilize Mead & Hunt opinion
Contaminated Sediments - Removal	$ -	CY	106641	$ 7.09	$ 756,087.05	Assume 10% of reservoir requires dredging at average depth of 12" prior to drawdown to remove contaminated sediment. Dependent on sediment characterization.
Contaminated Sediments - Disposal	$ -	Tons	184095	$ 70.00	$ 12,886,645.36	Disposal of contaminated sediment.
Seed former reservoir bottom	$ 698,204.00	AC	509	$ 3,100.00	$ 1,577,900.00	Acreage outside of dredged channels. Mead and Hunt unit cost seems low at $1,165/acre. M&H also quantified 599.1 AC of seeding. Wet meadow seed mix will be approximately $3.34/AC, upland seed mixes will be slightly less.
Plant former reservoir bottom	$ -	AC	509	$ 3,072.00	$ 1,563,648.00	Acreage outside of dredged channels. No quantity from M&H opinion. Assume 480 plants per acre at $5.40 per plant (#2 container, 1-2' high).
Apply Erosion Control Measures: Silt Fence	$ 15,216.00	LF	16000	$ 5.00	$ 80,000.00	M&H assume $5.00/LF. Seems low by a factor of 5.
Apply Erosion Control Measures: Rip Rap Protection	$ 1,769,586.00	CY	5000	$ 150.00	$ 750,000.00	Extra rip-rap for temporary placement for erosion control. Assume higher unit cost than M&H, but less quantity.

Scope Item	Mead & Hunt Estimate Cost	Unit	WSP Quantity	WSP Unit Cost	WSP Opinion of Cost	WSP Notes
Bank Stabilization: Hard Structure	$ -	LF	13576	$ 333.33	$ 4,525,288.08	26,530 LF main channel. 7,410 LF total of 5 tributaries. Assume 3H:1V, assume 6' bank, 2' embedment max, 30" thickness D50 = 15" riprap, 2.22 CY/LF bank, $150/CY. Assume 20% hard channel structure banks for all banks.
Bank Stabilization: Live stakes and Jute Matting	$ 57,782.00	LF	55264	$ 54.33	$ 3,002,493.12	26,530 LF main channel. 7,410 LF total of 5 tributaries. M&H erosion mat unit cost was low at $0.24/ SY. Assume 3H:1V, assume 3' bank (1.5Y per LF), add 30% to jute mat for anchor, Jute Mat = $2.04/SY, Live stakes = $5.47/each, 4 stakes per SY, add .2 CY/LF riprap/reused cobble at $150/CY for jute mat anchor). Assume 80% of all banks will have this type of stabilization.
Reuse (grading) of non-contaminated excavated and dredged material	$ -	CY	1257101	$ 8.00	$ 10,056,810.40	Additional effort to grade/rework material excavated/dredged for specific habitat creation (non-contaminated sediments).
Grading & Surface Preparation/Amendments	$ -	AC	509	$ 6,700.00	$ 3,410,300.00	Grading and reworking of newly exposed sediments within reservoir.
Channel creation: Riffle section at downstream tie in	$ -	CY	8889	$ 150.00	$ 1,333,333.33	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 600' length, 2' depth of riffle material.
Concrete Weir Installation	$ -	LF	200	$ 5,050.00	$ 1,010,000.00	Assume weir width of 4' and height of 9' (6' drop height + 3' foundation concrete). Assume reinforced marine concrete has a unit cost of $780/CY. Pile cost included.
Installation of Fish Passage	$ -	VLF	9	$ 50,000.00	$ 450,000.00	Assume 6 FT drop from weir + 3 FT below downstream water elevation.
Miscellaneous Items						
Salvage Value	$ (42,763.00)	LS	1	$ (42,763.00)	$ (42,763.00)	Utilize Mead & Hunt opinion
Maintain recreation features	$ -	LS	1	$ -	$ -	To be evaluated. 3 Boat Launches, 1 Canoe Portage, 6 Fishing Access Locations, approximately 36 private boat docks. To be evaluated. No costs included.
Subtotal	**$17,975,444**				**$56,494,532**	
Contingency					$4,360,788.64	Assume 10% of subtotal excluding cost of contaminated sediment disposal.
Owner's Cost					$6,541,182.95	Assume 15% of subtotal excluding cost of contaminated sediment disposal.
Engineering and Permitting					$1,926,276.02	Assume 3.3% of subtotal excluding cost of contaminated sediment disposal + $400K for weir/fish ladder design.
Construction Management & Biological Monitoring					$872,157.73	Assume 2% of subtotal excluding cost of contaminated sediment disposal.
Total					**$70,194,937**	

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.
3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.
4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

Demolish/remove entire earth dam, core wall and emergency spillway: Sheet piling removal	$ 115,613.00	$ -	SF	49000	$ 2.36	$ 115,613.00	Utilize Mead & Hunt opinion
Remove accumulated sediments (non-contaminated): Dam pilot channel dredging	$ 1,659,062.00	$ 5,100,000.00	CY	140488	$ 7.09	$ 996,059.92	Utilize M&H quantity and Kiewit unit cost.
Remove accumulated sediments (non-contaminated): Reservoir dredging	$ 4,125,106.00	$ 5,280,000.00	CY	649000	$ 7.09	$ 4,601,410.00	Assumes dredging 200' wide main channel is re-established with limited dredging. Assume $92,000 CY (from M&H opinion) required to remove fine-grain sediments and re-establish channel. Secondary tributary connections = 6,580 LF, assume 50' width dredged, 4' depth dug = 67,000 CY.
Remove accumulated sediments (non-contaminated): Mobilization/Demobilization	$ 236,154.00	$ -	LS	2	$ 118,077.00	$ 236,154.00	Utilize Mead & Hunt opinion. M&H assume two different mobilizations because of depth of reservoir (>40') being greater than vertical reach of hydraulic dredge (20').
Contaminated Sediments - removal	$ -	$ 12,300,000.00	CY	162301	$ 7.09	$ 1,150,716.45	Assume 10% of reservoir requires dredging at average depth of 12' prior to drawdown to remove contaminated sediment. Dependent on sediment characterization.
Contaminated Sediments - Disposal	$ -	$ 170,420,000.00	Tons	280181	$ 70.00	$ 19,612,655.42	Disposal of contaminated sediment.
Seed former reservoir bottom	$ 1,059,344.00	$ 2,260,000.00	AC	884	$ 3,100.00	$ 2,740,400.00	Mead and Hunt unit cost seems low at about $1,165/acre. Only acreage outside of dredged channels will need to be seeded. Wet meadow seed mix will be approximately $3.31/AC; upland seed mixes will be slightly less.
Plant former reservoir bottom	$ -	$ -	AC	884	$ 3,072.00	$ 2,715,648.00	Acreage outside of dredged channels. No quantity from M&H opinion. Assume 480 plants per acre at $6.40 per plant (#2 container, 1-2' high).
Apply Erosion Control Measures: Silt Fence	$ 20,922.00		LF	22000	$ 5.00	$ 110,000.00	Adjusted unit rate per similar projects.
Apply Erosion Control Measures: Rip-Rap Protection	$ 1,769,586.00		CY	5000	$ 150.00	$ 750,000.00	Uses rip-rap for temporary placement for erosion control. Assume higher unit cost than below, but less quantity.
Bank Stabilization: Hard Structure	$ -	$ 3,700,000.00	LF	9339	$ 333.33	$ 3,112,968.87	(2) 150 LF main channel; 6,580 LF for tributary tie-ins. Assume 3H:1V, assume 6' bank, 2' embedment max., 80" thickness D50 = 15" riprap, 2.2t C1V-F bank, $333/CY. Assume 10% hard channel structure banks for all bank.
Bank Stabilization: Live stakes and Juta Matting	$ 89,081.00		LF	52921	$ 54.33	$ 2,875,197.93	Assume 3H:1V, assume 6' bank, 2' embedment max., Mean erosion rate until cost was low at 96.2ft/1Yr. Assume 3H:1V, assume 3' bank (1.3* per LF), add 30% to juta mat for anchor. Juta Mat = $2.04/SY, Live stakes = $5.47/each, 4 stakes per SY, add .2 CY-F riprap/mixed subtitle at $333/CY for junk mat anchor). Assume 80% of all banks will have this type of stabilization.
Reuse (grading) of non-contaminated excavated and dredged material	$ -	$ -	CY	1062539	$ 8.00	$ 8,500,313.60	Assuming grading for excavated material of earth dam and 60% of dredged material (non-contaminated material).
Grading & Surface Preparation/Amendments	$ -	$ -	AC	884	$ 6,700.00	$ 5,922,800.00	Grading and reworking of newly exposed sediments within reservoir.
Channel creation: Riffle section at downstream tie in	$ -	$ -	CY	18518	$ 150.00	$ 2,777,700.00	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 10'/2' length, 2' depth of riffle material.
Miscellaneous Items							
Salvage Value	$ (36,499.00)	$ (40,000.00)	LS	1	$ (36,499.00)	$ (36,499.00)	Utilize Mead & Hunt opinion
Maintain recreation features	$ -	$ -	LS	1	$ -	$ -	To be evaluated. 4 Boat Launches, 1 Canoe Portage, 1 Fishing Access Location, 2 Swim Areas, approximately 45 private boat docks. No Costs included.
Subtotal	**$19,514,740**	**$216,960,000**				**$65,672,785**	
Contingency						$4,606,012.39	Assume 10% of subtotal excluding cost of contaminated sediment disposal.
Owner's Cost						$6,909,019.47	Assume 15% of subtotal excluding cost of contaminated sediment disposal.

Scope Item	Mead & Hunt Estimate Cost	Kiewit Estimate Cost	Unit	WSP Quantity	WSP Unit Cost	WSP Opinion of Cost	WSP Notes
Engineering and Permitting						$1,612,104.54	Assume 2.5% of subtotal excluding cost of contaminated sediment disposal.
Construction Management & Biological Monitoring						$921,202.60	Assume 2% of subtotal excluding cost of contaminated sediment disposal.
Total						**$79,721,125**	

Notes:
1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.
3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.

Demolish/remove portion of earth dam to create sufficient breach: Excavation	$ 548,347.00	$ -	CY	53700	$ 14.64	$ 786,168.00	Utilize M&H unit cost. No Kiewit estimate for partial removal. Assume 2:1 slope from top of weir to top of existing earth dam embankment.
Demolish/remove portion of earth dam to create sufficient breach: Reinforced concrete demolition	$ 31,058.00	$ -	CY	454	$ 207.00	$ 94,062.87	Utilize M&H unit cost. Prorate M&H full removal quantity with partial removal of earth dam.
Demolish/remove portion of earth dam to create sufficient breach: Sheet piling removal	$ 8,093.00	$ -	SF	7497	$ 2.36	$ 17,692.92	Utilize M&H unit cost. Prorate M&H full removal quantity with partial removal of earth dam.
Remove accumulated sediments (non-contaminated): Dam pilot channel dredging	$ 1,659,062.00	$ 5,100,000.00	CY	140488	$ 7.09	$ 996,059.92	Utilize M&H quantity and Kiewit unit cost.
Remove accumulated sediments (non-contaminated): Reservoir dredging	$ 4,125,106.00	$ 5,280,000.00	CY	566938	$ 7.09	$ 4,019,590.42	Assumes dredging 400' wide main channel is re-established with limited dredging. Assume 660,000CY (From M&H opinion) required to remove fine grain sediments and re-establish channel in full removal. Prorate at 85.9% to account for no dredging within new impoundment. Secondary tributary connections = 9,000 LF; assume 50' width dredged, 4' depth avg = 67,000 CY.
Remove accumulated sediments (non-contaminated): Mobilization/Demobilization	$ 236,154.00	$ -	LS	2	$ 118,077.00	$ 236,154.00	Utilize Mead & Hunt opinion. M&H assume two different mobilizations because of depth of reservoir (>40') being greater than vertical reach of hydraulic dredge (20').
Contaminated Sediments - Removal	$ -	$ 12,300,000.00	CY	162301	$ 7.09	$ 1,150,716.45	Assume 10% of reservoir requires dredging at average depth of 12' prior to drawdown to remove contaminated sediment. Dependent on sediment characterization.
Contaminated Sediments - Disposal	$ -	$ 170,420,000.00	Tons	280181	$ 70.00	$ 19,612,655.42	Disposal of contaminated sediment.
Seed former reservoir bottom	$ 1,059,344.00	$ 2,260,000.00	AC	881	$ 3,100.00	$ 2,731,100.00	Mead and Hunt unit cost seems low at about $1,180/acre. Only acreage outside of dredged channels will need to be seeded. Wet meadow seed mix will be approximately $3,100/AC; upland seed mixes will be slightly less.
Plant former reservoir bottom	$ -	$ -	AC	881	$ 3,072.00	$ 2,706,432.00	Acreage outside of dredged channels. No quantity from M&H opinion. Assume 480 plants per acre at $6/2 containers; 1-2' high.
Apply erosion control measures: Silt Fence	$ 20,922.00		LF	22000	$ 5.00	$ 110,000.00	Unit cost adjusted per similar projects.
Apply Erosion Control Measures: Rip Rap Protection	$ 1,769,586.00		CY	5000	$ 150.00	$ 750,000.00	Items rip-rap for temporary placement for erosion control. Assume higher unit cost than M&H, but less quantity.
Bank Stabilization: Hard Structure	$ -	$ 3,700,000.00	LF	8430	$ 333.33	$ 2,809,971.90	19,125 LF main channel, $380 LF for tributary tie-ins. Assume 3H:1V, assume 8' bank, 2' embankment max, 30" thickness 150 = 10' riprap, 2.2 CY/LF bank, $400/CY. Assume 10% hard channel structure banks for all banks.
Bank Stabilization: Live stakes and Jute Matting	$ 89,081.00		LF	47770	$ 54.33	$ 2,595,344.10	19,125 LF main channel, $380 LF for tributary tie-ins. M&H erosion mat unit cost was low at $2.24/ SY. Assume 3H:1V, assume 3' bank (1.3' per LF), add 30% to jute mat for anchor, Jute Mat = $2.06/SY, Live stakes = $5.47/each, 4 stakes per SY, add .2 CY/LF riprap/erosion control at $333/CY for jute mat anchor). Assume 85% of all banks will have this type of stabilization.
Reuse (grading) of non-contaminated excavated and dredged material	$ -	$ -	CY	690383	$ 8.00	$ 5,523,067.20	Additional effort to grade/rework material excavated/dredged for specific habitat creation. Assuming grading for excavated material of earth dam and 60% of dredged material (non-contaminated material).
Grading & Surface Preparation/Amendments	$ -	$ -	AC	881	$ 6,700.00	$ 5,902,700.00	Grading and reworking of newly exposed sediments within reservoir.
Channel creation: Riffle section at downstream tie-in	$ -	$ -	CY	8889	$ 150.00	$ 1,333,333.33	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 800' length, 2' depth of riffle material.
Concrete Weir Installation	$ -	$ -	LF	200	$ 5,050.00	$ 1,010,000.00	Assume weir width of 4' and height of 9' (6' deep height + 2' foundation concrete). Assume reinforced marine concrete has a unit cost of $780/CY. Pile cost included.

Scope Item	Mead & Hunt Estimate Cost	Kiewit Estimate Cost	Unit	WSP Quantity	WSP Unit Cost	WSP Opinion of Cost	WSP Notes
Installation of Fish Passage	$ -	$ -	VLF	9	$ 50,000.00	$ 450,000.00	Assume 6 FT drop from weir + 3 FT below downstream water elevation.
Miscellaneous Items							
Salvage Value	$ (36,499.00)	$ (40,000.00)	LS	1	$ (36,499.00)	$ (36,499.00)	Utilize Mead & Hunt opinion
Maintain recreation features	$ -	$ -	LS	1	$ -	$ -	To be evaluated - no cost included. 4 Boat Launches, 1 Canoe Portage, 1 Fishing Access Location, 2 Swim Areas, approximately 45 private boat docks

Remove accumulated sediments: Mobilization/Demobilization	$ 118,077.00	LS	1	$ 118,077.00	$ 118,077.00	Utilize Mead & Hunt opinion
Contaminated Sediments - Removal	$ -	CY	0	$ 7.09	$ -	Low risk for contaminated sediments in this impoundment. No costs included.
Contaminated Sediments - Disposal	$ -	Tons	0	$ 70.00	$ -	Low risk for contaminated sediments in this impoundment. No costs included.
Seed former reservoir bottom	$ 866,736.00	AC	583	$ 3,100.00	$ 1,807,300.00	Mead and Hunt unit cost seems low at $1,185/acre. M&H also quantified entire reservoir (743 AC) to be seeded. Only acreage outside of dredged channels will need to be seeded. Wet meadow seed mix will be approximately $3.3/AC, upland seed mixes will be slightly less.
Plant former reservoir bottom	$ -	AC	583	$ 3,072.00	$ 1,790,976.00	Acreage outside of dredged channels. No quantity from M&H opinion. Assume 480 plants per acre at $6.40 per plant (#2 container, 1-2' high).
Apply Erosion Control Measures: Silt Fence	$ 15,216.00	LF	16000	$ 5.00	$ 80,000.00	Unit cost adjusted per similar projects.
Apply Erosion Control Measures: Rip Rap Protection	$ 1,769,586.00	CY	5000	$ 150.00	$ 750,000.00	Extra rip-rap for temporary placement for erosion control. Assume higher unit cost than M&H, but less quantity.
Bank Stabilization: Hard Structure	$ 1,769,586.00	LF	12078	$ 333.33	$ 4,025,959.74	29,005 LF main channel; 2,190 LF Baker Creek tributary. Assume 3H:1V, assume 6' bank, 3" embedment mav, 36" thickness D90 = 12" riprap, 2.2C:1V LF bank, $1593/CY. Assume 20% hand channel structure banks for all banks.
Bank Stabilization: Live stakes and Jute Matting	$ 57,782.00	LF	48312	$ 54.33	$ 2,624,790.96	26,005 LF main channel; 2,190 LF Baker Creek tributary. M&H erosion mat unit cost was low at $0.24/ SY. Assume 3H:1V, assume 3' bank (1.5' per LF), add 30% to jute mat for anchor, Jute Mat = $2.04/SY, Live stakes = $5.47/each, 4 stakes per 5', add .2 CY/LF riprap/reused cobble at $150/CY for jute mat anchor). Assume 80% of all banks will have this type of stabilization.
Reuse (grading) of non-contaminated excavated and dredged material	$ -	CY	846970	$ 8.00	$ 6,775,760.00	Additional effort to grade/rework material excavated/dredged for specific habitat creation.
Grading & Surface Preparation/Amendments	$ -	AC	583	$ 6,700.00	$ 3,906,100.00	Grading and reworking of newly exposed sediments within reservoir.
Channel creation: Riffle section at downstream tie in	$ -	CY	10074	$ 150.00	$ 1,511,111.11	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 680' length, 2' depth of riffle material.
Miscellaneous Items						
Salvage Value	$ (42,166.00)	LS	1	$ (42,166.00)	$ (42,166.00)	Utilize Mead & Hunt opinion
Maintain recreation features	$ -	LS	1	$ -	$ -	1 Boat Launch, 2 Canoe Portages, 3 Fishing Access Locations, approximately 0 private boat docks. To be evaluated. No costs included.
Subtotal	**$17,822,570**				**$35,074,243**	

Scope Item	Mead & Hunt Estimate Cost	Unit	WSP Quantity	WSP Unit Cost	WSP Opinion of Cost	WSP Notes
Contingency					$3,607,424.30	Assume 10% of subtotal
Owner's Cost					$5,411,136.44	Assume 15% of subtotal
Engineering and Permitting					$1,262,598.50	Assume 3.5% of subtotal
Construction Management & Biological Monitoring					$721,484.86	Assume 2% of subtotal
Total					**$47,076,887**	

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.

Drain 212-acre reservoir	$ 883,073.00	LS	1	$ 883,073.00	$ 883,073.00	Utilize Mead & Hunt opinion
Demolish/remove portion of earth dam to create sufficient breach: Excavation	$ 309,598.00	CY	10,910	$ 14.64	$ 309,598.00	Utilize M&H unit cost. Assume 3:1 slope from top of weir to top of existing earth dam embankment.
Demolish/remove portion of earth dam to create sufficient breach: Reinforced concrete demolition	$ 24,846.00	CY	87	$ 207.00	$ 24,846.00	Utilize M&H unit cost. Pronste M&H full removal quantity with partial removal of earth dam.
Remove accumulated sediments: Dam pilot channel dredging	$ 1,628,169.00	CY	137,872	$ 7.09	$ 977,512.48	Utilize M&H quantity and Kiewit unit cost.
Remove accumulated sediments: Reservoir dredging	$ 5,310,604.00	CY	751,970	$ 7.09	$ 5,331,467.39	Assumes dredging 200' wide main channel is re-established with limited dredging. Assume 749,000 CY (from M&H opinion) required to remove fine grain sediments and re-establish channel (not pronsied since reservoir extents under the partial removal option are not anticipated to be wider than that of the full removal channel extents). Secondary tributary connections = 400 LF, assume 50' width dredged, 4' depth avg = 3,970 CY.
Remove accumulated sediments: Mobilization/Demobilization	$ 118,077.00	LS	1	$ 118,077.00	$ 118,077.00	Utilize Mead & Hunt opinion
Contaminated Sediments - Removal	$ -	CY	0	$ 7.09	$ -	Low risk for contaminated sediments in this impoundment.
Contaminated Sediments - Disposal	$ -	Tons	0	$ 70.00	$ -	Low risk for contaminated sediments in this impoundment.
Seed former reservoir bottom	$ 209,461.00	AC	167	$ 3,100.00	$ 517,700.00	Mead and Hunt unit cost seems low at about $1,185/acre. Only acreage outside of dredged channels will need to be seeded. Wet meadow seed mix will be approximately $3.1k/AC. upland seed mixes will be slightly less.
Plant former reservoir bottom	$ -	AC	167	$ 3,072.00	$ 513,024.00	Acreage outside of dredged channels. No quantity from M&H opinion. Assume 480 plants per acre at $5.40 per plant (#2 container, 1-2' high).
Apply Erosion Control Measures: Silt Fence	$ 7,608.00	LF	8,000	$ 5.00	$ 40,000.00	Unit cost adjusted per similar projects.
Apply Erosion Control Measures: Rip Rap Protection	$ 1,769,586.00	CY	5,000	$ 150.00	$ 750,000.00	Extra rip-rap for temporary placement for erosion control. Assume higher unit cost than M&H, but less quantity.
Bank Stabilization: Hard Structure	$ 1,769,586.00	LF	6,716	$ 333.33	$ 2,238,644.28	28,390 LF main channel; 400 LF tributary tie-in. Assume 3H:1V, assume 6' bank, 2' embedment max, 35° thickness CSD = 15" riprap, 2.22 CY/LF bank, $150/CY. Assume 20% hand channel structure banks for all banks.
Bank Stabilization: Live stakes and Jute Matting	$ 17,816.00	LF	26,864	$ 54.33	$ 1,459,521.12	28,390 LF main channel; 400 LF tributary tie-in. M&H erosion mat unit cost was low at $0.24/ SY. Assume 3H:1V, assume 3' bank (1.3' per LF), add 30% to jute mat for anchor, Jute Mat = $2.04/SY, Live stakes = $5.47/each, 4 stakes per SY, add .2 CY/LF riprap/reused cobble at $150/CY for jute mat anchor). Assume 80% of all banks will have this type of stabilization.
Reuse (grading) of non-contaminated excavated and dredged material	$ -	CY	900,752	$ 8.00	$ 7,206,016.00	Additional effort to grade/rework material excavated/dredged for specific habitat creation.
Grading & Surface Preparation/Amendments	$ -	AC	167	$ 6,700.00	$ 1,118,900.00	Grading and reworking of newly exposed sediments within reservoir.
Channel creation: Riffle section at downstream tie in	$ -	CY	13,185	$ 150.00	$ 1,977,777.78	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 650' length, 2' depth of riffle material.
Concrete Weir Installation	$ -	LF	200	$ 5,050.00	$ 1,010,000.00	Assume weir width of 4' and height of 9' (6' drop height + 3' foundation concrete). Assume reinforced marine concrete has a unit cost of $760/CY. Pile cost included.

Scope Item	Mead & Hunt Estimate Cost	Unit	WSP Quantity	WSP Unit Cost	WSP Opinion of Cost	WSP Notes
Installation of Fish Passage	$ -	VLF	9	$ 50,000.00	$ 450,000.00	Assume 6 FT drop from weir + 3 FT below downstream water elevation.
Miscellaneous Items						
Salvage Value	$ (39,230.00)	LS	1	$ (39,230.00)	$ (39,230.00)	Utilize Mead & Hunt opinion
Maintain recreation features	$ -	LS	1	$ -	$ -	1 Boat Launch; 1 Canoe Portage, 3 Fishing Access Locations; approximately 3 private boat docks. To be evaluated. No costs included.
Subtotal	**$17,196,485**				**$30,069,494**	
Contingency					$3,006,949.40	Assume 10% of subtotal
Owner's Cost					$4,510,424.09	Assume 15% of subtotal
Engineering and Permitting					$1,452,432.29	Assume 3.5% of subtotal + $400k for weir/fish ladder design.
Construction Management & Biological Monitoring					$601,389.88	Assume 2% of subtotal
Total					**$39,640,690**	

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.

4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

Earth Dam and Reservoir/River Channel						
Drain 1627-acre reservoir	$ 891,478.00	LS	1	$ 891,478.00	$ 891,478.00	Utilize Mead & Hunt opinion
Demolish/remove portion of earth dam to create sufficient breach: Excavation	$ 388,059.00	CY	30295	$ 14.64	$ 443,518.80	Utilize M&H unit cost. Assume 2:1 slope from top of weir to top of existing earth dam embankment.
Demolish/remove portion of earth dam to create sufficient breach: Reinforced concrete demolition	$ 50,728.00	CY	360	$ 207.00	$ 74,565.54	Utilize M&H unit cost. Pronste M&H full removal quantity with partial removal of earth dam.
Remove accumulated sediments: Dam pilot channel dredging	$ 1,625,949.00	CY	137684	$ 7.09	$ 976,179.56	Utilize M&H quantity and Kiewit unit cost.
Remove accumulated sediments: Reservoir dredging	$ 15,657,847.00	CY	1977198	$ 7.09	$ 14,018,335.65	Assumes dredging 200' wide main channel is re-established with limited dredging. Assume 2,269,400 CY (from M&H opinion) required to remove fine grain sediments and re-establish channel. Pronste at $8.9% to account for no dredging within new impoundment. Secondary tributary connections +1,800 LF, assume 50' width dredged, 4' depth avg.= 14,000 CY
Remove accumulated sediments: Reservoir Mobilization/Demobilization	$ 236,106.00	LS	2	$ 118,053.00	$ 236,106.00	Utilize Mead & Hunt opinion. M&H assume two different mobilizations because of depth of reservoir (+40') being greater than vertical reach of hydraulic dredge (30').
Contaminated Sediments - Removal	$ -	CY	0	$ 7.09	$ -	Low risk for contaminated sediments in this impoundment.
Contaminated Sediments - Disposal	$ -	Tons	0	$ 70.00	$ -	Low risk for contaminated sediments in this impoundment.
Seed former reservoir bottom	$ 1,709,396.00	AC	1368	$ 3,100.00	$ 4,240,800.00	Mead and Hunt unit cost seems low at about $1,165/acre. Only acreage outside of dredged channels will need to be seeded. Wet meadow seed mix will be approximately $3.3/LF/AC; upland seed mixes will be slightly less.
Plant former reservoir bottom	$ -	AC	1368	$ 3,072.00	$ 4,202,496.00	Acreage outside of dredged channels. No quantity from M&H opinion. Assume 480 plants per acre at $6.40 per plant (#2 container, 2-2' high).
Apply Erosion Control Measures: Silt Fence	$ 13,314.00	LF	14000	$ 5.00	$ 70,000.00	M&H assume $0.95/LF. Seems low by a factor of 5.
Apply Erosion Control Measures: Rip Rap Protection	$ 1,769,586.00	CY	5000	$ 150.00	$ 750,000.00	Extra rip-rap for temporary placement for erosion control. Assume higher unit cost than M&H, but less quantity.
Bank Stabilization: Hard Structure	$ 1,769,586.00	LF	17328	$ 333.33	$ 5,775,942.24	61,430 LF main channel; 1,890 LF tributary. Assume 3H:1V, assume 6' bank, 2' embedment max, 30" thickness OSD = 15" riprap). 2.22 CY/LF bank, $150/CY. Assume 10% hard channel structure banks but all banks.
Bank Stabilization: Live stakes and Jute Matting	$ 163,717.00	LF	69312	$ 54.33	$ 3,765,720.96	61,430 LF main channel; 1,890 LF tributary. Main erosion risk zone = 5,000 max flow = 30,240 CF. Assume 3H:1V, assume 2' bank (1.5' per LF), add 35% to jute mat for anchor. Jute Mat = $2.04/SY; Live stakes = $5.47/each, 4 stakes per SY, add .2 CY/LF riprap/recused cobble at $150/CY for jute mat anchor). Assume 80% of all banks will have this type of stabilization.
Reuse (grading) of non-contaminated excavated and dredged material	$ -	CY	2145177	$ 8.00	$ 17,161,418.06	Additional effort to grade/rework material excavated/dredged for specific habitat creation.
Grading & Surface Preparation/Amendments	$ -	AC	1368	$ 6,700.00	$ 9,165,600.00	Grading and reworking of newly exposed sediments within reservoir.
Channel creation: Riffle section at downstream tie in	$ -	CY	12741	$ 150.00	$ 1,911,111.11	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 660' length, 2' depth of riffle material.
Concrete Weir Installation	$ -	LF	200	$ 5,050.00	$ 1,010,000.00	Assume weir width of 4' and height of 9' (6' drop height + 3' foundation concrete). Assume reinforced marine concrete has a unit cost of $758/CY. Pile cost included.

Scope Item	Mead & Hunt Estimate Cost	Unit	WSP Quantity	WSP Unit Cost	WSP Opinion of Cost	WSP Notes
Installation of Fish Passage	$ -	VLF	9	$ 50,000.00	$ 450,000.00	Assume 6 FT drop from weir + 3 FT below downstream water elevation.
Miscellaneous Items						
Salvage Value	$ (45,075.00)	LS	1	$ (45,075.00)	$ (45,075.00)	Utilize Mead & Hunt opinion
Maintain recreation features	$ -	LS	1	$ -	$ -	4 Boat Launches, 1 Canoe Portage, 2 Fishing Access Locations, 3 Swim Areas, approximately 10 private boat docks. To be evaluated - no cost included.
Subtotal	**$31,882,259**				**$72,745,041**	
Contingency					$7,274,504.09	Assume 10% of subtotal excluding cost of contaminated sediment disposal.
Owner's Cost					$10,911,756.14	Assume 15% of subtotal excluding cost of contaminated sediment disposal.
Engineering and Permitting					$2,946,076.43	Assume 3.5% of subtotal excluding cost of contaminated sediment disposal + $400K for weir/fish ladder design.
Construction Management & Biological Monitoring					$1,454,900.82	Assume 2% of subtotal excluding cost of contaminated sediment disposal.
Total					**$95,332,278**	

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.
3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.
4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

Spillway and Spill Gates						
Demolish and remove spillway including concrete weir and apron: Reinforced concrete demolition	$ 2,000,360.00	CY	11630	$ 207.00	$ 2,407,410.00	M&H used a unit cost for this item that does not match the unit cost used for reinforced concrete demolition of other structures. $207/CY is the unit cost typically used for this item.
Remove gates	$ 6,600.00	Tons	30	$ 220.00	$ 6,600.00	Utilize Mead & Hunt opinion
Remove hoist rails/platform	$ 1,547.00	Tons	7	$ 221.00	$ 1,547.00	Utilize Mead & Hunt opinion
Remove hoists	$ 1,100.00	Tons	5	$ 220.00	$ 1,100.00	Utilize Mead & Hunt opinion
Earth Dam and Reservoir/River Channel						
Drain 1702-acre reservoir	$ 1,560,417.00	LS	1	$ 949,360.00	$ 949,360.00	Utilize Mead & Hunt opinion. Adjust WSP cost for intake stop log price. M&H used a unit cost for this item that does not match the unit cost used for other dams. $850/CY matches that of other dams.
Demolish/remove entire earth dam, core wall, and emergency spillway: Excavation	$ 2,956,918.00	CY	202000	$ 14.64	$ 2,956,918.00	Utilize Mead & Hunt opinion
Demolish/remove entire earth dam, core wall, and emergency spillway: Reinforced concrete demolition	$ 362,344.00	CY	1750	$ 207.00	$ 362,344.00	Utilize Mead & Hunt opinion
Demolish/remove entire earth dam, core wall, and emergency spillway: Sheet piling removal	$ 30,673.00	SF	13000	$ 2.36	$ 30,673.00	Utilize Mead & Hunt opinion
Remove accumulated sediments: Dam pilot channel dredging	$ 16,426,599.00	CY	1390991	$ 7.09	$ 9,862,126.19	Utilize M&H quantity and Kiewit unit cost.
Remove accumulated sediments: Reservoir dredging	$ 10,528,551.00	CY	1536080	$ 7.09	$ 10,890,807.20	Assumes dredging 200' wide main channel is re-established with limited dredging. Assume 1,485,000 CY (from M&H opinion) required to remove fine grain sediments and re-establish channel. Secondary tributary connections = 6,895 LF, assume 50' width dredged, 4' depth avg = 51,000 CY.
Remove accumulated sediments: Mobilization/Demobilization	$ 118,077.00	LS	1	$ 118,077.00	$ 118,077.00	Utilize Mead & Hunt opinion. M&H assume two different mobilizations because of depth of reservoir (>40') being greater than vertical reach of hydraulic dredge (35').
Contaminated Sediments - Removal	$ -	CY	0	$ 7.09	$ -	Low risk for contaminated sediments in this impoundment.
Contaminated Sediments - Disposal	$ -	Tons	0	$ 70.00	$ -	Low risk for contaminated sediments in this impoundment.
Seed former reservoir bottom	$ 1,781,624.00	AC	1503	$ 3,100.00	$ 4,659,300.00	Mead and Hunt unit cost seems low at about $1,185/acre. Only acreage outside of dredged channels will need to be seeded. Wet meadow seed mix will be approximately $3,240/AC, upland seed mixes will be slightly less.
Plant former reservoir bottom	$ -	AC	1503	$ 3,072.00	$ 4,617,216.00	Acreage outside of dredged channels. No quantity from M&H opinion. Assume 480 plants per acre at $6.40 per plant (#2 container, 1-2' high).
Apply Erosion Control Measures: Silt Fence	$ 13,790.00	LF	14500	$ 5.00	$ 72,500.00	Adjusted unit cost per similar projects.
Apply Erosion Control Measures: Rip Rap Protection	$ 1,769,586.00	CY	5000	$ 150.00	$ 750,000.00	Extra rip-rap for temporary placement for erosion control. Assume higher unit cost than M&H, but less quantity.
Bank Stabilization: Hard Structure	$ 1,769,586.00	LF	23830	$ 333.33	$ 7,943,253.90	52,680 LF main channel; 6,895 LF tributary tie-ins. Assume 3H:1V, assume 6' bank, 2' embedment max, 36" thickness OSO = 15" riprap, 2.22 CY/LF bank, $150/CY. Assume 20% hard channel structure banks for all banks.
Bank Stabilization: Live stakes and Jute Matting	$ 168,532.00	LF	95320	$ 54.33	$ 5,178,735.60	52,680 LF main channel, 6,895 LF tributary tie-ins. M&H erosion mat unit cost was low at $0.24/ SY. Assume 3H:1V, assume 3' bank (1.5' per LF), add 30% for jute mat for anchor, Jute Mat = $2.04/SY, Live stakes = $5.47/each, 4 stakes per SY, add .2 CY/LF riprap/reused cobble at $150/CY for jute mat anchor). Assume 80% of all banks will have this type of stabilization.
Reuse (grading) of non-contaminated excavated and dredged material	$ -	CY	3129071	$ 8.00	$ 25,032,568.00	Additional effort to grade/rework material excavated/dredged for specific habitat creation.
Grading & Surface Preparation/Amendments	$ -	AC	1503	$ 6,700.00	$ 10,070,100.00	Grading and reworking of newly exposed sediments within reservoir.

Scope Item	Mead & Hunt Estimate Cost	Unit	WSP Quantity	WSP Unit Cost	WSP Opinion of Cost	WSP Notes
Channel creation: Riffle section at downstream tie in	$ -	CY	15556	$ 150.00	$ 2,333,333.33	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 1050' length, 2' depth of riffle material.
Sea Lamprey Control/Fish Pass System	$ -	LS	1	$ 2,000,000.00	$ 2,000,000.00	To be evaluated. $2M placeholder.

Remove generators	$ 74,949.00	Tons	283	$ 265.00	$ 74,949.00	Utilize Mead & Hunt opinion
Remove cranes	$ 7,945.00	Tons	30	$ 265.00	$ 7,945.00	Utilize Mead & Hunt opinion
Remove diesel generator	$ 532.00	Tons	2	$ 266.00	$ 532.00	Utilize Mead & Hunt opinion
Remove fixtures	$ 1,324.00	Tons	5	$ 265.00	$ 1,324.00	Utilize Mead & Hunt opinion
Remove hoists	$ 2,394.00	Tons	9	$ 266.00	$ 2,394.00	Utilize Mead & Hunt opinion
Remove electrical equipment	$ 64,943.00	LS	1	$ 64,943.00	$ 64,943.00	Utilize Mead & Hunt opinion
Reinforced concrete/masonry demolition (spill tubes, intake/tailrace retaining walls, and aprons)	$ 2,463,938.00	CY	11900	$ 207.00	$ 2,463,938.00	Utilize Mead & Hunt opinion
Remove trash racks	$ 3,973.00	Tons	15	$ 265.00	$ 3,973.00	Utilize Mead & Hunt opinion
Remove valves	$ 1,059.00	Tons	4	$ 265.00	$ 1,059.00	Utilize Mead & Hunt opinion
Remove gates	$ 15,360.00	Tons	58	$ 265.00	$ 15,360.00	Utilize Mead & Hunt opinion
Spillway and Spill Gates						
Demolish and remove spillway including concrete weir and apron: Reinforced concrete demolition	$ 2,000,360.00	CY	11630	$ 207.00	$ 2,407,410.00	M&H used a unit cost for this item that does not match the unit cost used for reinforced concrete demolition of other structures. $207/CY is the unit cost typically used for this item.
Remove gates	$ 6,600.00	Tons	30	$ 220.00	$ 6,600.00	Utilize Mead & Hunt opinion
Remove hoist rails/platform	$ 1,547.00	Tons	7	$ 221.00	$ 1,547.00	Utilize Mead & Hunt opinion
Remove hoists	$ 1,100.00	Tons	5	$ 220.00	$ 1,100.00	Utilize Mead & Hunt opinion
Earth Dam and Reservoir/River Channel						
Drain 1702-acre reservoir	$ 1,560,417.00	LS	1	$ 949,360.00	$ 949,360.00	Utilize Mead & Hunt opinion. Adjust WSP cost for intake stop log price. M&H used a unit cost for this item that does not match the unit cost used for other dams. $850/CY matches that of other dams.
Demolish/remove portion of earth dam to create sufficient breach: Excavation	$ 208,960.00	CY	45305	$ 14.64	$ 663,265.20	Utilize M&H unit cost. Assume 3:1 slope from top of weir to top of existing earth dam embankment.
Demolish/remove portion of earth dam to create sufficient breach: Reinforced concrete demolition	$ 18,635.00	CY	392	$ 207.00	$ 81,144.00	Utilize M&H unit cost. Prorate M&H full removal quantity with partial removal of earth dam.
Demolish/remove portion of earth dam to create sufficient breach: Sheet piling removal	$ 307.00	SF	2912	$ 2.36	$ 6,872.32	Utilize M&H unit cost. Prorate M&H full removal quantity with partial removal of earth dam.
Remove accumulated sediments: Dam pilot channel dredging	$ 16,426,599.00	CY	1390991	$ 7.09	$ 9,862,126.19	Utilize M&H quantity and Kleast unit cost.
Remove accumulated sediments: Reservoir dredging	$ 10,528,551.00	CY	1536080	$ 7.09	$ 10,890,807.20	Assumes dredging 200' wide main channel is re-established with limited dredging. Assume 1,465,000 CY (from M&H opinion) required to remove fine grain sediments and re-establish channel. Not prorated because 6 FT weir will not create new impoundment. Secondary tributary connections = 6,895 LF, assume 50' width dredged, 4' depth avg = 51,080 CY.
Remove accumulated sediments: Mobilization/Demobilization	$ 118,077.00	LS	1	$ 118,077.00	$ 118,077.00	Utilize Mead & Hunt opinion. M&H assume two different mobilizations because of depth of reservoir (>40') being greater than vertical reach of hydraulic dredge (20').
Contaminated Sediments - Removal	$ -	CY	0	$ 7.09	$ -	Low risk for contaminated sediments in this impoundment.
Contaminated Sediments - Disposal	$ -	Tons	0	$ 70.00	$ -	Low risk for contaminated sediments in this impoundment.
Seed former reservoir bottom	$ 1,781,624.00	AC	1503	$ 3,100.00	$ 4,659,300.00	Mead and Hunt unit cost seems low at about $1,355/acre. Only acreage outside of dredged channels will need to be seeded. Wet meadow seed mix will be approximately $3.1K/AC; upland seed mixes will be slightly less.
Plant former reservoir bottom	$ -	AC	1503	$ 3,072.00	$ 4,617,216.00	Acreage outside of dredged channels. No quantity from M&H opinion. Assume 490 plants per acre at $6.40 per plant (40' container, 1-2' high).
Apply Erosion Control Measures: Silt Fence	$ 13,790.00	LF	14500	$ 5.00	$ 72,500.00	Unit cost adjusted per similar projects.
Apply Erosion Control Measures: Rip Rap Protection	$ 1,769,586.00	CY	5000	$ 150.00	$ 750,000.00	Extra rip-rap for temporary placement for erosion control. Assume higher unit cost than M&H, but less quantity.
Bank Stabilization: Hard Structure	$ 1,769,586.00	LF	23830	$ 333.33	$ 7,943,253.90	52,880 LF main channel; 6,895 LF tributary tie-ins. Assume 3H:1V, assume 6" bank, 2' embedment max, 30° thickness D30 = 15" riprap, 2.22 CY/LF bank, $150/CY. Assume 20% hand chemical structure banks for all banks.
Bank Stabilization: Live stakes and Jute Matting	$ 168,532.00	LF	95320	$ 54.33	$ 5,178,735.60	52,880LF main channel; 6,895 LF tributary tie-ins. M&H erosion mat unit cost was low at $0.24/ SY. Assume 3H:1V, assume 3' bank (1.5' per LF), add 30% to jute mat for anchor, Jute Mat = $2.04/SY, Live stakes = $5.47/each, 4 stakes per SY, add 2 CY/LF riprap/mossed cobble at $150/CY for jute mat anchor). Assume 80% of all banks will have this type of stabilization.
Reuse (grading) of non-contaminated excavated and dredged material	$ -	CY	2972376	$ 8.00	$ 23,779,008.00	Additional effort to grade/rework material excavated/dredged for specific habitat creation.
Grading & Surface Preparation/Amendments	$ -	AC	1503	$ 6,700.00	$ 10,070,100.00	Grading and reworking of newly exposed sediments within reservoir.

Scope Item	Mead & Hunt Estimate Cost	Unit	WSP Quantity	WSP Unit Cost	WSP Opinion of Cost	WSP Notes
Channel creation: Riffle section at downstream tie in	$ -	CY	14074	$ 150.00	$ 2,111,111.11	Excavation & dredging costs captured above. This item for placement of river rock through riffle section. Assume 200' width, 950' length, 2' depth of riffle material.
Concrete Weir Installation	$ -	LF	200	$ 5,050.00	$ 1,010,000.00	Assume weir width of 4' and height of 9' (6' drop height + 3' foundation concrete). Assume reinforced marine concrete has a unit cost of $780/CY. Pile cost included.
Installation of Fish Passage	$ -	VLF	9	$ 50,000.00	$ 450,000.00	Assume 6 FT drop from weir + 3 FT below downstream water elevation.
Miscellaneous Items						
Salvage Value	$ (62,930.00)	LS	1	$ (62,930.00)	$ (62,930.00)	Utilize Mead & Hunt opinion
Maintain recreation features	$ -	LS	1	$ -	$ -	4 Boat Launches, 1 Canoe Portage, 3 Marinas, 2 Fishing Access Locations, 3 Swim Areas, approximately 10 private boat docks. To be evaluated. No cost included.
Subtotal	**$39,236,291**				**$88,553,593**	
Contingency					$8,855,359.25	Assume 10% of subtotal
Owner's Cost					$13,283,038.88	Assume 15% of subtotal
Engineering and Permitting					$3,499,375.74	Assume 3.5% of subtotal + $400K for weir/fish ladder design.
Construction Management & Biological Monitoring					$1,771,071.85	Assume 2% of subtotal
Total					**$115,962,438**	

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.

4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

	Bank Stabilization - Hard Structure		$ 333.33	LF	8429	$ 2,809,771.90	Assume 3H:1V, assume 6' bank, 2' embeddment max, 30" thickness D50 = 15" riprap, 2.22 CY/LF bank, $150/CY
	Bank Stabilization - Live stakes and Jute Matting	$ 139,641.00	$ 54.53	LF	47767	$ 2,604,712.70	Assume 3H:1V, assume 3' bank (1.57 per LF), add 30% to jute mat for anchor, Jute Mat = $2.04/SY, Live stakes = $5.47/each, 4 stakes per SY, add .2 CY/LF riprap/reused cobble at $150/CY for jute mat anchor)
	Subtotal	**$9,653,696**				**$169,848,974**	
	Contingency					$3,705,949.09	Assume 10% of subtotal excluding cost of contaminated sediment disposal.
	Owner's Cost					$5,558,773.63	Assume 15% of subtotal excluding cost of contaminated sediment disposal
	Engineering and Permitting					$1,697,047.18	Assume 1.5% of subtotal excluding cost of contaminated sediment disposal + $400K for weir/fish ladder design.
	Construction Management & Biological Monitoring					$741,169.82	Assume 2% of subtotal excluding cost of contaminated sediment disposal.
	Total					**$181,551,814**	

Notes:
1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface
3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infractructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.
4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

	Salvage Value	$ (59,129.00)	$ (59,129.00)	LS	1	$ (59,129.00)	Zilliox Mead & Hunt opinion
	Subtotal	**$17,860,657**				**$42,397,781**	
	Contingency					$2,253,063.12	Assume 10% of subtotal excluding cost of contaminated sediment disposal.
	Owner's Cost					$4,429,594.69	Assume 10% of subtotal excluding cost of contaminated sediment disposal.
	Engineering and Permitting					$1,433,572.05	Assume 10% of subtotal excluding cost of contaminated sediment disposal + $400K for weir/fish ladder design.
	Construction Management & Biological Monitoring					$590,612.62	Assume 2% of subtotal excluding cost of contaminated sediment disposal.
	Total					**$51,804,623**	

Notes:
1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.
2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.
3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.
4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

Appendix A

A-3 ECONOMIC MODEL OUTPUTS (WORKBOOKS)

File:	01. Rogers - Financial Analysis CE Assumptions 6.1.2023 40%.xlsm
Client:	Consumers Energy
Project:	CEC Hydro Strategy Road Map
Content of this file:	Preliminary Financial Model to evaluate relicense and Surrender alternatives
Date submitted:	20-Jun-23
Instructions:	
	The outcome of this model is the Net Present Value (NPV) of the expected Expenses and Revenue Cashflows, in a long term life-cycle analysis of several scenarios of relicense or decommission of the plant.
	The inputs for the model are in tabs InpC, InpR, and Escalation assumptions are in the Esc Tab.
	- Only the Yellow cells can be modified
	The Cell F5 of the tab InpC is the selector of the scenario. The data in Column F show the data of the corresponding scenario, which is extracted from the data in Columns M to Q
	Lines 130 to 138 can be used to calculate NPVs based on considering variations to some key inputs (sensibilities)
	Similarly, data in the InpR tab is for all scenarios, but the only data used to calculate correspond to the data of the selected scenario
	The tab NPV shows the result of the selected scenario in cell H16. A macro named "Scenarios" can be run and it will populate the NPV of all scenarios in cells F20 to F29.
	The tab Assumptions and Key info detail some of the most relevant assumptions of the model. More assumptions are seen in the yellow cells of tabs InpC, InpR, Esc and Time.

Scenarios

There are three scenarios to relicense and three scenarios to decommission.

The relicense scenarios are: to upgrade the plant (increasing generation), to overhaul (major maintenance, minimal generation increase), and relicensing but not doing any kind of overhaul or upgrade.

The decommission scenarios are: Non-power operation, partial removal, and complete removal.

Timing

New License Term	50 Years
Relicense Studies start on year	2028
Upgrade/overhaul on year	2034

Duration of Decommission Period	between 1 to 5 years depending on the scenario
Decommission starts	year after license expires: 2035 or 2085

Upgrade and Overhaul scenarios - Capital costs

	Relicense 1 (Upgrade)	Relicense 2 (overhaul)	Relicense 3 (maintain)
Capital and maintenance projects needed to maintain the asset (LTFP)	X	X	X
Turbines Upgrades (increase generation)	X		
Capital Overhaul (minimal increase in generation)		X	

Relicense and maintain plant Costs

Assumes implementing certain projects identified in the Long Term Financial Plan that are needed to maintain the current operations, without the intent of increasing the generation, but assuming that the Plant will continue its current operation once the license renovation has been approved.

Decommission costs

Surrender 1 - Non-Power Operation	Surrender 2 - Partial Removal	Surrender 3 - Complete Removal
The existing water-impounding structures would remain intact. The electric generating units and auxiliary equipment would be disabled and laid-up in the powerhouse to prevent generation of electricity. The spillway operation would be modified to pass river flows and maintain the existing reservoir.	- Demolition and removal of specific elements of the project to drain the impoundment and establish a river channel through the project site. - Only the bulk of the embankment dam sections outside of the floodplain would be left intact. - Exposed sediments and shoreline would be stabilized and re-vegetated.	- Demolition and removal of all the dam's structures and result in draining of the impoundment and establishment of a river channel through the dam site. '- Removal of the earth dam sections, concrete spillway, powerhouse, tailrace and retaining walls, and all appurtenant structures. '- During controlled drawdown, hydraulic dredging would be performed to approximate the river's original meander to allow the river to reestablish its course through the reservoir.

Revenue

- Revenue has been considered as the product of the expected generation by the rate projection that Consumers Energy provided, it starts in 2023 at $60.70/MWh and decreases, reaching a value of $30.2908/MWh in the year 2049. The average rate of years (2045 to 2049 has been used for the projection of the subsequent years in the analysis.
- A sensitivity analysis has been performed to analyze the resulting NPV of the revenues considering an escalation of the rate at 3%.
- A Grant of $2.5 million (spread evenly between 2025-2027) has been assumed for the project on the relicense scenarios.

Escalation and discount rates

- Values from the LTFP have been discounted to 2022 Dollars at 7% for values at 2023 and 2024, and at 4% for values in years 2025 and beyond.
- Discount rate for NPV calculation is 7.5%

APPENDIX

B SITE SUMMARIES

APPENDIX B.1

Rogers Dam
FERC No. P-2451

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Three earth embankment dam sections (one section 48 feet high and two sections 40 feet high), each with a concrete core wall and totaling 600 feet long.
- A 40-foot-high, 156-foot-long concrete spillway with six steel radial gates, a defunct log chute, and a concrete-lined discharge channel extending approximately 100 feet downstream.
- A reservoir with a normal surface area of 449 acres at elevation 861.6 feet (U.S. Geological Survey [USGS] datum) and a gross storage of 4,678 acre-feet.
- Reservoir shoreline spans approximately 21.3 miles and contains an estimated 200+ private parcels with riparian frontage, Mecosta Township Ulrich Park, and two MDNR managed boat launches.
- A concrete-and-masonry powerhouse containing four generating units with a total installed capacity of 5,418 kilowatts (kW).
- A 20-foot-long concrete apron with retaining walls in the powerhouse tailrace.
- Associated appurtenant structures.

Relicensing

- Major license (referenced in License Order, subject to form L-3)
- Non-compliance allegations related to operations of Rogers to maintain run-of-river operations downstream of Croton so as not to require a gaging station upstream of Rogers dam.
- Operational compliance with run-of-river
- Sedimentation of upper end of reservoir
- Northern Long Eared Bat & Kerner Blue butterfly potential
- Moderate private development along shoreline

Future License Conditions

- Operations monitoring/automation
- Water quality monitoring
- RTE Species Management Plans
- Recreation enhancements
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- Historic Properties Management Plan

Risks to Operating under another 50-year License

- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled “Rogers Hydroelectric Dam 2021 Powerhouse Condition Assessment Results,” the interior of the powerhouse was given a rating of 'Green' for the main level, indicating that no major repairs will be needed for another 10 to 20 years, and a rating of 'Orange' for the lower levels, indicating that major repairs may be needed after another 1 to 3 years. The ‘Orange’ rating for the lower levels can be attributed to cracking and spalling of the columns on the fourth floor; it was recommended that these columns be repaired as soon as practical, and that sister columns be evaluated and installed in the interim. Because the extent of concrete cracking on the exterior of the Powerhouse is unknown, the exterior was given a rating of 'Orange;' it was recommended that a more detailed investigation is performed.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder Associates Inc. (Golder) on September 25 and 30, 2018, and consisted of the above-

water concrete features/structures (Downstream Left Embankment Retaining Wall, Downstream Right Embankment Retaining Wall, Downstream Powerhouse Pier, Left Spillway Abutment, Left Wing Wall/Abutment, Log Chute, Right Spillway Abutment, Right Wing Wall/Abutment, Spillway, Piers, and Weir, Upper Downstream Left Embankment Retaining Wall - Segment 1, Upper Downstream Left Embankment Retaining Wall - Segment 2, and Upstream Spillway Piers). The report for this condition assessment is dated May 14, 2019. The downstream left embankment retaining wall, downstream right embankment retaining wall, and Upper Downstream Left Embankment Retaining Wall - Segment 1 were rated 'BLUE' indicating that major repairs may be needed within 5 to 10 years. The rest of the structures mentioned here were rated 'GREEN' indicating that major repairs are not expected to be needed for about 10 to 20 years.

The concrete feature ratings were based on above-water observations only. It was recommended to perform an underwater investigation of each feature and adjusting the ratings accordingly.

Another report by Golder dated March 21, 2019 was prepared after performing a non-destructive visual condition assessment of the spillway abutment walls located downstream of the spillway structure and the spillway apron on August 9, 2018. The Spillway Abutment Right Wall sloping section (from Sta. 1+20 to 2+50) was given an "ORANGE" rating, indicating major repairs may be necessary after 1 to 3 years. The segment between Sta. 0+00 and 2+50 was rated 'YELLOW' indicating major repairs may be necessary after 3 to 5 years. The Left Wall footing (Sta. 0+00 to 2+50) was rated "BLUE" and the vertical portion of the Left Wall was rated "GREEN". These structures/features were not included in the May 14, 2019 report.

On August 6, 2019, Golder performed a separate Phase 2 non-destructive visual condition assessment on the spillway left and right abutment walls and apron. During this assessment, concrete coring activities on the right abutment wall and the left abutment wall footing were going on to help estimate the depth of concrete deterioration in support of the future spillway wall repair project. Golder conducted a second site visit on August 30, 2019. The summary of these assessments are contained in Technical Memorandum dated November 4, 2019. Based on the findings of this report, Apron Slabs 3, 4, and 6 were rated 'ORANGE' while Apron Slabs 1 and 2 were rated 'GREEN'.

DIVE INSPECTION

- May 13, 2021, Downstream Spillway Inspection
    - Large 10 ft x 30 ft scour depression d/s of sheet pile wall d/s of tailrace. Depression extends up to 6 ft below hard clay shelf along riverbank – with undermining of hard clay shelf.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require as significant amount of capital to implement. The exception to this relates to spillway remediation.

There is a recommendation that the stability analysis be updated and improved. If the analyses are still outstanding, it could lead to recommendations for remediation/upgrades to the project.

Current Remediation Projects in LTFP

- Unit 4 Generator Rewind – Capital
- Left Embankment Retaining Wall Replacement – Capital
- Middle Embankment Toe Reverse Filter Installation – Capital
- Right Downstream Retaining Wall Replacement – Capital
- Spillway Chamber Fill – Capital
- Spillway Gates 4, 5, and 6 Replacement – Capital
- Powerhouse Right and Left Embankment Retaining Wall Replacement – Capital
- Embankment Stabilization – Capital
- Apron Inspection (Only exists until new spillway is operational) – O&M
- Powerhouse Basement Concrete Repairs – O&M
- Powerhouse Original Flooring Concrete Repairs – O&M

Remediation Projects not in LTFP

- Core Wall Upgrades
- Head Gates Resealing
- Tailrace Concrete Repairs

FERC Required Spillway Projects (in LTFP)

PMF Project – Capital

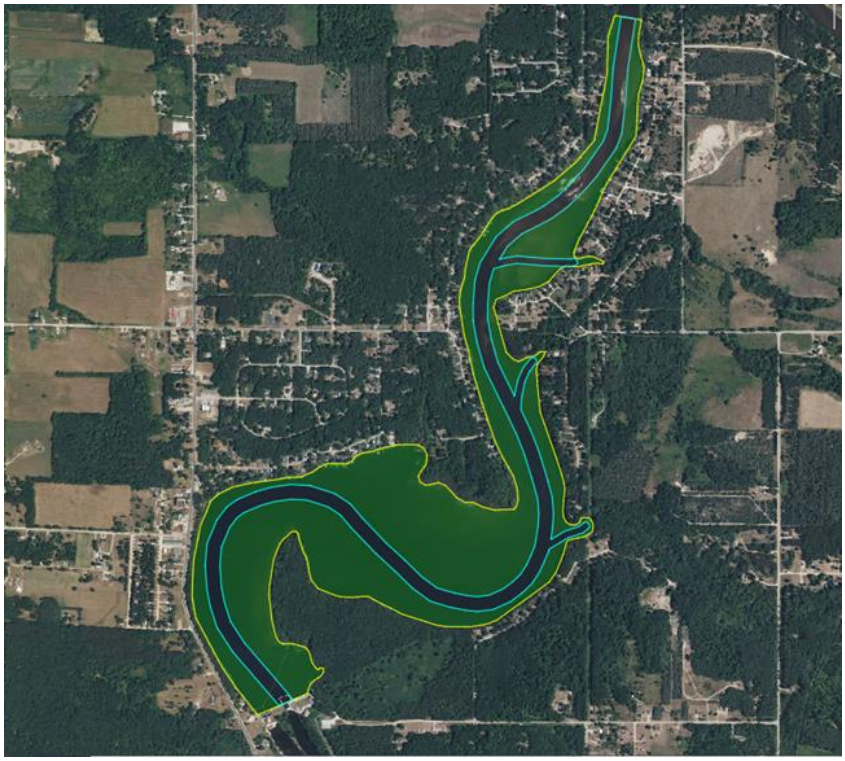
- The Muskegon River PMF Study resulted in a flood approximately 9,000 cfs higher than the current peak inflow at Rogers Dam. As a result, Rogers may not be able to pass the PMF. CEC plans to complete an options study to determine what improvements are required to pass the updated PMF at Rogers Dam (i.e. adding spillway bays, increasing core wall height, etc.) and plans to complete these improvements.

Generation

The Rogers development consists of 4 units with a calculated maximum generation capacity of 59,148 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 22,755 MWH, contributing 5% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 43,524 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)

Decommissioning (Partial)



- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates regulatory requirements for run-of-river operation coordination with Croton Dam
  - Eliminates risks of water quality violations in future years from elevated temperatures (not specifically an issue now but thermal loading in Rogers manifests in Hardy and Croton)
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.

- Auxiliary spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a SIGNIFICANT HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
  - 3 inhabited residential properties located along right bank between 300 FT to 700 FT downstream of dam
  - 10 inhabited residential properties located along left bank side at around 3,000 FT downstream of dam
  - S. State Street Bridge approximately 3,000 FT downstream of dam
  - Rt. 131 Bridge approximately 6,300 FT downstream of dam

- Key Considerations
  - Evaluate impact loss in reservoir has on neighboring properties with riparian access and recreational use/access.
    - There are a number (~200+) waterfront private parcels with riparian access that would likely experience shoreline retreat or change as a result of reservoir lowering. Evaluation of proposed conditions critical to early engagement with stakeholders.
    - Mecosta Township Ulrich Park.
    - MDNR manages Mecosta-Big Rapids Township Line Boat Launch & Rogers Height Boat Launch.
    - Evaluate options to perform additional dredging to create tributaries/canals to preserve water access to private properties and recreational facilities or construct new recreational facilities/parks within newly created bottomland/shoreline.
    - Evaluations should include temporary impacts and mechanisms to preserve recreational access (i.e. – during drawdown) and permanent impacts.
    - Coordination with MDNR on who would own and manage newly created bottom lands within the impoundment. MDNR focus on managing newly created bottom lands to restrict non-public development.
    - Under Mead & Hunt assumptions, approximately 499 acres converted from open-water impoundment to a 200' wide channel occupying approximately 75 acres.
  - Baseline studies including sediment characterization and bathymetry are critical to planning and alternative evaluation.
    - Potential contaminants have potential to drive costs considerable if removal is required.

- Sediment characterization would enable planning for future reuse of dredged sediment to create wetlands, transition areas and uplands within newly created riparian corridor.
- Updated bathymetry data would enable preliminary modeling of proposed conditions and impacts to neighboring stakeholders, recreational features and maintaining tributary connections.

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates regulatory requirements for run-of-river operation coordination with Croton Dam.
  - Eliminates risks of water quality violations in future years from elevated temperatures (not specifically an issue now but thermal loading in Rogers manifests in Hardy and Croton).
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.
- Key Considerations

- Evaluate impact loss in reservoir has on neighboring properties with riparian access and recreational use/access.
    - There are a number (~200+) waterfront private parcels with riparian access that would likely experience shoreline retreat or change as a result of reservoir lowering. Evaluation of proposed conditions critical to early engagement with stakeholders.
    - Mecosta Township Ulrich Park within buffer zone.
    - MDNR manages Mecosta-Big Rapids Township Line Boat Launch & Rogers Height Boat Launch.
    - Evaluate options to perform additional dredging to create tributaries/canals to preserve water access to private properties and recreational facilities or construct new recreational facilities/parks within newly created bottomland/shoreline.
    - Evaluations should include temporary impacts and mechanisms to preserve recreational access (i.e. – during drawdown) and permanent impacts.
    - Coordination with MDNR on who would own and manage newly created bottom lands within the impoundment. MDNR focus on managing newly created bottom lands to restrict non-public development.
    - Under Mead & Hunt assumptions, approximately 499 acres converted from open-water impoundment to a 200' wide channel occupying approximately 75 acres.
- Baseline studies including sediment characterization and bathymetry are critical to planning and alternative evaluation.
    - Potential contaminants have potential to drive costs considerable if removal is required.
    - Sediment characterization would enable planning for future reuse of dredged sediment to create wetlands, transition areas and uplands within newly created riparian corridor.
    - Bathymetry data would enable preliminary modeling of proposed conditions and impacts to neighboring stakeholders, recreational features and maintaining tributary connections.

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden.
    - Minimal changes to existing reservoir. No significant changes to existing environmental, socioeconomic, and recreational conditions.
- Cons/Risks
    - Legal liability associated with facilities/equipment surrendered in place.
    - Maintenance of facilities/equipment.
    - Potential for future takeover by other interested parties.
    - Requires capital improvements to ensure spillway is sufficient, maintained, and in compliance with all current and future regulations with respect to FERC and Michigan dam safety, fish passage, etc.

  - Does not address any currently identified deficiencies or safety/failure concerns.
  - Water quality (temperature and dissolved oxygen (DO)) downstream of Rogers may continue to be an issue and thermal loading in Rogers, although not elevating temperatures above state standards, does contribute to elevated temperatures downstream of Hardy and Croton.
- Key Considerations
  - Evaluate future & current regulatory requirements
  - Fish passage. Michigan DNR 2003 Muskegon River Management Plan, Management Action 13 discusses water quality and fisheries and specifically improving habitat by improving discharges. Management Actions 14 and 15 focus on fisheries protections and enhancements and include providing for fish passage by either dam removal or fish passage devices.
  - FERC & Michigan Dam Safety

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

APPENDIX B.2

Hardy Dam
FERC No. P-2452

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- A 114-foot-high and 2,600-foot-long earth embankment dam section with a concrete core wall.
- A 600-foot-long fixed-crest emergency spillway with a concrete-lined (for the upper 880 feet) discharge channel.
- A reservoir with a normal surface area of 3,902 acres at elevation 822.0 feet (USGS datum) and a gross storage of 134,973 acre-feet with depths varying 70'-100' within the channel that meanders through the impoundment.
- A steel-framed concrete-and-masonry intake structure with upper and lower intake openings.
- Three concrete penstocks to convey water from the lower intake opening to the intake tower.
- Three steel-lined concrete penstocks to convey water from the intake tower to the powerhouse.
- A steel-framed concrete-and-masonry powerhouse containing three generating units with a total installed capacity of 29,229 kW.
- 200-foot-long concrete apron with retaining walls in the tailrace. 200-foot-long concrete apron with retaining walls in the tailrace.
- Hydro plant is a peaking facility and regulates flow downstream to the Croton Dam.
- Associated appurtenant structures.

Relicensing Issues

- Major license (referenced in License Order, subject to form L-3)
- Peaking plant reregulated by Croton downstream
- WQ out of compliance for temp and dissolved oxygen (DO)
- Northern Long Eared Bat (Endangered), Tri-Colored Bat (Proposed Endangered) & Kerner Blue butterfly (Endangered), Monarch Butterfly (candidate) potential for studies and mitigation measures
- Listed on National Register of Historic Places (NRHP)
- Considerable Public Recreation Facilities
- Limited private property adjacent to shoreline

Future License Conditions

- Operations monitoring/automation
- Water quality mitigation/monitoring
- Recreation enhancements
- RTE Species Management Plans
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- Historic Properties Management Plan
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Loss of peaking operations
- Fish passage requirements
- Temperature and potentially DO exceedances
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled “Hardy Hydroelectric Dam 2021 Powerhouse Condition Assessment Results,” Powerhouse and Intake structures were each given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. Although no immediate major repairs are required, it was recommended that several features of the structures are monitored on a regular basis.

OTHER STRUCTURES

The Emergency Spillway, Splash Wall, Downstream Left Embankment Retaining Wall, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Upstream Embankment Retaining Wall, and Tipping Wall were inspected, and a Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed for each of these structures on September 25 and 28, 2018. Based on this assessment, the emergency spillway and the splash wall were rated as 'YELLOW' (3 to 5 years before major repairs or replacement is necessary). The rest of the structures mentioned here were generally found to be in good condition and were rated 'GREEN', with the recommendation that the joints in the left embankment retaining wall, right embankment retaining wall, and upstream embankment retaining wall be cleaned and sealed. Continuing monitoring the offset joint on both the left and right embankment retaining walls was also recommended to ensure movement is not taking place.

It should be noted that the condition assessment consisted of the above-water concrete features/structures and the concrete feature ratings were based on above-water observations only. It was recommended to perform an underwater investigation of each feature and adjust the ratings accordingly.

Another investigation was conducted by NDT Corporation using nondestructive sonic/ultrasonic Impact Echo (IE) measurements on the steel penstock liner on October 14th, 2020. Due to water leaks noticed externally at the butterfly valve section of this unit, it is suspected there may be voiding between the steel liner and grout behind the liner in the area of 10+/- feet upstream to 30+/- feet downstream of the butterfly valve on the right side of the spill tube.

Based on the Emergency Headgate Condition Assessment Report dated June 2019, the levels of corrosion, pitting, and section loss observed during the inspection were minor, and typically the remaining section measurements were equivalent to or greater than the nominal thickness of the members shown on the drawings. The bridge crane beams were observed to be in good condition and the paint system was intact. No significant defects, corrosion or section loss were observed, so a reduction in capacity should not be applied to the bridge crane beams.

DIVE INSPECTIONS

- May 10, 2022, Water Boils/Rip-Rap Area/West Sheet Pile Wall Inspection
    - 11 active water boils area of boil 'C' downstream (d/s) of tailrace. Pipe driven into ground near boil – no flow in pipe.
    - 15 active boils directly d/s of apron slab, near west sheet pile wall.
- July 23, 2021, Tailrace Inspection
    - 2 boils observed at east-west joint between draft tubes and apron slab – minimal flow through boils.
    - 1 concrete spall was observed on apron slab at east-west construction joint.
    - Weep holes in apron slab (4 weep holes) are active and generally show minimum flow, except for 1 weep hole in the middle slab closest to draft tube, which had 3.5 gpm flow.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement. The exception to this is the recommendation to repair or replace the Hardy auxiliary spillway as it was identified as presenting a dam safety concern. This project is underway and part of the LTFP.

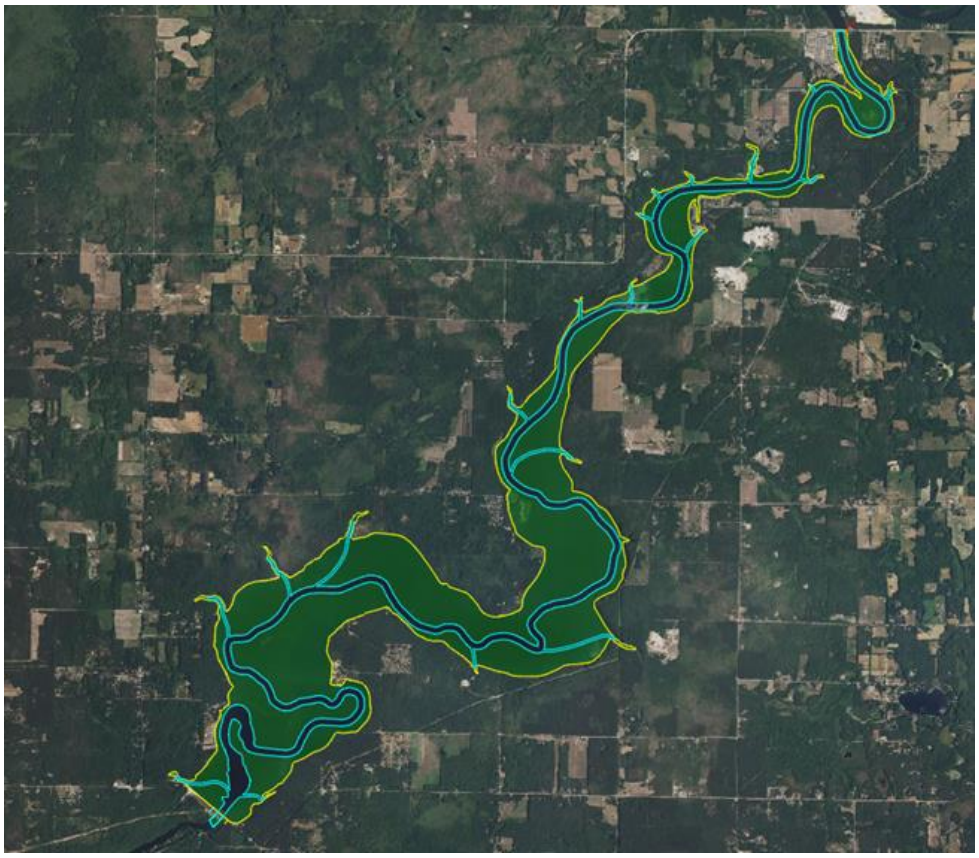
Current Remediation Projects in LTFP

- Right Embankment Toe Drain Header Replacement – Capital
- Left Embankment Toe Drain Header Replacement – Capital
- Canoe Portage Replacement- Capital
- Intake Tower Bridge Replacement – Capital
- Relief Well Area Reverse Filter – Capital
- Reverse Filter – Capital
- Units 1 & 2 Static Exciter Replacement – Capital
- Left and Right Tailrace Steel Sheet Pile Replacement – Capital
- Electrical Safety Project - Capital
- Penstock Expansion Joint Repacking and Refurbishment – O&M
- Stability Stress Analyses for STID Section 8.0 – O&M
- Intake Tower Brick Repair – O&M
- Unit 3 Runner Painting – O&M

Remediation Projects not in LTFP

- Penstock Lining and Cavitation Remediation
- Underwater Trash Gate Remediation
- Potential Upstream Timber Cribbing Remediation

FERC Required Spillway Projects (in LTFP)



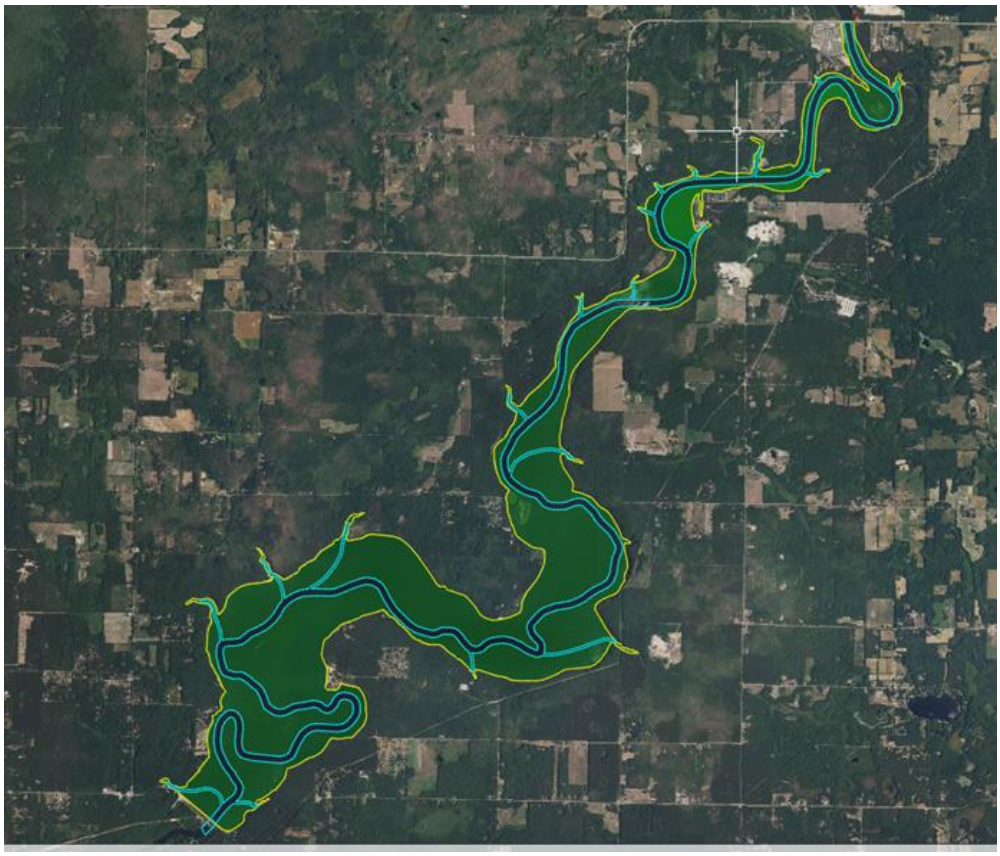
- Auxiliary Spillway Replacement – Capital
    - Findings from the Oroville Dam failure and site risk assessments have led to the determination that the current auxiliary spillway is deficient, deteriorated, and needs to be replaced. CEC plans to build a new auxiliary spillway on the right embankment, away from the powerhouse and spill tubes. This will bring the overall site risk below acceptable risk lines on the established risk map.
- Crest Roadway Replacement and Compaction – Capital
    - The earthen embankment at Hardy has a history of depressions and sinkholes that have formed along the crest of the embankment (generally from rotting or removal of railroad trestle used for original construction) as well loose embankment fill soils. CEC plans to remove the top five feet of embankment soil and replace it in one-foot-thick roller compacted lifts. This project would be completed simultaneously with the Splash Wall Replacement project.
- Splash Wall Replacement – Capital
    - The splash wall and sloping slab, upstream of the road, are deteriorated. The site risk assessment identified the hydraulic barrier (which includes the splash wall and sloping slab) as a component that could reduce risk at the site if improved. CEC plans to replace the deteriorated splash wall and sloping slab and improve the hydraulic barrier which would improve dam safety by addressing overtopping concerns and decreasing the potential for hydraulic loading of the embankment due to leaks through the hydraulic barrier.

Generation

The Hardy development consists of 3 units with a calculated maximum generation capacity of 284,700 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 107,495 MWH, contributing 24% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 145,118 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)

Decommissioning (Partial Removal)



- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Mitigates water quality and fish passage interests from Michigan DNR
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.
  - Auxiliary spillway and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.

- Water quality (temperature and DO) may still be out of compliance for cold water fisheries under License Article 405.
- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a SIGNIFICANT HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
  - Several (>30) inhabited residential properties along left bank between 800 FT to 7,000 FT downstream of dam
  - Hardy Dam Recreation Area located approximately 3,000 FT downstream of dam

- Key Considerations
  - Evaluate impact loss in reservoir has on neighboring properties with riparian access and recreational use/access.
    - The majority of reservoir riparian boundary is forested and owned by Consumers, but there are several parks, campgrounds (with dock space), marinas and boat ramps that would likely see significant shoreline retreat.
      - 5 major parks
      - 14 commercial marinas
      - Club and homeowner association uses
      - Individual and group docking sites.
    - Evaluations should include temporary impacts and mechanisms to preserve recreational access (i.e. – during drawdown) and permanent impacts.
    - Impoundment depths exceed 100' near the dam with much of the impoundment in the 70'-100'. Restoration options associated with decommissioning should develop alternatives to preserve a target depth/habitat and minimize dredging.
    - Coordination with MDNR on who would own and manage newly created bottom lands within the impoundment. MDNR focuses on managing newly created bottom lands to restrict non-public development.
    - Under Mead & Hunt assumptions, approximately 3,902 acres converted from open-water impoundment to a 200' wide channel occupying approximately 620 acres. Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir limits
  - Baseline Studies - Sediment Characterization & Bathymetry
    - Potential for contaminated sediment is significant influence on costs. Grain size distribution also critical for determining dredge volumes required.

- Bathymetry data critical to model propose conditions to develop preliminary plans and impacts to neighboring stakeholders, recreational features, and aquatic habitat.

Decommissioning (Full Removal)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Mitigates water quality and fish passage interests from Michigan DNR
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.
- Key Considerations
  - Evaluate impact loss in reservoir has on neighboring properties with riparian access and recreational use/access.

- The majority of reservoir riparian boundary is forested and owned by Consumers, but there are several parks, campgrounds (with dock space), marinas and boat ramps that would likely see significant shoreline retreat.
    - 5 major parks
    - 14 commercial marinas
    - Club and homeowner association uses
    - Individual and group docking sites.
- Evaluations should include temporary impacts and mechanisms to preserve recreational access (i.e. – during drawdown) and permanent impacts.
- Impoundment depths exceed 100' near the dam with much of the impoundment in the 70'-100'. Restoration options associated with decommissioning should develop alternatives to preserve a target depth/habitat and minimize dredging.
- Coordination with MDNR on who would own and manage newly created bottom lands within the impoundment. MDNR focus on managing newly created bottom lands to restrict non-public development.
- Under Mead & Hunt assumptions, approximately 3,902 acres converted from open-water impoundment to a 200' wide channel occupying approximately 620 acres. Significant planning and analysis required to determine how to manage existing recreational features.

- Baseline Studies - Sediment Characterization & Bathymetry
    - Potential for contaminated sediments is significant influence on costs. Grain size distribution also critical for determining dredge volumes required.
    - Bathymetry data critical to model propose conditions to develop preliminary plans and impacts to neighboring stakeholders, recreational features, and aquatic habitat.

License Surrendering (Non-Power Operation)

- Pros
  - Lower initial cost burden.
  - Minimal changes to existing reservoir. No significant changes to existing environmental, socioeconomic, and recreational conditions.
- Cons/Risks
  - Legal liability associated with facilities/equipment surrendered in place.
  - Maintenance of facilities/equipment.
  - Potential for future takeover by other interested parties.
  - Requires capital improvements to ensure spillway is sufficient, maintained, and in compliance with all current and future regulations with respect to FERC and Michigan dam safety, fish passage, etc. Does not address any currently identified deficiencies or safety/failure concerns.
  - Water quality (temperature and potentially DO) may still be out of compliance for cold water fisheries under License Article 405.
- Key Considerations
  - Evaluate future & current regulatory requirements
  - Fish passage. Should be designed with consideration to allow desirable species (Lake Sturgeon) and prevent non-desirable species (Sea Lamprey) from upstream migration in the event Croton Dam is also removed.
  - FERC & Michigan Dam Safety

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender. However, the large capital expenditure project of upgrading the spillway will make selling this Project difficult.

APPENDIX B.3

Croton Dam
FERC No. P-2468

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Two earth embankment dam sections (one section 53 feet high and one section 19 feet high), each with a concrete core wall.
- A 53-feet-high and 240-feet-long concrete spillway with eight steel radial gates, an overflow weir, and a concrete-lined discharge channel extending approximately 250 feet downstream with a 7-feet-high concrete weir located approximately 53 feet downstream.
- A reservoir with a normal surface area of 1,209 acres at elevation 722.0 feet (USGS datum) and a gross storage of 21,932 acre-feet.
- A concrete-and-masonry powerhouse containing four generating units with a total installed capacity of 7,473 kW.
- A 31-feet-long concrete apron with retaining walls in the tailrace.
- Associated appurtenant structures.

Relicensing Issues

- Major license (referenced in License Order, subject to form L-3)
- Downstream fish barrier (non-functioning fish ladder)
- Water Quality out of compliance; Upwelling system in place without success.
- Operational compliance (reregulation of Hardy) to run-of-river
- Northern Long Eared Bat (Endangered), Tri-Colored Bat (Proposed Endangered) & Kerner Blue butterfly (Endangered), Monarch Butterfly (candidate) potential for studies and mitigation measures
- Listed on National Register of Historic Places (NRHP)
- Notable number of shoreline property owners and recreation resources which would increase the nature of consultation during relicensing
- Impoundment is ongoing source of thermal pollution to downstream section of Muskegon River. Upwelling system installed in 2009 has not been successful in preventing temperature violations.
- Dam is critical physical barrier to preventing upstream migration of Sea Lamprey and protects roughly 200 miles of the Muskegon River. Dam turbine operation critical to downstream application of lampricide.
- Recreation
    - Public: portage at dam; Tailwater Park and East tailwater access, A.W. duChemin Park, and Croton Township Campground
    - Private: commercial marinas, restaurants, etc.
- Extensive Private residences and managed properties
    - ~500+ private properties on the impoundment with riparian access
    - 80% of impoundment shoreline privately owned

Future License Conditions

- Operations monitoring/automation
- Water Quality mitigation/monitoring
- Recreation enhancements
- RTE Species Management Plans
- Fish stocking/funding
- Fish Passage/Sea Lamprey exclusion
- Land/Shoreline Management
- Historic Properties Management Plan
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Fish passage requirement
- Temperature and potential dissolved oxygen (DO) mitigation
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements
- Outside the life expectancy of generating equipment

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Croton Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo," The interior and exterior powerhouse structure was given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. Although no immediate major repairs are required, additional maintenance and monitoring will be required in several areas to prevent the need for future repairs. In addition, it is recommended the crane runway capacity be reduced until the cracking observed at the brick columns is investigated further.

OTHER STRUCTURES

A condition assessment report was prepared by Golder (dated May 14, 2019). The assessment was performed on the following site features: Downstream Left Embankment Retaining Wall, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Downstream Spillway Apron (Exposed), Downstream Triangle, Fixed Crest Spillway – Bear Trap, Left Wing Wall/Abutment, Right Wing Wall/Abutment, Spillway Abutment, Spillway, Piers, and Weir, Training Wall, Upstream Powerhouse Piers, Upstream Spillway Piers, and Upstream Triangle.

The training wall was given YELLOW rating, which corresponds to 3 to 5 years before major repairs or replacement is necessary. The downstream right embankment retaining wall was given a BLUE rating, which corresponds to 5 to 10 years before major repairs or replacement is necessary. The other structures that were assessed were given a GREEN rating, which corresponds to 10 to 20 years before major repairs or replacement is necessary. Maintenance to the site over the years includes spillway modification, penstock repair and tailrace rehabilitation, and left embankment remediation.

DIVE INSPECTIONS

- November 16, 2021, Upstream Spillway Inspection:
  - Two vertical cracks along the concrete divider wall between the powerhouse and spillway.
  - One concrete spall along the western retaining wall.
- October 27, 2021, Downstream Spillway Inspection:
  - The concrete spillway slabs are separated to form upper and lower concrete slabs between the upstream/downstream bear trap construction joints. It is thought that the separation was from the original construction form board that has rotted away.

  - One open construction joint at the concrete divider wall between the spillway and powerhouse.
  - One concrete spall at the downstream end of the intermediate concrete scour slab.
- September 12, 2022, Upstream Powerhouse Inspection:
  - Two concrete spalls along the east concrete retaining wall.
  - Angle irons used for retaining the stop blocks up to 20% deteriorated.
  - One spall at concrete pier between bays 1 and 2.
  - One vertical crack at the west retaining wall.
- September 13, 2022, Downstream Powerhouse Inspection:
  - Two concrete spalls at Draft Tube Bay #4.
  - Zebra mussel shells covered the floor of Draft Tube #3 (2-5 ft thick).
  - One diagonal crack at west retaining wall.
  - Two open construction joints along the downstream concrete scour slab.
  - Once concrete spall at the concrete divider wall between powerhouse & spillway.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

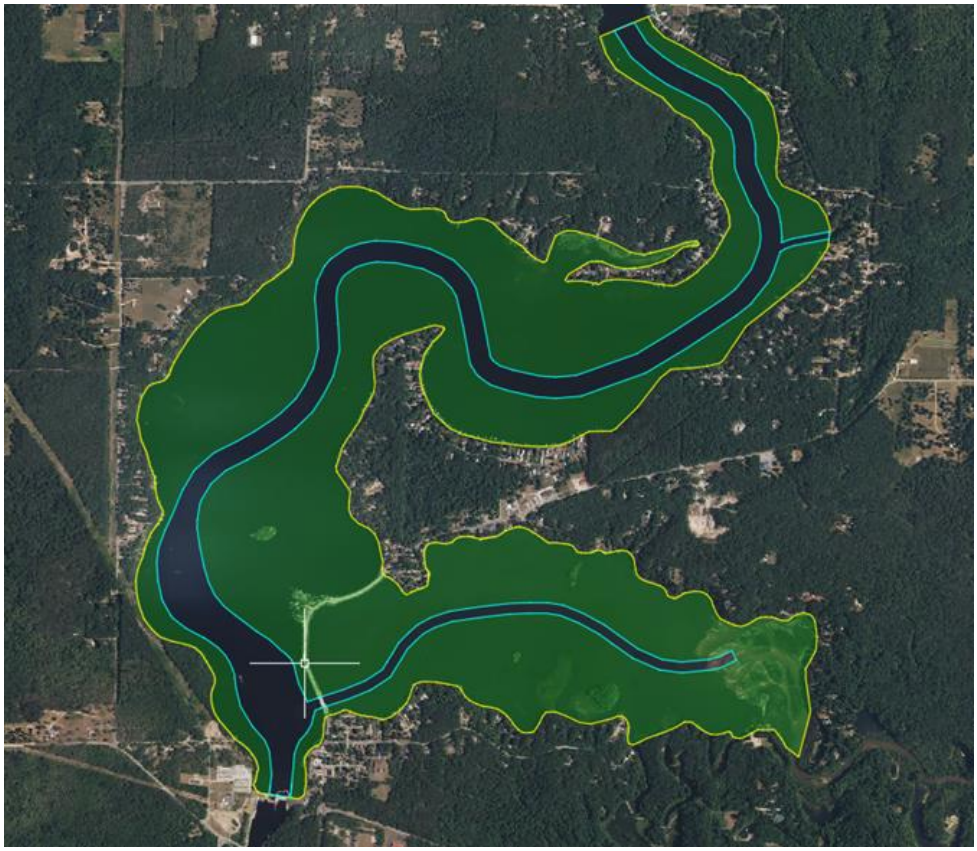
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement.

Current Remediation Projects in LTFP

- Unit 3 Overhaul – Capital
- Training Wall Replacement – Capital
- Spillway Apron Remediation Overlay - Capital
- Auxiliary Generator Replacement – Capital
- Units 1 and 2 Wicket Gate Replacement – Capital
- Units 3 and 4 Thrust Bearing Oil Cooler Replacement – Capital

Remediation Projects not in LTFP



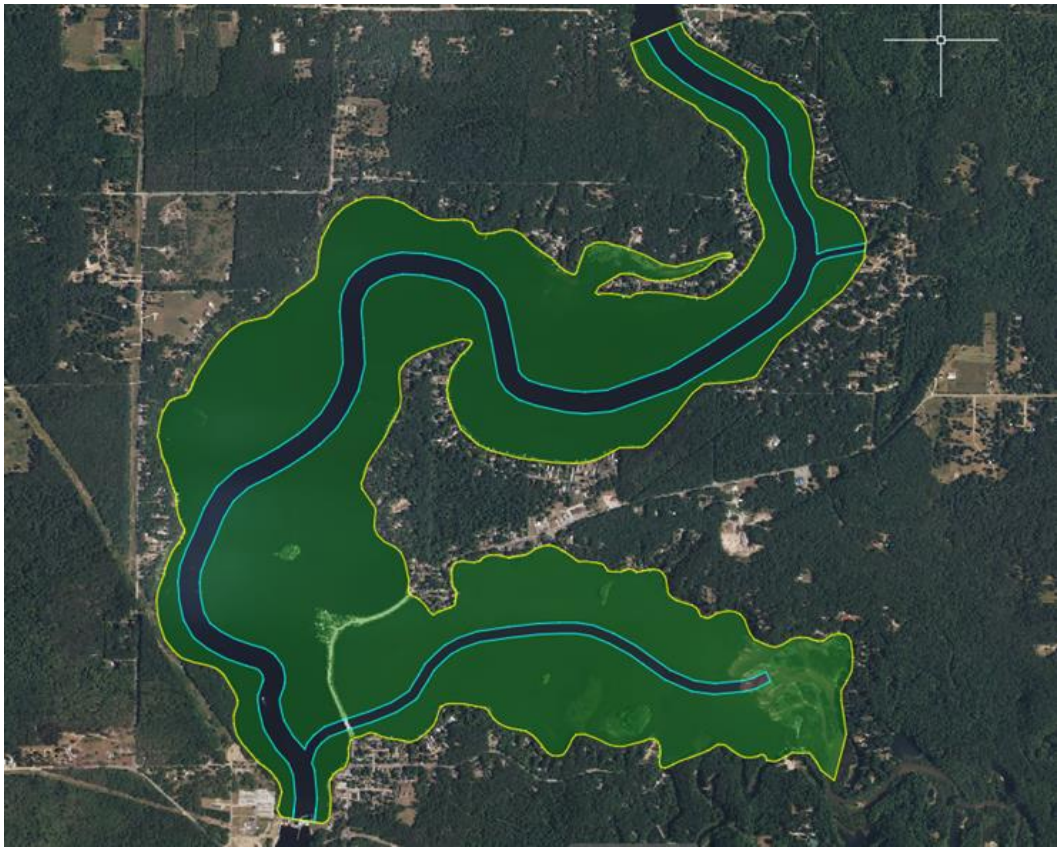
- Units 1 and 2 Steel Liner Remediation
- Headgate Tension Rod Replacement
- Penstock Floor Beam Concrete Remediation
- Penstock Concrete Erosion Remediation
- Dead Bay Leakage Remediation

Generation

The Croton development consists of 4 units with a calculated maximum generation capacity of 77,526 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 34,737 MWH, contributing 8% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 78,617 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)

Decommissioning (Partial)



- Pros
  - Reduces legal liability and maintenance required of the existing facilities.
  - Mitigates many of the regulatory requirements associated with the existing spillway & reservoir.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.
  - Spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
  - Water quality (temperature and potential DO may still be out of compliance for cold water fisheries under License Article 405.

- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a SIGNIFICANT HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
  - 1 inhabited residential property along left bank approximately 2,400 FT downstream of dam
  - Several (>30) inhabited residential properties along right bank between 4,800 FT to 12,500 FT downstream of dam
  - Croton Drive Bridge approximately 750 FT downstream of dam
  - Happy Campers Campground approximately 1,500 FT downstream of dam

- Key Considerations
  - Evaluate future use of newly created shoreline and bottomland within impoundment.
    - MDNR focus on managing newly created bottomlands to restrict non-public development.
    - Property loss value evaluations for loss in property value for private properties with diminished riparian access. (500+ properties, many with dock space)
    - Under Mead & Hunt assumptions, approximately 925 acres converted from open water impoundment to upland or wetland. Considerations for selective additional dredging to preserve channels in critical areas.
  - Sea Lamprey control and treatment
    - Hydroplant turbines are critical for mixing for lampricide for downstream treatment of Sea Lamprey. Consultation with MDNR on alternative methods recommended. Currently, treatment occurs every 2-4 years at a cost of approximately $1.1M per treatment.
    - Dam is critical physical barrier for blocking upstream migration of Sea Lamprey. The dam protects nearly 200 miles of the Muskegon River. Removal should consider newly constructed barriers to limit upstream migration in consultation with MDNR.
  - Baseline Studies - Sediment Characterization & Bathymetry
    - Potential for contaminated sediments are significant influence on costs. Grain size distribution also critical for determining dredge volumes required.
    - Bathymetry data critical to model propose conditions to develop preliminary plans and impacts to neighboring stakeholders, recreational features and aquatic habitat.

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates issues with water quality (temperature and potential DO)
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.

- Key Considerations
    - Evaluate future use of newly created shoreline and bottomland within impoundment.
        - MDNR focus on managing newly created bottomlands to restrict non-public development.
        - Property loss value evaluations for loss in property value for private properties with diminished riparian access. (500+ properties, many with dock space)
        - Under Mead & Hunt assumptions, approximately 925 acres converted from open water impoundment to upland or wetland. Considerations for selective additional dredging to preserve channels in critical areas.
    - Sea Lamprey control and treatment
        - Hydroplant turbines are critical for mixing for lampricide for downstream treatment of Sea Lamprey. Consultation with MDNR on alternative methods recommended.
        - Dam is critical physical barrier for blocking upstream migration of Sea Lamprey. The dam protects nearly 200 miles of the Muskegon River. Removal should consider newly constructed barriers to limit upstream migration in consultation with MDNR.
        - Barrier system should be installed to prevent upstream migration of invasive species (sea lamprey and round goby); refer to FishPass System example by Great Lakes Fishery Commission.
    - Baseline Studies - Sediment Characterization & Bathymetry
        - Potential for contaminated sediments are significant influence on costs. Grain size distribution also critical for determining dredge volumes required.
        - Bathymetry data critical to model propose conditions to develop preliminary plans and impacts to neighboring stakeholders, recreational features and aquatic habitat.

License Surrendering (Non-Power Operation)

- Pros
  - Lower initial cost burden.
  - Minimal changes to existing reservoir. No significant changes to existing environmental, socioeconomic, and recreational conditions.
- Cons/Risks
  - Legal liability associated with facilities/equipment surrendered in place.
  - Maintenance of facilities/equipment.
  - Potential for future takeover by other interested parties.
  - Requires spillway maintenance and compliance with all current and future regulations with respect to FERC, dam safety, fish passage, etc.
  - Does not address any currently identified deficiencies or safety/failure concerns.
- Key Considerations
  - Evaluate future & current regulatory requirements
    - Fish passage. Should be designed with consideration to allow desirable species (Lake Sturgeon) and prevent non-desirable species (Sea Lamprey) from upstream migration.
    - Water quality (temperature and potential DO)
      - Water quality may still be out of compliance for cold water fisheries under License Article 405.
    - FERC & Dam safety
    - Evaluate maintenance costs

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

APPENDIX B.4

Hodenpyl Dam
FERC No. P-2599

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Two, 80-foot-high earth embankment dam sections, each with a concrete core wall.
- An emergency overflow spillway at the north end of the north embankment dam.
- A reservoir with a normal surface area of 1,798 acres at elevation 809.0 feet (USGS datum) and a gross storage of 39,684 acre-feet.
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 13,884 kW.
- A 157-foot-long concrete tailrace with retaining walls.
- Associated appurtenant structures

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- USFS is a significant property owner adjacent to the Project with public amenities. USFS has mandatory conditioning authority under the Federal Power Act (4(e) measures) which FERC must accept as part of their license Order which makes USFS important stakeholder during relicensing.
- Water Quality out of compliance; Upwelling system in place without success.
- Run of river operations
- Sedimentation of upper end of reservoir

- Northern Long Eared Bat, Indiana Bat, and Tri-colored Bat (Endangered species mgmt.)
- Very limited private development along shoreline

Future License Conditions

- Operations monitoring/automation
- Water Quality mitigation/monitoring
- RTE Species Management Plans
- Recreation enhancements
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- Historic Properties Management Plan

Risks to Operating under another 50-year License

- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled “Hodenpyl Hydroelectric Dam 2021 Powerhouse Condition Assessment Results,” the powerhouse was given a rating of 'Green', indicating that no major repairs will be needed for another 10 to 20 years. It was recommended that cracked/spalled areas of concrete with exposed steel should be repaired. It was also recommended that several cracked features of the powerhouse are monitored on a regular basis, and any changes documented.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder on September 26, 2018 and consisted of the above-water concrete features/structures consisting of Asphalt-Lined Emergency Spillway, Downstream Powerhouse Piers and Abutments, East Wall, Upper Left Embankment Retaining Wall, Lower Left Embankment Retaining Wall, Right Embankment Retaining Wall Section, Upper Right Embankment Retaining Wall, Upstream Powerhouse Piers. The findings are summarized in a report dated May 14, 2019. All features/ structures that were assessed were given a ‘GREEN’ rating indicating that major repairs will not be needed for about 10 to 20 years. The concrete feature ratings were based on above-water observations only. It was recommended to perform an underwater investigation of each feature and to adjust the ratings and remaining life estimates accordingly.

A focused Spillway Assessment Report prepared by AECOM (dated December 21, 2017) indicates that based on field observations (performed on August 9 and 10, 2017) the emergency spillway structure was in satisfactory condition. No immediate corrective actions are required to protect public safety or the project works. However, updated stability analysis

for the emergency spillway concurrently with the updated embankment stability analysis is recommended by AECOM, along with other potential analyses related to the internal erosion potential failure mode in relation with the asphalt surfacing at the emergency spillway. In addition, continuing visual monitoring at the toe of the emergency spillway was recommended for the seepage observed through the cracks near the toe.

DIVE INSPECTIONS

- June 21, 2017, Tailrace Inspection
  - No defects
- June 20, 2017, Intake Structure Inspection
  - West section trash-rack steel at Bays #2 and #1 'knife-edged' with 5-10% deterioration.
  - Vertical concrete spall at construction joint between west wing wall and west retaining wall at bay #2 (54 inches tall, 15 inches wide, 10 inches deep), no exposed steel identified.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require as significant amount of capital to implement; however, the recommended review of rating curves, freeboard calculations and analyses of the right embankment could lead to recommendations for remediation/upgrades to the project.

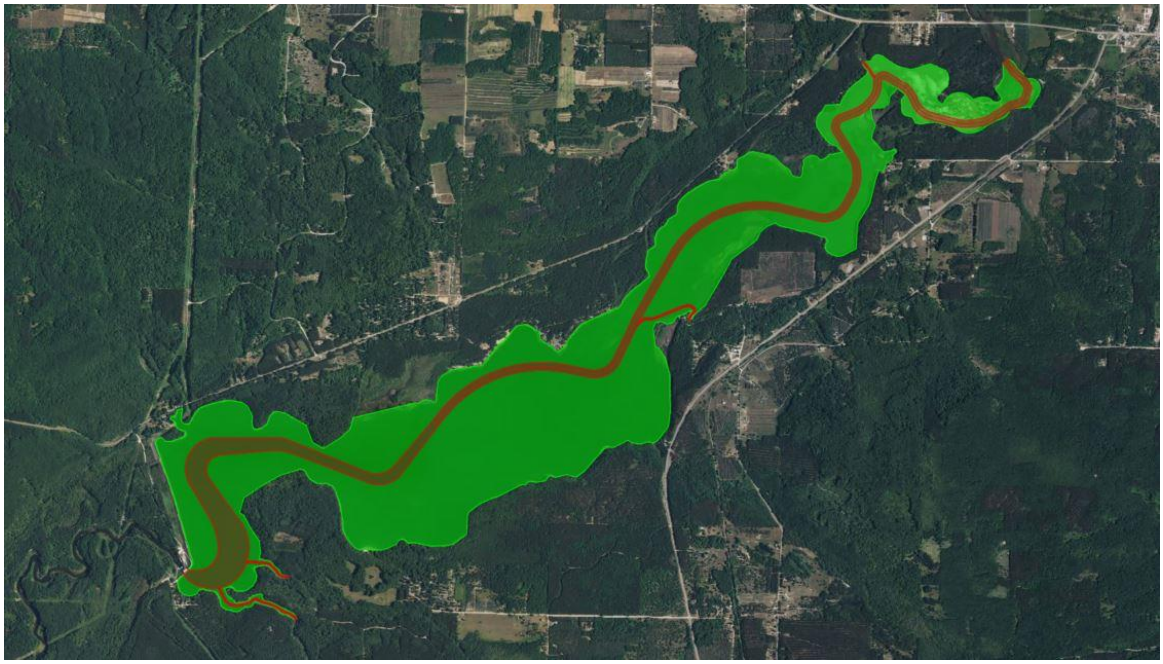
Current Remediation Projects in LTFP

- Unit 1 Generator Rewind – Capital
- Downstream Wall Replacement – Capital
- Spill Gate and Head Gate Hoist Replacement – Capital
- Left Abutment Cut-off Wall Replacement – Capital
- Core Wall Replacement - Capital
- Geotechnical and Stability Analyses – O&M

Remediation Projects not in LTFP

- Right Abutment Flow Remediation
- Unit 2 Overhaul
- Right Intake Wing Wall
- Powerhouse Structural Projects (Caterpillar Gates, Draft Tubes, etc.)

FERC Required Spillway Projects (in LTFP)

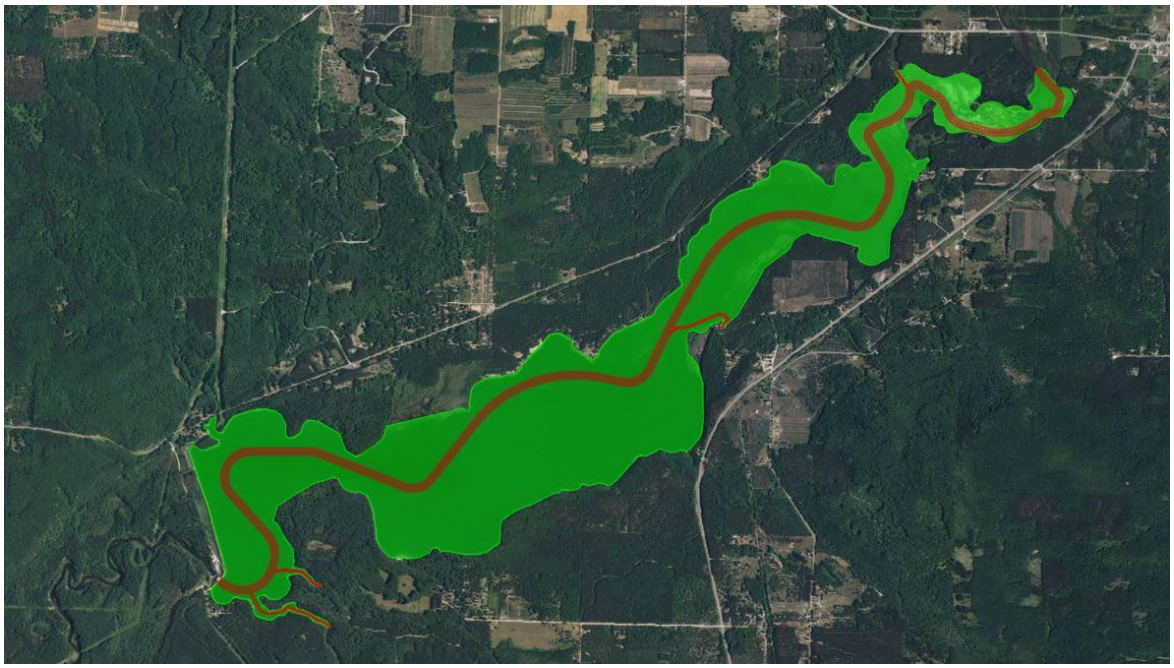


- Emergency Spillway Replacement – Capital
    - The existing emergency spillway would overtop during a PMF event, failure of the emergency spillway is likely due to lack of flow dissipaters and scour protection at the bottom, and risk drivers are associated with the emergency spillway. CEC plans to replace the emergency spillway by raising the crest, replacing the asphalt, and installing flow dissipators which would allow Hodenpyl Dam to pass the PMF without activating the emergency spillway and bring the overall site risk below the acceptable risk lines on the risk map.

Generation

The Hodenpyl development consists of 4 units with a calculated maximum generation capacity of 148,920 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 48,522 MWH, contributing 11% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 107,990 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
- Cons/Risks
  - Section 7 of the Endangered Species Act requires consultation with Fish & Wildlife Service, which may require other associated studies will be required because the Manistee River downstream of Tippy Dam is designated as a National Wild and Scenic River.
  - Features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Water quality (temperature and potentially dissolved oxygen (DO)) may still be out of compliance for cold water fisheries under License Article 405.
  - May also still cause sediment transport issues.
  - Public disapproval of this option due to its socioeconomic and recreational impact.

- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to agriculture, uninhabited buildings, structures, or township or county roads, where environmental degradation would be minimal, and where danger to individuals is slight or nonexistent. This opinion is based on the following considerations:
  - Manistee River trail suspension bridge approximately 2,200 FT downstream of dam
  - Transmission line monopoles on either side of bank 2,500 FT downstream of dam (likely at high enough elevation to be out of damage risk area)
  - Upper River Road boat launch along right bank approximately 3,400 FT downstream of dam
  - N Coates Highway bridge >6 miles downstream of dam
  - Upper River Road runs along right bank, but no structures nor inhabited homes on either side of downstream banks.

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.

- Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
    - Habitat can be restored along the entire footprint of the dam.
- Eliminates issues of water quality (temperature and potentially DO).
    - Recent letters filed with FERC allege the discharge from Hodenpyl Dam violates the 1992 Federal Energy Regulatory Commissions Settlement Agreement for temperature. Options to lower water temperatures are recommended to improve natural reproduction and recruitment of salmon populations, improve water quality, and reduce reliance on hatchery stocking. Currently the system is not self-sustaining as the Hodenpyl Dam is out of compliance more than half the time during June through September and 70% of the time over the entire year. Sections of the river upstream of Hodenpyl Dam have been evaluated for potential Arctic grayling reintroduction, current dam operation would negatively impact that.
- Eliminates sediment transport issues

- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Public disapproval of this option due to its socioeconomic and recreational impact.

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
        - Future repairs to dam structure.
    - Fish passage installation required.
    - Water quality (temperature and potentially DO) may still be out of compliance for cold water fisheries under License Article 405.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

APPENDIX B.5

Tippy Dam
FERC No. P-2580

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Two, 83-foot-high earth embankment dam sections, each with a concrete core wall.
- An 83-foot-high concrete spillway with four steel radial gates and a concrete-lined discharge channel extending approximately 240 feet downstream that includes a 24-foot-high concrete weir approximately 85 feet downstream of the radial gates.
- A reservoir with a normal surface area of 1,330 acres at elevation 687.4 feet (U.S. Geological Survey [USGS] datum) and a gross storage of 27,620 acre-feet.
- A concrete and masonry powerhouse containing three generating units with a total installed capacity of 14,255 kilowatts (kW).
- A 170-foot-long concrete-lined tailrace with retaining walls and downstream weir.
- Associated appurtenant structures.

Relicensing

- Major license (referenced in License Order, subject to form L-5)
- USFS is a significant property owner adjacent to the Project with public amenities. USFS has mandatory conditioning authority under the Federal Power Act (4(e) measures) which FERC must accept as part of their license Order which makes USFS an important stakeholder during relicensing.
- Northern Long Eared Bat, Indiana Bat, and Tri-colored Bat (Endangered species mgmt.) hibernating in spillway
- Wild and Scenic River downstream to Hwy 55 bridge
- Downstream fish barrier
- Buffers excluding development along shoreline

Future License Conditions

- Operations monitoring/automation
- Water Quality mitigation/monitoring
- RTE Species Management Plans
- Recreation enhancements
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- Historic Properties Management Plan

Risks to Operating under another 50-year License

- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled “Tippy Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo,” The interior and exterior of the powerhouse structure was given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. Although no immediate major repairs are required, additional maintenance and monitoring will be required in several areas to prevent the need for future repairs.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder on September 26, 2018 and consisted of the above-water concrete features/structures (Downstream Left Embankment Retaining Wall, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Downstream Spillway Apron (Exposed), Log Chute, Right

Wing Wall/Abutment, Spillway Abutment, Spillway Structural Walkway Deck, Spillway, Piers, and Weir, Training Wall, Upper Left Embankment Retaining Wall, Upstream Powerhouse Piers, and Upstream Spillway Piers). The findings were summarized in a report dated May 14, 2019.

The key findings from the Tippy Dam condition assessment identified three site features (the downstream left embankment retaining wall, downstream powerhouse piers, and log chute) that were rated as BLUE, which means 5 to 10 years before major repairs or replacement is necessary. In addition, cleaning and sealing of joints in the downstream right embankment retaining wall, exposed portion of the downstream spillway apron, and the spillway abutment is recommended. Periodic maintenance, including cleaning and sealing of the cracks and joints on the spillway, piers, and weir, is recommended as well. Golder also recommended continued monitoring of the upper left embankment retaining wall to ensure movement is not taking place. Other structures that were inspected during this condition assessment and are included in this report were given a GREEN rating (10 to 20 years before major repairs or replacement is necessary).

The concrete feature ratings were based on above-water observations only. Golder recommended performing an underwater investigation of each feature and to adjust the ratings and remaining life estimates accordingly.

DIVE INSPECTION

- August 1-2, 2017:
    - Zebra mussels completely covered the trash racks, piers, powerhouse walls, gated spillway, and left uncontrolled spillway. Trash racks were partially blocked by the Zebra mussels and debris.
    - All lower trash racks at Unit #3 were loose without bolts to hold them in place. Several trash racks at the upper portion were also loose without bolts.
    - There is an abandoned stop log in the chute for Unit #1 which could be moved but would need to be removed with a crane.
    - Unit #2 and Unit #3 each had small areas of scoured concrete, each 4 inches deep.
    - The Unit #1 deflector wall was undercut by 8 inches.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a “performance-focused” inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a “deep dive” into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

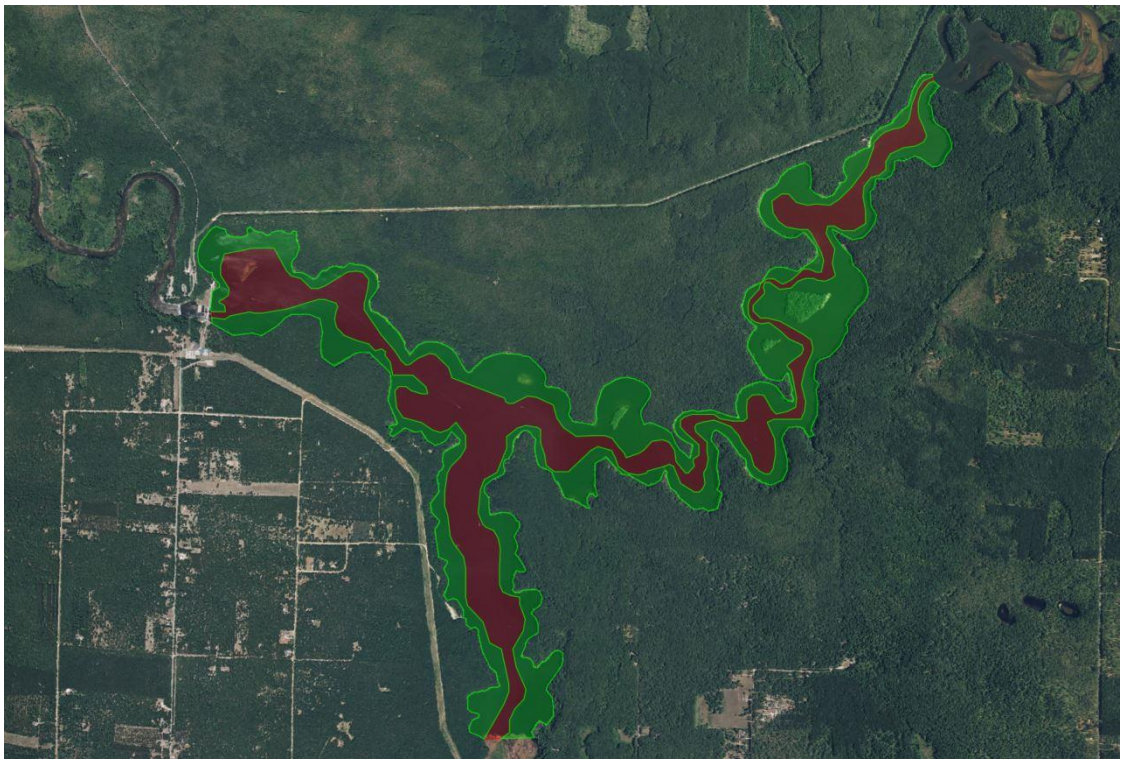
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement.

Current Remediation Projects in LTFP

- Downstream Filter Replacement – Capital
- Electrical Safety Upgrade – Capital
- Unit 1 Thrust Bearing Replacement – Capital
- Downstream Left Embankment Retaining Wall Remediation – O&M
- Downstream Powerhouse Pier Remediation – O&M
- Log Chute Repairs – O&M
- Spillway Chamber Inspection and Repairs – O&M
- Spillway Tumble Bay Weir Repairs – O&M
- SF6 Breaker Maintenance – O&M
- Powerhouse Apron Monitoring – O&M
- Intake Beam Repairs – O&M

Remediation Projects not in LTFP



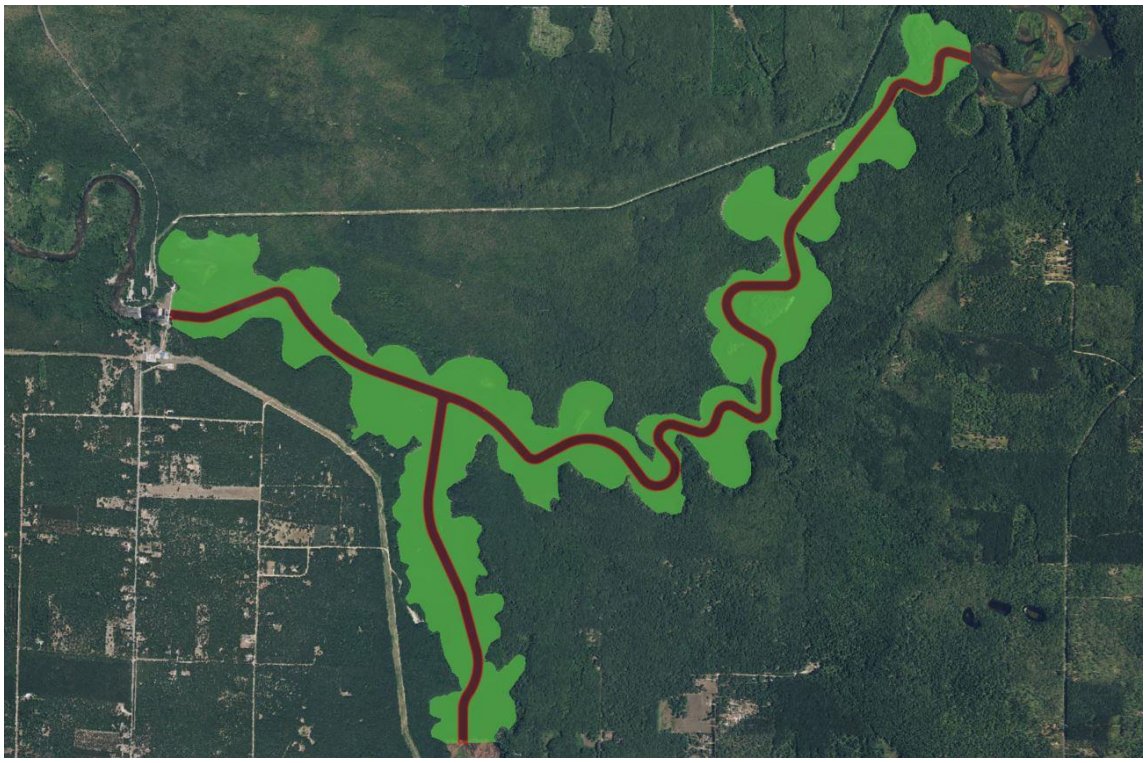
- Unit 2 Bearings
- Unit 1 Cavitation
- Scour Hole Repairs
- Left Tailrace Wall Replacement
- Penstock Concrete Repairs

Generation

The Tippy development consists of 3 units with a calculated maximum generation capacity of 176,076 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 62,108 MWH, contributing 14% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 119,059 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)

Decommissioning (Partial)



- Pros
  - The Tippy Dam is not currently meeting Article 405 discharge water temperature standards and has been determined to not be self-sustaining

- Cons/Risks
  - Tippy Dam is a barrier to invasive species traveling upstream from Lake Michigan.
  - Water quality (temperature and potentially dissolved oxygen (DO)) may still be out of compliance for cold water fisheries under License Article 405.
  - Tippy Dam has been identified as the only place in the upper Midwest where little brown bat populations have not been affected by White Nose Syndrome. It has not yet been determined why this is but any changes to the environment are highly discouraged. Researchers consider the site a valuable opportunity to determine why bat populations are protected there and studying it could lead to figuring out how to replicate conditions in areas that are affected. The powerhouse is a regionally important hibernacula to an estimated 10,000 little brown bats.

- Fish passage system should be designed with consideration to allow desirable species (Lake Sturgeon) and prevent non-desirable species (Sea Lamprey) from upstream migration.
- Tippy Dam is part of the Manistee River which is designated as a National Wild and Scenic River. A section 7 of the Endangered Species Act analysis is required for any changes to ensure the free-flow, water quality, and Outstanding Remarkable Values of the rivers are maintained.
- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
  - Tippy Dam Recreation Area < 500 FT downstream of dam
  - Tippy Dam Public Fishing Access 1,700 FT downstream of dam
  - 1 inhabited residential home >5 miles downstream of dam
  - N High Bridge Road Bridge >5.5 miles downstream of dam
  - Dilling Road runs along right bank for about first 4,000 FT downstream of dam

Decommissioning (Full)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
  - Habitat can be restored along the entire footprint of the dam.
  - Eliminates issues of water quality (temperature and potentially DO).
  - Recent letters filed with FERC allege the discharge from Hodenpyl Dam violates the 1992 Federal Energy Regulatory Commissions Settlement Agreement for temperature. Options to lower water temperatures are recommended to improve natural reproduction and recruitment of salmon populations, improve water quality, and reduce reliance on hatchery stocking. Currently the system is not self-sustaining as the Tippy Dam is out of compliance more than half the time during June through September and 70% of the time over the entire year. Sections of the river upstream of Hodenpyl Dam have been evaluated for potential Arctic grayling reintroduction, current dam operation would negatively impact that.
  - Eliminates sediment transport issues

- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Public disapproval of this option due to its socioeconomic and recreational impact.
  - Consideration of a barrier system to prevent upstream migration of invasive species (sea lamprey and round goby)

License Surrendering (Non-Power Operation)

- Pros
  - Lower initial cost than full removal or partial removal.
  - Maintain existing reservoir for recreational use. This option would likely be associated with the least public resistance as it would have the least immediate socioeconomic and recreational impact.
  - Fish passage not addressed but option could require installation of fish passage system; discontinuation of MDNR stocking.
  - Preserves the overwintering roosting habitat within Tippy spillway for bats.
- Cons/Risks
  - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
    - Future repairs to dam structure.
  - Fish passage installation required.

- Water quality (temperature and potentially DO) may still be out of compliance for cold water fisheries under License Article 405.
- Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

APPENDIX B.6

Mio Dam
FERC No. P-2448

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Two, 40-foot-high earth embankment dam sections, each with a concrete core wall.
- A 17-foot-high concrete spillway with one, 12.7-foot-high steel radial gate and a concrete-lined discharge channel extending approximately 220 feet downstream with a 6.5-foot-high concrete weir located approximately 45 feet downstream.
- A 530-foot-long auxiliary spillway located at the end of the south embankment dam.
- A reservoir with a normal surface area of 661 acres at elevation 962.6 feet (USGS datum) and a gross storage of 6,061 acre-feet.
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 3,885 kW. The powerhouse also contains two spill tubes used primarily as the service spillway. Only one spill tube is operational at this time.
- A 185-foot-long concrete tailrace with retaining walls.
- Associated appurtenant structures.

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- Known areas of groundwater contamination (PFAS) upstream of Mio and Upstream Air Force base is a Superfund site.
- USFS is a significant property owner adjacent to the Project with public amenities. USFS has mandatory conditioning authority under the Federal Power Act (4(e) measures) which FERC must accept as part of their license Order which makes USFS important stakeholder during relicensing.
- Historic Properties Management Plan (HPMP) – Historic Operators Homesite
- Water Quality out of compliance; MDNR Management Plan calls for removal of the dam. Upwelling system in place without success.
- Wild & Scenic River downstream to Alcona – popular paddling/float trip water trail (Blue water trail recreation)
- Recreation is important resource to region (fishing, paddling, campgrounds, etc.)
    - Camp 10 Boat Launch, Canoe portage at dam, Joseph Pillars Park, MDNR Mio Dam State Forest Campground, MDNR Mio Pond Access, Tailwater access, Scenic Overlook, Oscoda County Park, Rainbow Resort, Wayside Recreation Site, U.S. Forest Service.
- MNDNR lists Mio as priority for removal (only one on Au Sable) due to warming in the reservoir and its detriment to the cold-water fishery (and wild and scenic river designation to Alcona).

Future License Conditions

- Operations monitoring/automation
- Water Quality mitigation/monitoring
- Recreation enhancements
- RTE Species Management Plans
- Fish stocking/funding
- Fish Passage
- Land/Shoreline Management
- HPMP
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Formalization to run of river mode
- Fish passage requirements
- Temperature and dissolved oxygen (DO) exceedances
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Mio Hydroelectric Dam 2021 Powerhouse Condition Assessment Results," the powerhouse was given a rating of 'Green', indicating that no major repairs will be needed for another 10 to 20 years. It was recommended that steel support columns in the powerhouse are cleaned and recoated. It was also recommended cracks observed throughout the exterior and interior of the powerhouse are monitored on a regular basis.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder between May and June 2018 and consisted of the concrete features/structures (Auxiliary Spillway, Downstream Left Embankment Retaining Wall- Segment 1, Downstream Left Embankment Retaining Wall- Segment 2, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Log Chute, Spillway Abutment, Spillway Gate Piers and Concrete, Spillway/Powerhouse Apron, Spillway Structural Walkway Deck, Training Wall, Tumble Bay and Spillway, Upstream Apron, Upstream Left Wing Wall, Upstream Powerhouse Piers, Upstream Right Wing Wall) and spillway structural walkway. The findings are summarized in a report dated January 4, 2019. Based on this report, the training wall was rated as 'YELLOW' (3 to 5 years before major repairs or replacement is necessary). Three site features were rated as 'BLUE' (5 to 10 years before major repairs or replacement is necessary): segment 2 of the left embankment retaining wall, the downstream powerhouse piers, and the log chute. In addition, cleaning of the cracks and sealing the leaks at the base of the downstream slope of the auxiliary spillway was recommended. Golder recommended that the cause and extent of the horizontal cracks at the base of the powerhouse spanning the downstream powerhouse piers be investigated further to develop appropriate repairs, as well as monitoring of the joint between the left wing-wall and pier to confirm that no movement is taking place. Golder also recommended that further study be completed to assess whether the seepage noted during the dive inspection is leading to piping of the soils below and around the dam and the extent to which pore water pressures are generating uplift forces that pose a risk to the dam. Other structures that were assessed in this report were generally found to be in good condition and given a 'GREEN' rating.

An Auxiliary Spillway Assessment Report prepared by BARR (dated November 2017) includes the observations of a non-destructive visual inspection and summarizes the review of design data for the auxiliary spillway. The report also includes the results of the Potential Failure Modes Analysis (PFMA) focused on the auxiliary spillway. The auxiliary spillway was observed to be in good condition. There were localized areas of missing joint sealant and random tight cracking in the stilling basin apron slab and sloped baffle wall section slab. The ongoing inspections should continue to look for cracking, spalling, leakage, joint offsets, and missing joint sealant. The data review included review of the original design computations, soil boring logs in the area of the auxiliary spillway, related FERC correspondence, and construction drawings. The design was found adequate for the design assumptions used at the time of the original 1988 design. The 1988 design and 2009 repairs also appear adequate for the auxiliary spillway to safely pass the current Probable Maximum Flood (PMF) which is less than the PMF at the time of the original auxiliary spillway and repair design. As a result of the focused PFMA, no new monitoring methods or significant risk reduction measures were identified. The focused PFMA highlighted the following maintenance, surveillance, and risk reduction measures related to the auxiliary spillway.

DIVE INSPECTIONS

- June 22, 2021, Spillway Leak Inspection
    - An upstream dive inspection was conducted to assist CEC in identifying the source of the heavy flow through the tumble bay weep holes. Only a slight dye color was detected downstream during the dive inspection which occurred when placing the dye at the upstream end of the left cofferdam concrete seal.
- June 13 and 14, 2018 Part 12 Inspection
    - Upstream
        - Left wing wall and Unit 1 left pier wall exhibited spalling and up to 6 inches of separation between the two walls.
        - Cracking was found on the right powerhouse Unit 1 wall.
        - No significant findings were noted on the powerhouse Unit 2 walls, the right abutment wall, and log chute walls.
        - Right wing wall exhibited spalling, voids in the concrete, exposed rebar, and separation at the interface with the core wall.
        - Spalling and cracking exhibited on the concrete wall spanning between the right abutment wall and the Unit 2 pier wall.
    - Downstream
        - Right embankment retaining wall/spillway abutment wall exhibited spalling and a deteriorated joint at the interface with the weir which had cold water flowing through it.
        - Spalling was noted in the tumble bay.
        - Concrete damage in the freeze/thaw zone was noted on the weir. Exposed rebar and spalling were also exhibited at the weir/downstream apron interface.
        - Spillway apron exhibited spalling and broken concrete.
        - Training wall exhibited spalling with exposed wire mesh.
        - Left embankment retaining wall exhibited spalling and cracking with cold water flowing through.
        - No significant findings were noted on the Units 1 and 2 draft tubes and walls, with the exception of a hole in the concrete in the Unit 1 draft tube.
        - Tailrace apron exhibited spalling and open joints with cold water flowing through.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a “performance-focused” inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a “deep dive”

into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

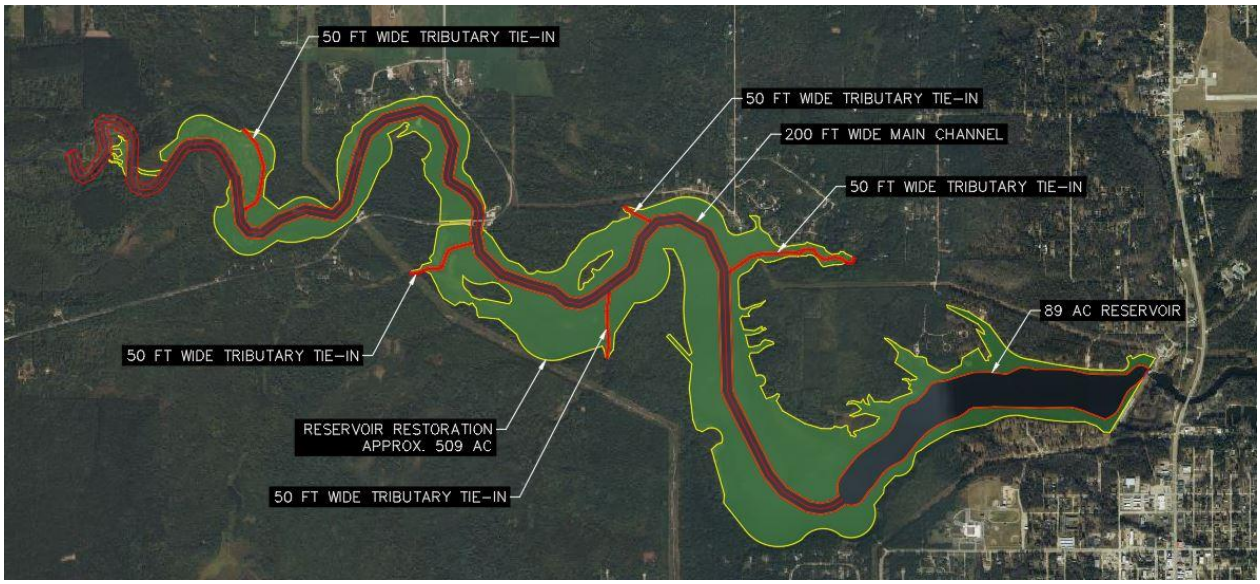
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement.

Current Remediation Projects in LTFP

- Unit 1 Wicket Gate Refurbishment – Capital
- Unit 2 Wicket Gate Refurbishment – Capital
- Electrical Safety Project – Capital
- Training Wall Replacement – Capital

Remediation Projects not in LTFP

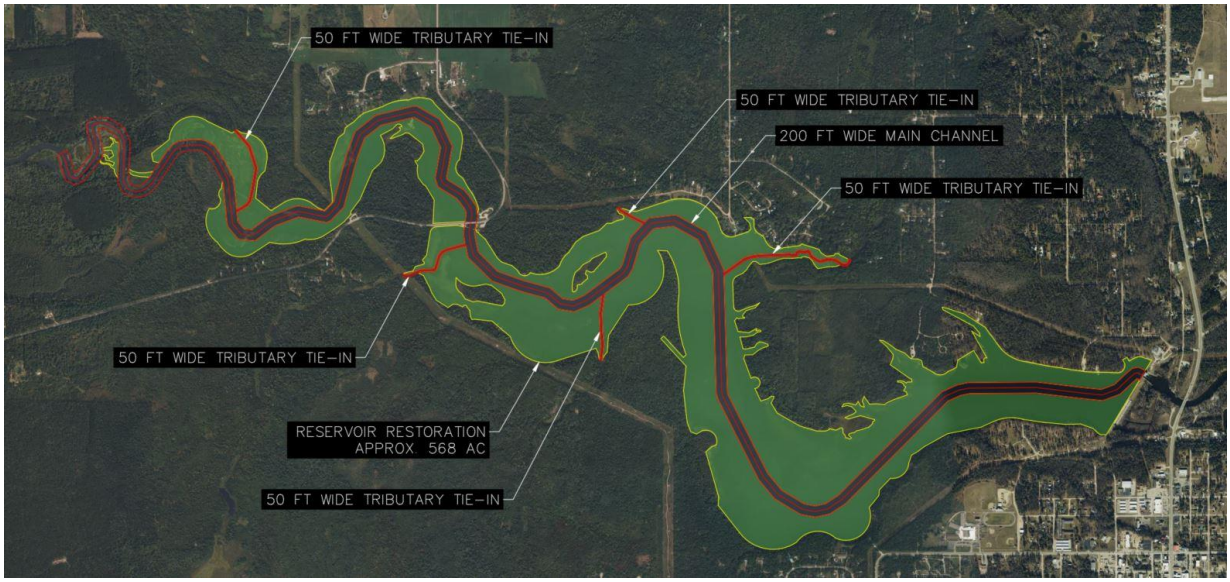


- Tumble Bay Leakage Through Concrete Beneath Spill Gates
- Powerhouse Armpit Leaks
- SF6 Breaker Maintenance
- Concrete Apron Joint Sealing Redo

Generation

The Mio development consists of 2 units with a calculated maximum generation capacity of 43,450 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 15,423 MWH, contributing 3% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 22,690 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
- Cons/Risks
  - Auxiliary spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Water quality (temperature and DO) may still be out of compliance for cold water fisheries under License Article 405.
  - May also still cause sediment transport issues. Mio Dam should be removed before all other downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Camp 10 Road Bridge partially blocking flow and causing upstream sedimentation may need to be replaced or have a widened underpass.

- Potential for contaminated sediment removal and disposal due to the upstream PFAS groundwater contamination from the Camp Grayling Superfund site. Sediment characterization required to determine distribution of potential contamination. Requires coordination with EPA to determine responsibility of cost burden.
- Public disapproval of this option due to its socioeconomic and recreational impact.
    - The Mio Dam also received a State Historic Marker in 2005, which may create additional resistance to the dam removal.
- Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir extents.
- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
    - No inhabited residential properties along riverbanks immediately downstream of dam
    - Pedestrian fishing pier approximately 550 FT downstream of dam along left bank
    - RT 33/Morenci Ave Bridge approximately 800 FT downstream of dam
    - Mio Au Sable River Launch approximately 1,350 FT downstream of dam along right bank (start of Wolf Creek pedestrian Trail along right bank)
    - Fed Trail 4367 Canoe Landing along left bank approximately 9,100 FT downstream of dam (start of Fed Trail along left bank).

Decommissioning (Full)

- Pros
    - Eliminates legal liability and maintenance of existing facilities.
    - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
    - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
    - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
        - Habitat can be restored along the entire footprint of the dam.
    - Eliminates issues of water quality (temperature and DO).
    - Eliminates sediment transport issues (if flow passage through Camp 10 Road Bridge is improved).
- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Mio Dam should be removed before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Potential for contaminated sediment removal and disposal due to the upstream PFAS groundwater contamination from the Camp Grayling Superfund site. Depending on the distribution of such contamination within the reservoir, this may be a significant cost burden.
    - Camp 10 Road Bridge/Boat Launch rebuild or under passage widening may add significant additional cost burden.

- Public disapproval of this option due to its socioeconomic and recreational impact.
    - The Mio Dam also received a State Historic Marker in 2005, which may create additional resistance to the dam removal.
- Significant planning and analysis required to determine how to manage existing recreational features.

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
    - Contaminated sediment removal and transport not required (contaminated sediments left in place)
- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
        - Future repairs to dam structure.
    - Fish passage installation required.
    - Water quality (temperature and potentially DO) may still be out of compliance for cold water fisheries under License Article 405. Significant costs may be required to bring the water temperature into compliance to support cold water fisheries.
        - As mentioned previously, an upwelling system was installed in Mio Dam, but the water quality is still out of compliance with high water temperatures. Additional features installed carry a similar risk of failure.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

APPENDIX B.7

Alcona Dam
FERC No. P-2447

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Two, 60-feet-high earth embankment dam sections, each with a concrete core wall
- A 250-feet-long emergency spillway located at the end of the east embankment
- A reservoir with a normal surface area of 1,006 acres at elevation 829.0 feet (USGS datum) and a gross storage of 12,547 acre-feet
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 7,905 kW
- A 135-foot-long concrete tailrace with retaining walls
- Associated appurtenant structures
- Recreation Facilities consist of Alcona Park, East & West Tailwater and canoe portage, and USFS Hwy 4001 Canoe Landing

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- No residential development around reservoir so the number of private landowner/stakeholders in licensing will be less than other sites
- USFS is a significant property owner adjacent to the Project with public amenities. USFS has mandatory conditioning authority under the Federal Power Act (4() measures) which FERC must accept as part of their license Order which makes USFS important stakeholder during relicensing.
- Recreation is important resource to region (Popular with canoe trips, camping, county park)
- Water quality out of compliance; MDNR Management Plan calls for removal of the dam
- Significant wild rice population (Tribal interest)
- Historic Properties Management Plan (HPMP) – three original operator structures

Future License Conditions

- Operations monitoring/automation
- Water Quality mitigation/monitoring
- Recreation enhancements
- RTE Species Management Plans
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- HPMP
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Fish passage requirements or mitigations
- Temperature and potentially dissolved oxygen (DO) exceedances or mitigations will be required
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements
- Ongoing maintenance of ageing equipment

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled “Alcona Hydroelectric Dam 2021 Powerhouse Condition Assessment Results,” the powerhouse was given a rating of 'Green',

indicating that no major repairs will be needed for another 10 to 20 years. Although no immediate major repairs are required, it was recommended that several features of the structures are monitored on a regular basis.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder Associates Inc. (Golder) on September 27 and 28, 2018 and consisted of the above-water concrete features/structures consisting of Downstream Powerhouse Pier, Abutments, and Walkway, Intake Deck Upstream Support Wall, Left Embankment Retaining Wall, Right Embankment Retaining Wall, Upper Left Embankment Retaining Wall, Upstream Powerhouse Piers. The findings are summarized in a report dated May 14, 2019. Based on this report, the intake deck upstream support wall was rated as 'BLUE' (5 to 10 years before major repairs or replacement is necessary). The other structures that were inspected during this condition assessment were rated 'GREEN'. The concrete feature ratings were based on above-water observations only. It was recommended to perform an underwater investigation of each feature and to adjust the ratings and remaining life estimates accordingly.

DIVE INSPECTIONS

- October 6, 2022, Unit #2 draft tube/east tailrace/downstream water boils Inspection
    - Bottom of upstream and downstream east retaining walls separated 30 inches – separation filled with stone/concrete blocks with water coming through.
    - Boils observed within 2 vertical construction joints along east retaining wall – 2 boils within each joint.
    - 2 concrete spalls observed in draft tube ceiling.
    - 3 concrete spalls along east apron slab with rebar visible.
    - 3 cracked out pieces of concrete observed along east apron with rebar visible.
    - Concrete spall observed on baffle wall weir.
    - East apron slab separated from baffle wall at several locations. Construction joint in east baffle wall is misaligned by 8 inches between east and west portions.
    - Apron slab downstreams of baffle wall spalled with rebar exposed.
    - 4 water boils are present downstream of the apron slabs.
- October 5, 2022, Unit #1 draft tube/west tailrace
    - 2 concrete spalls observed in draft tube bay for unit #1.
    - Separation of 3 vertical construction joints along west retaining wall with water boils.
    - 4 concrete spalls observed along west retaining wall.
    - 7 diagonal cracks observed along west retaining wall, with several water boils in cracks.
    - 6 concrete spalls observed along west concrete apron slabs .
    - Several apron slab horizontal joints are misaligned/offset, including joint between apron slabs and baffle wall.
    - 8 cracks present along west apron slab.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

CURRENT PART 12 RECOMMENDATIONS:

Due the on-going RIDM process for this project, FERC did not require a formal Part 12 IC inspection and report for 2021. However, an Informal Part 12 inspection was performed. The informal report was limited to a field inspection and a general review of the project data. Recommendations in the informal report cover only site condition issues and are relatively minor. The report did review recommendations from the previous Part 12 report. There is an outstanding recommendation that the existing stability analyses for the embankment and structures should be updated utilizing the current PMF. If this work has not been completed and there is no confirmation that the assets meet current required safety factors, it could lead to recommendations for remediation/upgrades to the project.

Current Remediation Projects in LTFP

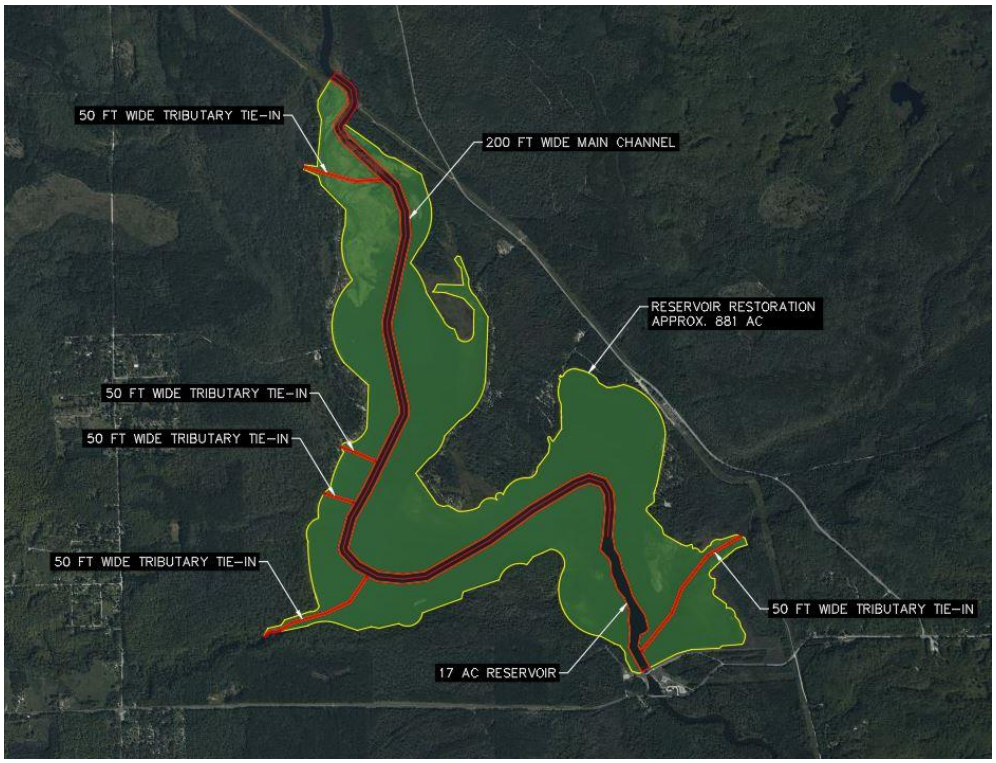
- Powerhouse Window Replacement - Capital
- Core Wall Remediation - Capital
- Intake Deck Upstream Support Wall - Capital
- Risk Informed Decision Making - Capital
- Trash Rack Ergonomics - Capital
- Electrical Safety Project - Capital
- Unit 1 Bearings & TGB Sleeve & Wicket Gates - Capital
- Relief Well Installation - Capital
- Units 1 & 2 Governor Replacement - Capital
- Artesian Design Study - Capital
- Units 1 & 2 Head Gate Replacement - Capital
- Left Driveway Retaining Wall Repairs - O&M
- Unit 1 Concrete Repairs (In Spiral Case) - O&M

Remediation Projects not in LTFP

- Head Gate Hoists – Capital

- Unit 2 Bearings & TGB Sleeve & Wicket Gates - Capital
- Unit 2 Overhaul (double acting Kaplan units)

FERC Required Spillway Projects (in LTFP)

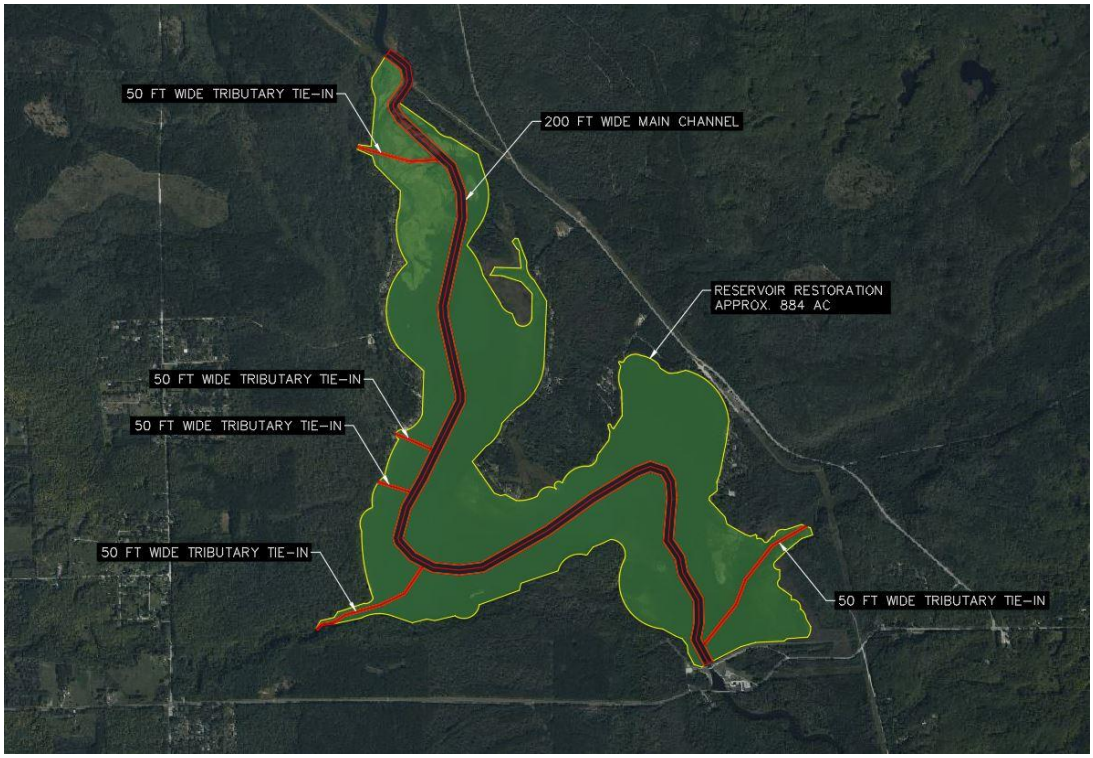


- RIDM Resolution (Auxiliary Spillway/Embankment Modifications/etc.) -Capital
    - The Alcona Risk Informed Decision Making Project identified the risk for auxiliary spillway erosion and subsequent failure exceeded the FERC tolerable risk guidelines. CEC plans to safely convey discharge from the auxiliary spillway across Bamfield Road and toward the forested area to the south by:
        - Installing scour protection along parts of the left non-core wall embankment upstream slope
        - Regrading about 360 feet of the left non-core wall embankment into a cone-shaped transition
        - Constructing a flow-guiding berm to Bamfield Road
        - Re-grading the auxiliary spillway channel to direct water toward the centerline of the spillway
        - Regrading Bamfield Road and constructing a scour-resistant cross to direct discharge across the road toward the Au Sable River

Generation

The Alcona development consists of 2 units with a calculated maximum generation capacity of 70,080 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 29,025 MWH, contributing 6% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 56,599 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.

- Cons/Risks
    - Emergency spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Water quality (temperature and potential DO) may still be out of compliance for cold water fisheries under License Article 405.
    - May also still cause sediment transport issues. Alcona Dam should be removed after the removal of the Mio Dam and before all other downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Potential for contaminated sediment removal and disposal due to the upstream PFAS groundwater contamination from the Camp Grayling Superfund site. Sediment characterization required to determine distribution of potential contamination. Requires coordination with EPA to determine responsibility of cost burden.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir limits.
    - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a SIGNIFICANT HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
        - 3 inhabited residential properties are located along right bank between 500 FT to 800 FT downstream of dam (along S Alcona Dam Road)
        - Bamfield Road Bridge is located approximately 500 FT downstream of dam
        - Bobcat Creek Park is located approximately 10,000 FT downstream of dam

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
  - Habitat can be restored along the entire footprint of the dam.
  - Eliminates issues of water quality (temperature and potential DO).
  - Eliminates sediment transport issues.

- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Alcona Dam should be removed after the removal of the Mio Dam and before all other downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Potential for contaminated sediment removal and disposal due to the upstream PFAS groundwater contamination from the Camp Grayling Superfund site. Depending on the distribution of such contamination within the reservoir, this may be a significant cost burden.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Significant planning and analysis required to determine how to manage existing recreational features.

License Surrendering (Non-Power Operation)

- Pros
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage improved, but requires installation of fish passage system; discontinuation of MDNR stocking.

- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
    - The non-power operation of the Alcona Dam may cost more than either of the removal options due to repairs that are needed for the earth dam and core wall, the tailrace, upslope protection, and a possible extension needed for the right embankment according to the Kiewit cost evaluation. The Kiewit cost evaluation also considers a widening of the auxiliary spillway which includes a flow guiding berm and regrading of Bamfield Road.
    - Water quality (temperature and potential DO) may still be out of compliance for cold water fisheries under License Article 405. Significant costs may be required bring the water temperature into compliance to support cold water fisheries.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

APPENDIX B.8

Loud Dam
FERC No. P-2449

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Two, 42-foot-high earth embankment dam sections, each with a concrete core wall.
- A 20-foot-high concrete spillway with three, 15.5-foot-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with a 6.5-feet-high concrete weir located approximately 45 feet downstream.
- A 100-feet-long emergency spillway.
- A reservoir with a normal surface area of 743 acres at elevation 742.6 feet (USGS datum) and a gross storage of 6,987 acre-feet.
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 4,000 kW.
- A 35-foot-long concrete apron in the tailrace with concrete retaining walls extending approximately 125 feet downstream.
- Associated appurtenant structures.
- Peaking plant operations (only on Au Sable)
- Significant amount of surrounding lands owned by USFS and Consumers; no development.
- Operationally linked with Five Channels Dam

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- Peaking plant reregulated by Five Channels Dam downstream
- USFS is a significant property owner adjacent to the Project with public amenities. USFS has mandatory conditioning authority under the Federal Power Act (4(e) measures) which FERC must accept as part of their license Order which makes USFS important stakeholder during relicensing. Sedimentation of upper end of reservoir
- Operators homes listed on National Register of Historic Places (NRHP)
- Considerable Public Recreation use on Au Sable River
- Majority public lands (USFS) and limited private property adjacent to shoreline
- Westgate, which is a popular overlook on M-65. The Iron Belle Trail/Iosco Exploration Trail will be using CE property near Westgate

Future License Conditions

- Operations monitoring/automation
- Recreation enhancements
- RTE Species Wildlife Management Plans
- Sediment Management
- Consult with USFS
- Land Management plan for buffer lands
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- Historic Properties Management Plan (HPMP)
- Retirement study
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Loss of peaking operations
- Fish passage requirements
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Loud Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo," The interior and exterior of the powerhouse structure was given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. Although no immediate major repairs are required, additional maintenance and monitoring will be required in several areas to prevent the need for future repairs. Additionally, it is recommended to repair the spalling with exposed rusting reinforcing steel above Unit 1 to prevent further deterioration.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder between June and July 2018 and consisted of the concrete features/structures (excluding the powerhouse) and spillway structural walkway. The findings were summarized in a condition assessment report for Loud Hydroelectric Dam dated January 4, 2019.

The key findings from the Loud Dam condition assessment identified two site features (embankment core wall section - above water, and training wall) that were rated as ORANGE (1 to 3 years before major repairs or replacement is necessary). One site feature (segment 2 of the downstream left embankment retaining wall) was rated as YELLOW (3 to 5 years before major repairs or replacement is necessary). In addition, periodic maintenance including cleaning and re-sealing of the joints is recommended for segment 1 of the downstream left embankment wall, log chute, and upstream spillway piers as soon as practicable. Golder recommends removing the vegetation overgrowth on the emergency spillway concrete sloping wall so that the remainder of the wall can be properly inspected. Golder also recommended refinishing the areas with protective coating loss on the spillway structural walkway to ensure corrosion does not reduce the design life of the structure. The underwater inspection of the right wing wall observed a 0.5-inch separation of the joint between the abutment and wing wall. Continued monitoring of the wing wall to abutment joint during routine dive inspections is recommended to confirm there is not future movement of the wall. Other structures that were inspected during this condition assessment and are included in this report were given a Green rating (10 to 20 years before major repairs or replacement is necessary).

DIVE INSPECTIONS

- Downstream Spillway, May 18, 2021:
    - 3 Diagonal cracks, 2 horizontal cracks, 2 vertical cracks, 4 concrete spalls, and 2 open vertical construction joints at north retaining wall.
    - 2 vertical cracks, 1 horizontal crack, 2 diagonal cracks, and 2 open vertical construction joints at divider pier between the spillway and powerhouse.
    - The downstream scour apron was separated from the divider wall at several locations by up to 8 inches. Several concrete spalls up to 5 inches deep were observed in the apron.
- Upstream Powerhouse & Spillway, May 19, 2021:
    - Lifting chains and connectors in the upstream spillway were deteriorated by up to 10%.
    - One horizontal crack was observed at the north retaining wall along the upstream spillway. One concrete spall was observed at the construction joint between the wing wall and the North retaining wall.

- Trash rack bars are deteriorated up to 10% throughout. Trash racks in Bay #3 are completely blocked with Zebra mussels. Bay 3 is a dead bay with not generating unit installed.
- One concrete spall at the pier between Bay #s 2 and 3.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

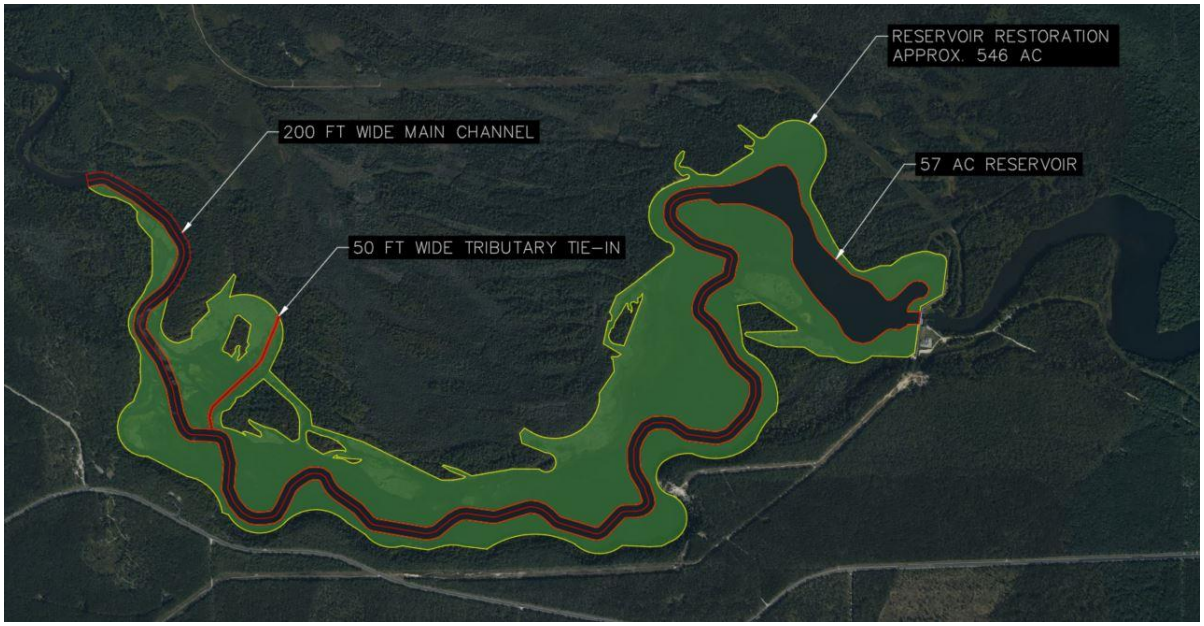
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement. The exception to this is the potential for repair of the core wall based on the results of the evaluation of survey data for ongoing movements, the repair of the left spillway retaining wall and the review of whether the emergency spillway is needed to pass the PMF.

Current Remediation Projects in LTFP

- Units 1 and 2 Governor Replacement – Capital
- Remote Spillgate Controls Installation – Capital
- Spillway Hoist Replacement – Capital
- Unit 1 Wicket Gate Replacement – Capital
- Unit 2 Wicket Gate Replacement – Capital
- Left Embankment Seepage Cutoff – Capital
- Electrical Safety Project – Capital
- Transformer Replacement – Capital
- Left Embankment Retaining Wall Replacement – Capital
- Unit 1 Generator Rewind – Capital
- Powerhouse Window Replacement – Capital
- Intake Deck Remediation – O&M

Remediation Projects not in LTFP



- Grass Lined Emergency Spillway Modification
- Units 1, 2, and 3 Headgate Replacement or Remediation
- Units 1 and 2 Concrete Repairs

Generation

The Loud development consists of 2 units with a calculated maximum generation capacity of 35,040 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 18,689 MWH, contributing 4% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 23,588 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)

Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - It is unlikely that the Loud Dam will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.

- Cons/Risks
    - Emergency spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - May also still cause sediment transport issues. The Loud Dam should be removed after removal of all upstream dams and before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir extents.
    - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a SIGNIFICANT HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
        - 3 residential homes along right bank approximately 1,100 FT to 1,500 FT downstream of dam

Decommissioning (Full)

- Pros
    - Eliminates legal liability and maintenance of existing facilities.
    - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
    - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
    - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
    - Habitat can be restored along the entire footprint of the dam.
    - Eliminates sediment transport issues
    - It is unlikely that the Loud Dam impoundment will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Loud Dam should be removed after all upstream dams and before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Significant planning and analysis required to determine

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
        - Future repairs to dam structure.
    - Fish passage installation required.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

APPENDIX B.9

Five Channels Dam
FERC No. P-2453

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Two, 45-feet-high earth embankment dam sections, each with a concrete core wall
- A 25-foot-high concrete spillway with three, 14.5-foot-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with an 8-foot-high concrete weir located approximately 60 feet downstream
- A reservoir with a normal surface area of 212 acres at elevation 715.0 feet (USGS datum) and a gross storage of 3,419 acre-feet
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 5,966 kW
- A 35-foot-long concrete apron in the tailrace with concrete retaining walls extending approximately 120 feet downstream
- Associated appurtenant structures
- Peaking operations

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- Peaking operations
- USFS is a significant property owner adjacent to the Project with public amenities. USFS has mandatory conditioning authority under the Federal Power Act (4() measures) which FERC must accept as part of their license Order which makes USFS important stakeholder during relicensing
- Considerable Public Recreation use on Au Sable River
- Majority public lands (USFS) and limited private property adjacent to shoreline
- Most visible dam on the Au Sable River due to the bridge crossing for M-65 at the dam. The old M-65 bridge is owned by MDOT and is key bridge for snowmobilers to cross the river.
- Five Channels Dam "Workers Camp" is listed on National Register of Historic Places

Future License Conditions

- Operations monitoring/automation
- Water quality monitoring
- Recreation enhancements
- RTE Species Wildlife Management Plans
- Sediment Management
- Consult with USFS
- Land Management plan for buffer lands
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Historic Properties Management Plan
- Retirement study
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Loss of peaking operations
- Fish passage requirements
- Temperature and dissolved oxygen (DO) exceedances
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Five Channels Hydroelectric Dam 2021 Powerhouse Condition Assessment Results," the powerhouse was given a rating of 'Green', indicating that no major repairs will be needed for another 10 to 20 years. It was recommended that exposed reinforcing steel observed near one of the units be repaired to prevent further deterioration. It was also recommended that cracking and spalling observed throughout the exterior and interior of the powerhouse are monitored on a regular basis.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder between June and August 2018 and consisted of the concrete features/structures (Downstream Left Embankment Retaining Wall, Downstream Powerhouse Apron, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Log Chute, Spillway Abutment, Downstream Spillway Apron, Spillway Structural Walkway Deck, Training Wall, Tumble Bay and Spillway, Upstream Left Wing Wall, Upstream Powerhouse Piers, Upstream Right Wing Wall, Upstream Spillway Piers) and Spillway Structural Walkway. The training wall was rated as 'YELLOW' (3 to 5 years before major repairs or replacement is necessary). Another site feature, the log chute, was rated as 'BLUE' (5 to 10 years before major repairs or replacement is necessary). In addition, biennial dive inspections of the downstream powerhouse apron and right wing-wall are recommended for continued monitoring. Golder recommended refinishing of areas with loss of protective coating on the spillway structural walkway deck to ensure corrosion does not reduce the design life of the structure. It is also recommended to perform periodic maintenance including cleaning and sealing of the joints as soon as practicable. Other structures that were inspected during this condition assessment and are included in this report were generally found to be in good condition and given a 'GREEN' rating.

DIVE INSPECTIONS

- Upstream Spillway and Powerhouse, July 14, 2021:
    - Spall on concrete on right side of divider pier between spillway and powerhouse.
    - Spill bays 1 through 3 exhibited no defects however the cotter keys need replacing.
    - Open construction joint (up to 3 inches wide) with sediment coming through at the bottom at the intersection between right wing wall and retaining wall.
    - Upstream left wing wall and Bays 1 through 3 trash racks exhibited no defects.
    - Upstream left retaining wall exhibited vertical cracks, 2 concrete spalls, and a vertical open construction joint between the retaining wall and the wing wall.
    - Spall on right side of divider pier between powerhouse and spillway.
- Downstream Powerhouse and Spillway, July 15 and 19, 2021:
    - Spall on concrete on left tailrace retaining wall.
    - No defects exhibited in draft tube Bays 1 and 2 but a horizontal concrete spall was exhibited on the left side of the divider pier between Bays 2 and 3.
    - No defects exhibited in the log chute.

- An open construction joint was exhibited on the downstream divider pier between the powerhouse and spillway.
- Minor undermining of the powerhouse concrete apron slab was exhibited downstream of draft tube 2 however no concrete defects were noted.
- No defects were exhibited on the spillway downstream right retaining wall and weir wall.
- Cracks, spalls, and an open vertical construction joint were exhibited on the right side of the divider pier between the spillway and powerhouse.
- No significant defects were exhibited downstream of the spillway concrete scour apron however 1 spall was exhibited adjacent to a construction joint.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

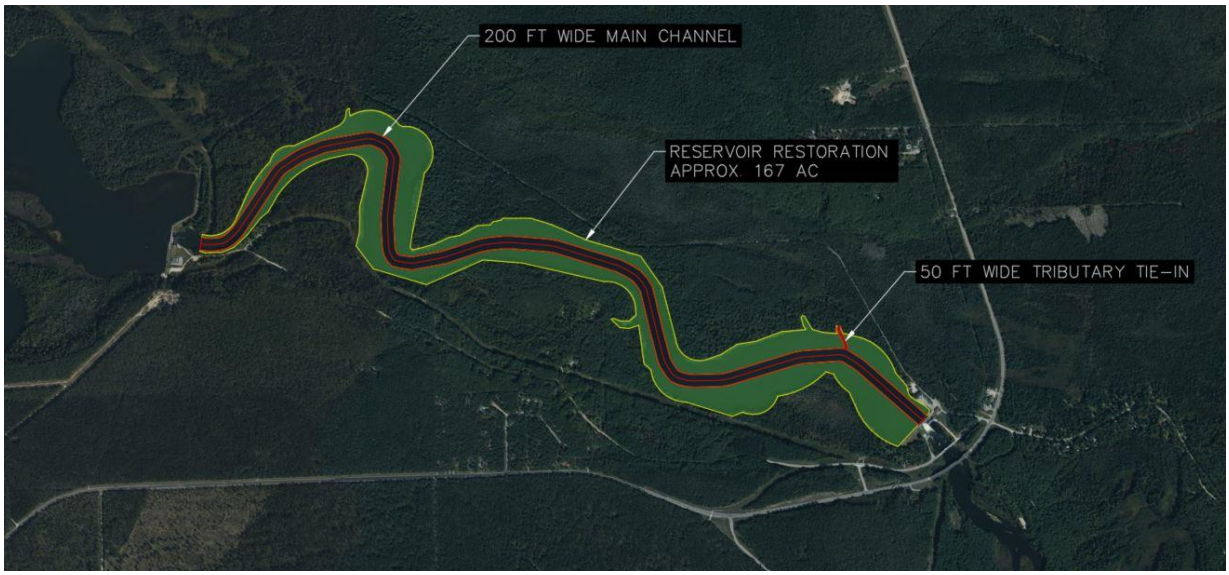
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement.

Current Remediation Projects in LTFP

- Remote Spillgate Controls Installation – Capital
- Unit 1 Wicket Gate Refurbishment – Capital
- Unit 2 Wicket Gate Refurbishment – Capital
- Dead Bay and Log Chute Replacement – Capital
- Headgate Replacement – Capital
- Spillway Hoist Replacement – Capital
- Training Wall Replacement – Capital
- Trash Rack Ergonomics Project - Capital
- Intake Deck Concrete Repairs – O&M
- Left Embankment Stability Study – O&M

Remediation Projects not in LTFP

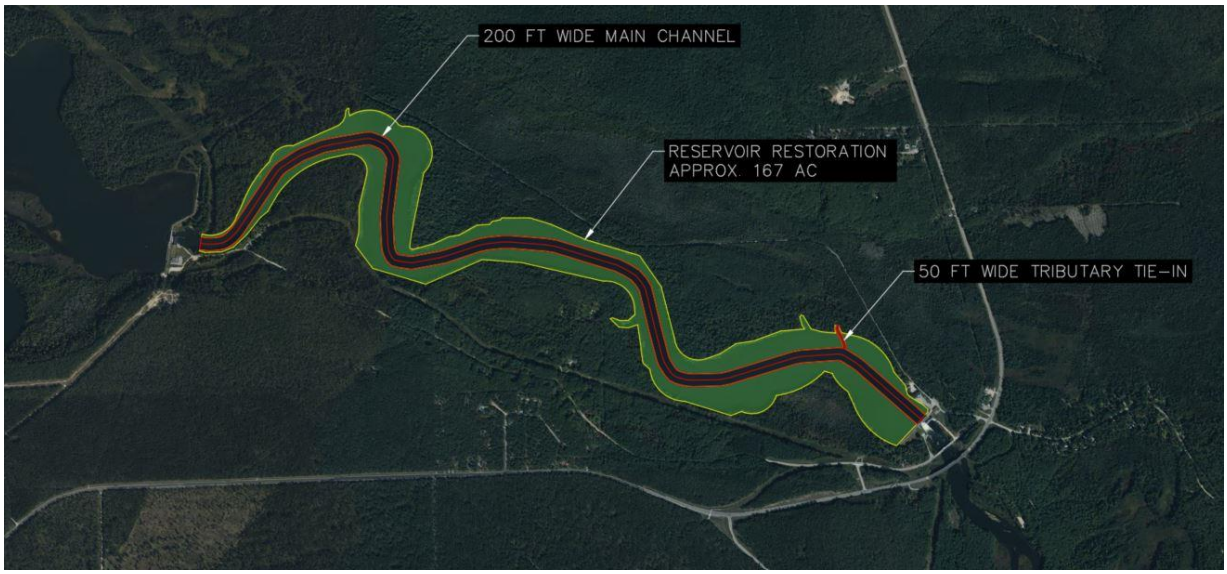


- Study of Water Left of Powerhouse in Groin Area
- Study of Wall Left of Powerhouse
- Unit Upgrades
- Backside Upstream Side of Powerhouse Leaking (might be addressed with Dead Bay Project)
- Units 1 and 2 Concrete Repairs

Generation

The Five Channels development consists of 2 units with a calculated maximum generation capacity of 52,560 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 25,032 MWH, contributing 6% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 32,728 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - It is unlikely that the Five Channels Dam will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
  - It is anticipated that less dredging will be required within this reservoir due to it being located directly downstream of the Loud Dam where a large portion of upstream sediments have already settled out. The existing 212-acre reservoir more closely mimics a wide river than a true reservoir. Limited bathymetry is available but based on aerials it looks to preserve the natural channel within the reservoir.
  - Less intense planning and analysis required to determine how to manage existing recreational features since reservoir shoreline should not significantly recede. There are also very few recreational features along this reservoir shoreline.

- Cons/Risks
    - Features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - May also still cause sediment transport issues. The Five Channels Dam should be removed after removal of all upstream dams and before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Additional costs will be required to remove office buildings and warehouses adjacent to the dam. Contaminant surveys should be conducted for these buildings.
    - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to agriculture, uninhabited buildings, structures, or township or county roads, where environmental degradation would be minimal, and where danger to individuals is slight or nonexistent.

Decommissioning (Full)

- Pros
    - Eliminates legal liability and maintenance of existing facilities.
    - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
    - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
    - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
        - Habitat can be restored along the entire footprint of the dam.
    - Eliminates sediment transport issues
    - It is unlikely that the Five Channels Dam impoundment will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
    - It is anticipated that less dredging will be required within this reservoir due to it being located directly downstream of the Loud Dam where a large portion of upstream sediments have already settled out. The existing 212-acre reservoir more closely mimics a wide river than a true reservoir. Limited bathymetry is available but based on aerials it looks to preserve the natural channel within the reservoir.
    - Less intense planning and analysis required to determine how to manage existing recreational features since reservoir shoreline should not significantly recede. There are also very few recreational features along this reservoir shoreline.
- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Five Channels Dam should be removed after all upstream dams and before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Additional costs will be required to remove office buildings and warehouses adjacent to the dam. Contaminant surveys should be conducted for these buildings.

License Surrendering (Non-Power Operation)

- Pros
  - Lower initial cost burden
  - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
  - Fish passage improved, but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Office buildings and warehouses adjacent to dam can remain in place.
- Cons/Risks
  - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
    - Future repairs to dam structure.
  - Fish passage installation required.
  - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

APPENDIX B.10

Cooke Dam
FERC No. P-2450

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Two, 50-feet-high earth embankment dam sections, each with a concrete core wall.
- A 25-foot-high concrete spillway with three, 15-foot-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with an 11.5-foot-high concrete weir located approximately 50 feet downstream.
- A reservoir with a normal surface area of 1,627 acres at elevation 678.5 feet (USGS datum) and a gross storage of 26,749 acre-feet.
- A concrete and masonry powerhouse containing three generating units with a total installed capacity of 7,500 kW.
- An approximately 120-foot-long concrete tailrace with retaining walls.
- Associated appurtenant structures.
- Recreation Facilities consist of Iargo Springs, Canoer's Memorial, and Lumberman's Monument.
- Peaking Operations

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- Cooke Dam listed on National Register of Historic Places (NRHP)
- Considerable Public Recreation use on Au Sable River
- Majority public lands (USFS) and limited private property adjacent to shoreline

Future License Conditions

- Operations monitoring/automation
- Recreation enhancements
- RTE Species Wildlife Management Plans
- Sediment Management
- Consult with USFS
- Land Management plan for buffer lands
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- Historic Properties Management Plan
- Retirement study
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Fish passage requirements
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled “Cooke Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo,” The interior of the powerhouse structure was given a 'Green' rating, indicating that major repair will not be needed for about 10 to 20 years. However, the exterior powerhouse was given a rating of ‘Blue,’ corresponding to 5 to 10 years until major repairs are needed. The ‘blue’ rating is due to deterioration of the left exterior concrete powerhouse and Unit #3 penstock exterior wall. It is recommended that destructive testing be performed to evaluate the concrete and the potential extent of rehabilitation.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder between May and July 2018 and consisted of an assessment of the concrete features/structures (Downstream Left Embankment Retaining Wall, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Log Chute, Powerhouse Apron, Spillway Abutment, Downstream Spillway Apron, Spillway Structural Walkway Deck, Training Wall, Tumble Bay and Spillway, Upstream Left Wing Wall, Upstream Right Wing Wall, Upstream Spillway Apron, Upstream Spillway Piers) and spillway structural walkway. The findings were summarized in a condition assessment report for Cooke Hydroelectric Dam (dated January 4, 2019).

The key findings from the Cooke condition assessment identified two site features (the right downstream embankment retaining wall and the log chute) that were rated as YELLOW (3 to 5 years before major repairs or replacement is necessary). Two site features (the left and right upstream wing walls) were rated as BLUE (5 to 10 years before major repairs or replacement is necessary). Other structures that were inspected during this condition assessment and are included in this report were given a GREEN rating (10 to 20 years before major repairs or replacement is necessary).

DIVE INSPECTION

- Upstream Powerhouse & Spillway, July 17, 2018:
    - Two horizontal cracks and one vertical open construction joint at the South retaining wall. Three concrete spalls were observed in the open construction joint.
    - The South wing wall has one vertical crack and three diagonal cracks.
    - The steel trash rack bars were deteriorated up to 10%. Trash racks were approximately 20% blocked with debris.
    - One diagonal crack was observed in the divider pier between the powerhouse and the spillway.
    - One concrete spall and one open vertical construction joint were observed in the north retaining wall. The North wing wall has one vertical crack and one concrete spall.
    - One horizontal crack was observed at the north divider pier at Bay #1.
- Downstream Powerhouse & Spillway, July 18, 2018:
    - Lifting chains and connectors in the upstream spillway were deteriorated by up to 10%.
    - One horizontal crack at the north retaining wall along the upstream spillway. One concrete spall at the construction joint between the wing wall and the North retaining wall.
    - Trash rack bars are deteriorated up to 10% throughout. Trash racks in Bay #3 are completely blocked with Zebra mussels. Bay 3 is a dead bay with not generating unit installed.
    - One concrete spall at the pier between Bay #s 2 and 3.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

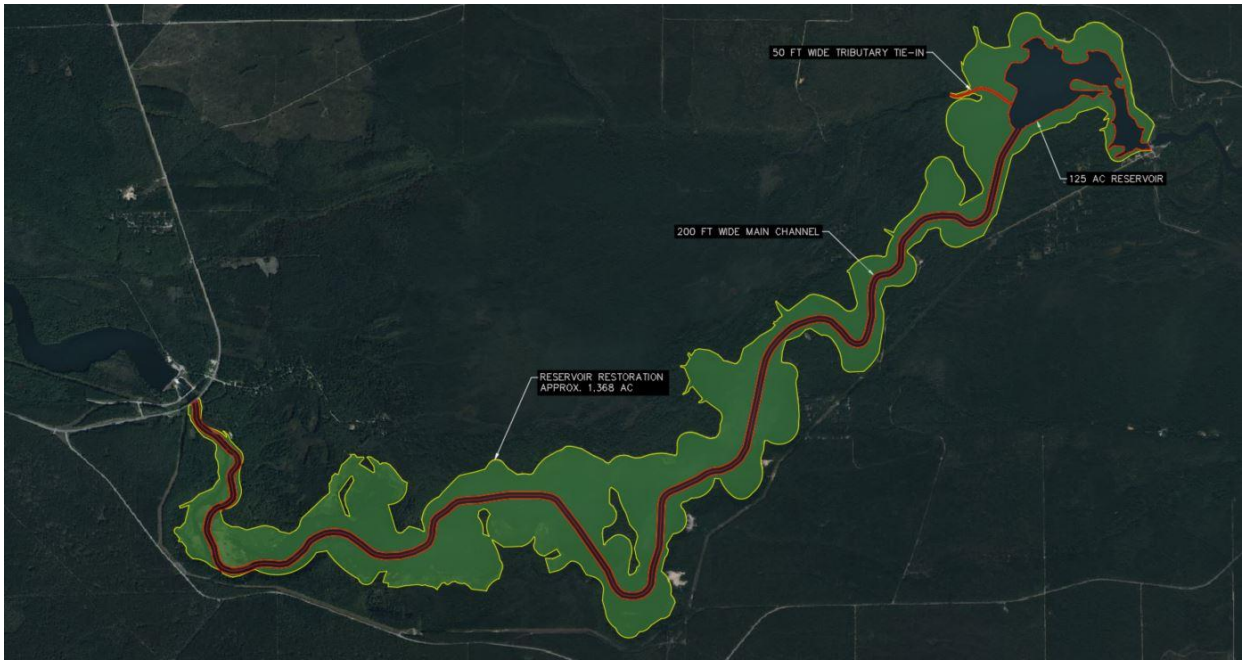
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement.

Current Remediation Projects in LTFP

- Headgate Replacement – Capital
- Plant Lighting Upgrade – Capital
- Midslope Retaining Wall Replacement – Capital
- Remote Spillgate Control Installation – Capital
- Right Embankment Retaining Wall Replacement – Capital
- Left Embankment Core Wall Addition – Capital
- Right Embankment Core Wall Slab Extension – Capital
- Spillway Hoist Replacement – Capital
- Electrical Safety Upgrade – Capital
- Step Up Transformer (GSU) Replacement – Capital
- Station Battery Replacement – Capital
- Powerhouse Window Replacement – Capital
- Apron Joint/Crack Sealant -O&M
- Log Chute Concrete Repair – O&M
- Powerhouse Divider Wall Pier Repair – O&M
- Unit 1 Intake Deck Concrete Repair – O&M
- Right and Left Upstream Wingwall Repair – O&M

Remediation Projects not in LTFP

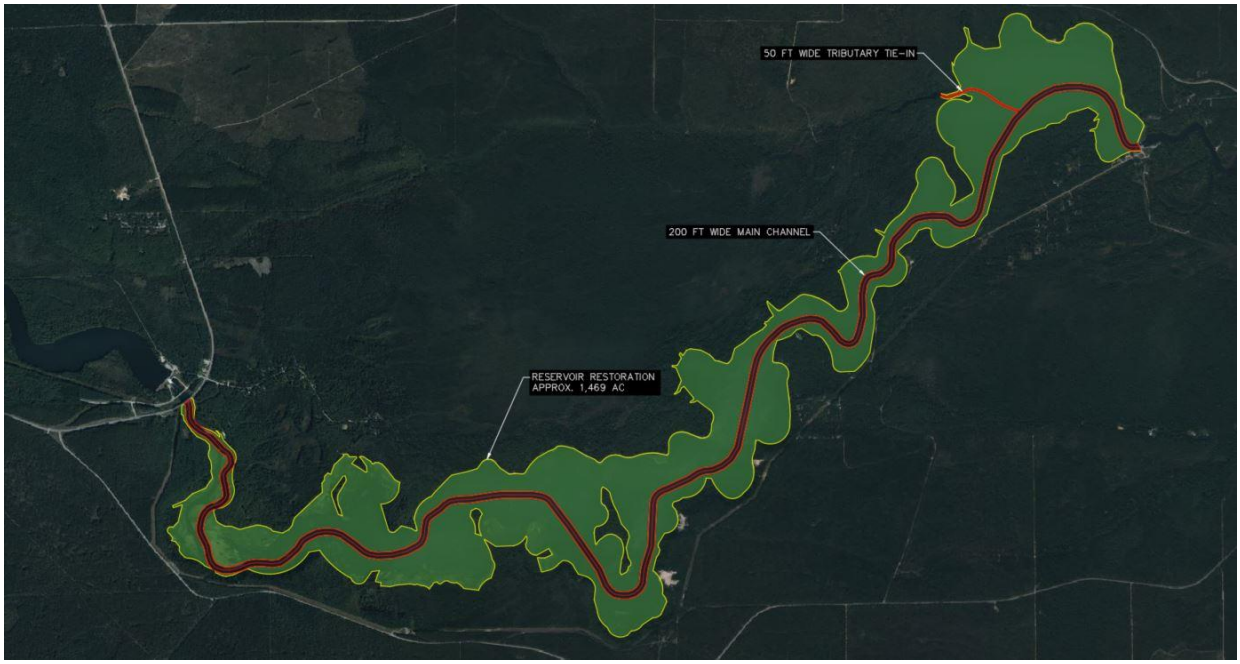


- Concrete Hallway Chambers Remediation
- Powerhouse Basement Concrete Repairs
- Units 1, 2, and 3 Concrete Repairs

Generation

The Cooke development consists of 3 units with a calculated maximum generation capacity of 78,840 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 27,803 MWH, contributing 6% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 39,568 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - It is unlikely that the Cooke Dam impoundment will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
  - Installing a new dam/weir structure will preserve the secondary barrier for invasive species attempting to travel upstream from Lake Huron.

- Cons/Risks
    - Auxiliary spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - The 46 kV substation will need to be relocated outside of the floodplain.
    - May also still cause sediment transport issues. The Cooke Dam should be removed after removal of the Mio, Alcona, Loud and Five Channels dams and before the Foote Dam so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
        - The Cooke Dam also received a State Historic Marker in 2005 and is on the National Register of Historic Places, which may create additional resistance to the dam removal.
    - Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir extents.
    - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to agriculture, uninhabited buildings, structures, or township or county roads, where environmental degradation would be minimal, and where danger to individuals is slight or nonexistent. This opinion is based on the following considerations:
        - Two inhabited residential properties located along left riverbank 1,600 FT downstream of dam (located at high enough elevation to not be at a significant risk of damage)
        - Au Sable River Camping sites located along left and right banks starting at approximately 4,000 FT downstream of dam

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
    - Habitat can be restored along the entire footprint of the dam.
  - Eliminates sediment transport issues
  - It is unlikely that the Cooke Dam impoundment will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.

- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Cooke Dam should be removed after all upstream dams and before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - The 46 kV substation will need to be relocated outside of the floodplain.
    - The dam serves as a secondary barrier to invasive species attempting to travel upstream from Lake Huron behind Foote Dam. Additional costs may be required to install sea lamprey control barriers (such as the FishPass system).
    - Public disapproval of this option due to its socioeconomic and recreational impact.
        - The Cooke Dam also received a State Historic Marker in 2005 and is on the National Register of Historic Places, which may create additional resistance to the dam removal.
    - Significant planning and analysis required to determine how to manage existing recreational features.

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
    - The 46 kV substation could also remain in place under this option.
    - Keeping the dam in place will preserve the secondary barrier for invasive species attempting to travel upstream from Lake Huron.
- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
        - Future repairs to dam structure.
    - Fish passage installation required.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

APPENDIX B.11
Foote Dam
FERC No. P-2436

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Two, 55-feet-high earth embankment dam sections, each with a concrete core wall.
- A 30-feet-high concrete spillway with three, 14.5-feet-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with a 12-feet-high concrete weir located approximately 65 feet downstream.
- A reservoir with a normal surface area of 1,702 acres at elevation 639.2 feet (U.S. Geological Survey [USGS] datum) and a gross storage of 32,380 acre-feet.
- A concrete and masonry powerhouse containing three generating units with a total installed capacity of 7,229 kilowatts (kW).
- A 25-feet-long concrete apron in the tailrace with concrete and sheet pile (right downstream side only) retaining walls extending 165 and 290 feet downstream, respectively.
- Associated appurtenant structures.
- Run-of-River operations

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- Water Quality out of compliance for temp and potentially dissolved oxygen (DO)
- Considerable Public Recreation use on Au Sable River. Foote Reservoir known for fishing and boating as most downstream reservoir and proximity to Lake Huron
- Majority public lands (USFS) and limited private property adjacent to shoreline
- Reservoir closest to Oscoda and Au Sable (population centers) on Lake Huron and potential for more public input different from reservoirs and reaches higher in the watershed (regional differences in interest areas)

Future License Conditions

- Operations monitoring/automation
- Water Quality mitigation/monitoring
- Recreation enhancements
- RTE Species Wildlife Management Plans
- Sediment Management
- Consult with USFS
- Land Management plan for buffer lands
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- Historic Properties Management Plan
- Retirement study
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Fish passage requirements or mitigation
- Temperature and potential DO exceedances
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Foote Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo," The exterior powerhouse structure was given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. However, the interior powerhouse was given a rating of 'Yellow,' corresponding to 3 to 5 years until major repairs are needed. The 'Yellow' rating is due to observed cracks and enlarged joints which indicate movement of the structure, particularly at the downstream left corner of the powerhouse. It is recommended that additional monitoring of the observed movement be performed moving forward, including periodic photographic documentation and additional survey points. It is also recommended that a thorough inspection of the interior crane be performed by a firm that certifies cranes.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder between June and July 2018 and consisted of the concrete features/structures (Downstream Left Embankment Retaining Wall, Downstream Powerhouse Apron, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Emergency Spillway Concrete Sloping Wall, Log Chute, Spillway Abutment, Downstream Spillway Apron, Spillway Structural Walkway Deck, Training Wall, Tumble Bay and Spillway, Upstream Left Wing Wall, Upstream Powerhouse Piers, Upstream Right Wing Wall, Upstream Spillway Apron, Upstream Spillway Piers) and spillway structural walkway. The findings were summarized in a condition assessment report for Foote Hydroelectric Dam (dated January 4, 2019).

The key findings from the Foote condition assessment identified two site features (the log chute and training wall) that are rated as BLUE (5 to 10 years before major repairs or replacement is necessary). In addition, the vertical joint at the transition between the sloped and horizontal portions of the downstream right embankment retaining wall should be repaired of damaged concrete and the joint cleaned and re-sealed. Less than 50% of the emergency spillway concrete sloping was visible and it is recommended the wall be cleared of vegetation overgrowth so that the remainder of the wall can be properly inspected. Golder recommended that the spillway structural walkway

deck be refinished in areas with protective coating loss to ensure corrosion does not reduce the design life of the structure, as well as cleaning and re-sealing of the joints between slabs. The joint between the wing walls and abutments on both the left and right wing walls should continue to be monitored during routine dive inspections. The grout seal for an old cofferdam used for construction on the upstream side of the spillway has exhibited spalling and should continue to be monitored to ensure the irregular surface does not cause advanced spalling of the existing apron concrete. Cleaning and resealing of the joints between the upstream spillway piers and structural walkway deck that were observed to have loose and separated sealant is also recommended. Other structures that were inspected during this condition assessment and included in this report were given a Green rating (10 to 20 years before major repairs or replacement is necessary).

DIVE INSPECTIONS

- Powerhouse, July 30, 2018:
    - One concrete spall and an open construction joint at the upstream south retaining wall.
    - The trash racks are deteriorated up to 10%.

  - The upstream concrete divider pier between bays 2 and 3 spalled at the water surface.
  - One concrete spall and an open vertical construction joint at the downstream south retaining wall.
  - One vertical concrete crack between the log chute and draft tube bay 1.
  - Construction joints in the downstream apron slab at several locations, and 7 areas of concrete spalling.
- Spillway, July 31, 2018:
  - One open construction joint between the north upstream retaining wall and the north wing wall.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

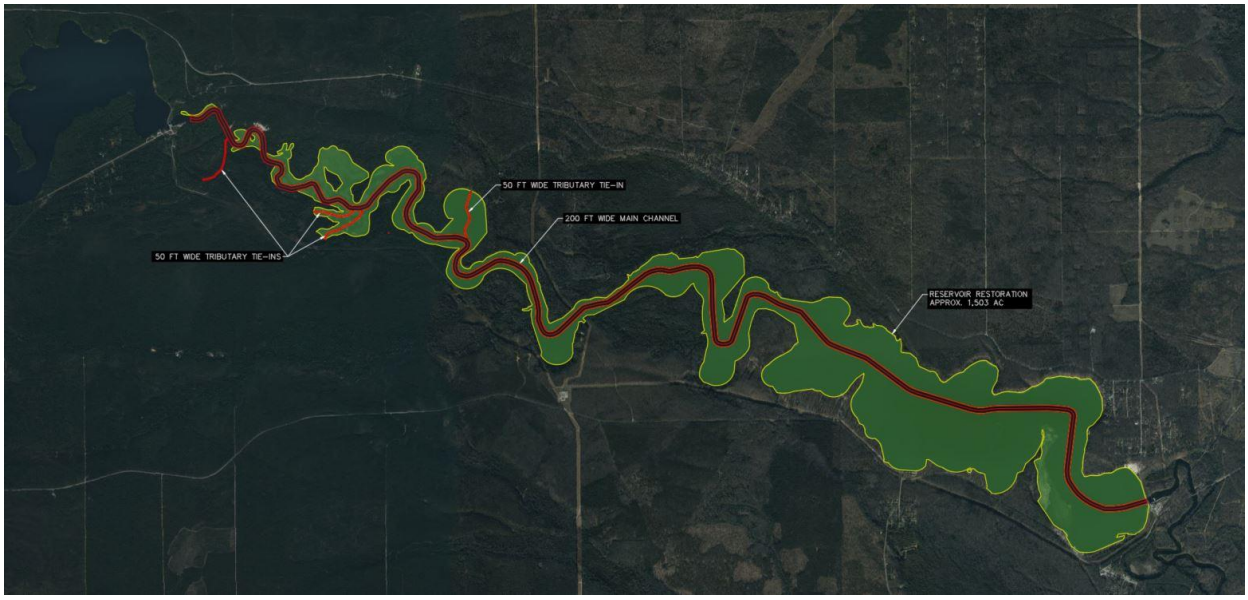
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require as significant amount of capital to implement.

Current Remediation Projects in LTFP

- ADA Ramp Replacement – Capital
- Units 1, 2, and 3 Governor Replacement – Capital
- Fish Net Frame Removal – Capital
- Spillway Hoist Replacement – Capital
- Trash Rack Ergonomics Project – Capital
- Electrical Safety Project – Capital
- Station Battery Replacement – Capital
- Unit 2 Wicket Gate Replacement – Capital
- Right Steel Sheet Pile Cut Off Wall PMF Overtopping Replacement – Capital
- Auxiliary Spillway Pilot Channel and Embankment Crest Grading – O&M
- Downstream Concrete Repairs – O&M

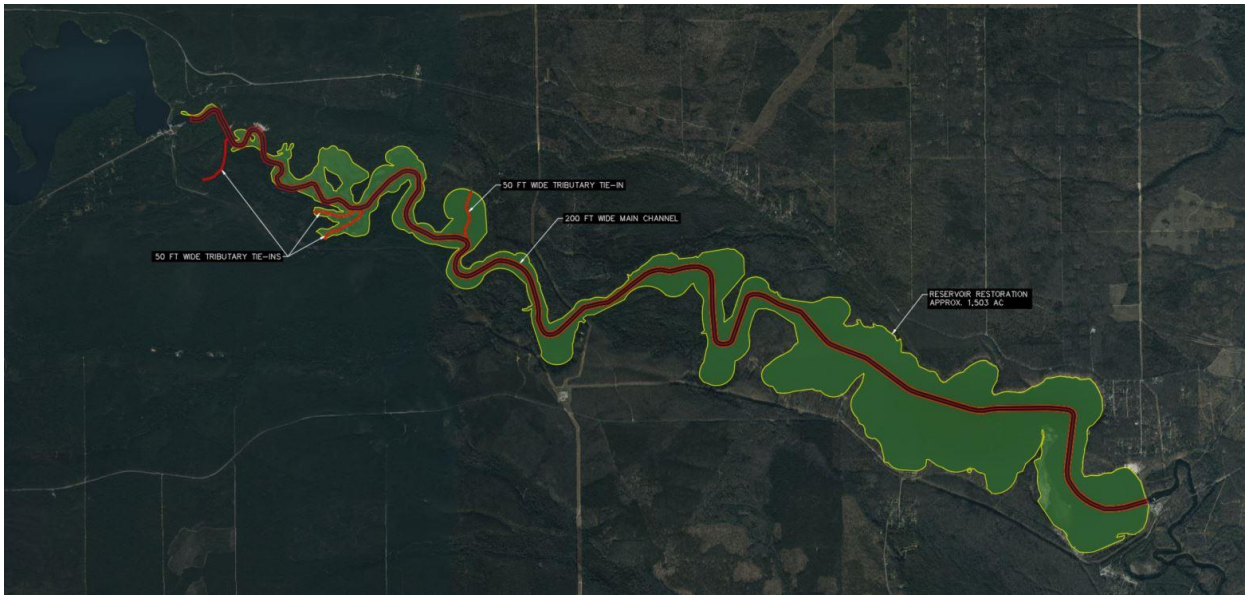
Remediation Projects not in LTFP



- Emergency Spillway
- Powerhouse Basement Leaks
- Units 1 and 3 Headgate Realignment
- Units 1, 2, and 3 Concrete Repairs
- Left Downstream Powerhouse Wall Remediation/Repair

Generation

The Foote development consists of 3 units with a calculated maximum generation capacity of 78,840 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 30,711 MWH, contributing 7% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 61,642 MWH.



Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)

Decommissioning (Partial)

- Pros
    - Reduces legal liability and maintenance of existing facilities.
    - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
    - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
    - It is unlikely that the Foote Dam will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
    - Installing a new dam/weir structure will preserve the primary barrier for invasive species attempting to travel upstream from Lake Huron.
- Cons/Risks
    - Emergency spillway and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Water quality (temperature and potential DO) may still be out of compliance for cold water fisheries under License Article 405.
    - May also still cause sediment transport issues. The Foote Dam should be removed after removal of all upstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Fish passage system should be designed with consideration to allow desirable species (Lake Sturgeon) and prevent non-desirable species (Sea Lamprey) from upstream migration.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
        - Archeological sites are also reported to be contained within the project area, which may create additional resistance to the dam removal.
    - Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir extents.
        - There are several homes located along the reservoir edge that are part of the Bissonette subdivision and Seven Mile Hill HOA, many of which have their own private boat docks.
    - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to agriculture, uninhabited buildings, structures, or township or county roads, where environmental degradation would be minimal, and where danger to individuals is slight or nonexistent.

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
    - Habitat can be restored along the entire footprint of the dam.
  - Eliminates issues of water quality (temperature and potential DO).
  - Eliminates sediment transport issues
  - It is unlikely that the Foote Dam impoundment will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Foote Dam should be removed after all upstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
  - The dam serves as a primary barrier to invasive species attempting to travel upstream from Lake Huron. Additional costs may be required to install sea lamprey control barriers (such as the FishPass system by the Great Lakes Fishery Commission).

- Public disapproval of this option due to its socioeconomic and recreational impact.
    - Archeological sites are also reported to be contained within the project area, which may create additional resistance to the dam removal.
- Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir extents.
    - There are several homes located along the reservoir edge that are part of the Bissonette subdivision and Seven Mile Hill HOA, many of which have their own private boat docks.

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
    - Keeping the dam in place will preserve the primary barrier for invasive species attempting to travel upstream from Lake Huron.
- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
        - Future repairs to dam structure.
    - Fish passage installation required.
    - Water quality (temperature and potential DO) may still be out of compliance for cold water fisheries under License Article 405. Significant costs may be required bring the water temperature into compliance to support cold water fisheries.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender to test the market and negotiate with potential buyers.

APPENDIX B.12

Webber Dam
FERC No. P-2566

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- Two, 32-foot-high earth embankment dam sections, each with a concrete core wall and totaling 730 feet in length.
- A 33-foot-high concrete spillway with ten steel radial gates and a fixed-crest overflow section which discharge to a concrete apron extending approximately 105 feet downstream.
- A reservoir with a normal surface area of 660 acres at elevation 684.4 feet (U.S. Geological Survey [USGS] datum) and a gross storage of 6,000 acre-feet.
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 3,250 kilowatts (kW).
- A 186-foot-long concrete-lined tailrace with retaining walls and downstream weir.
- Associated appurtenant structures.
- Fish ladder owned and operated by Michigan DNR (not in FERC license)
- Canoe portage trail around west side of dam.
- One to two dozen private residences/docks on reservoir

Relicensing Issues

- Major license (referenced in License Order, subject to form L-3)
- Considerable fisheries resource issues
- Considerable Public Recreation Facilities
- Limited private property adjacent to shoreline

Future License Conditions

- Operations monitoring/automation
- Recreation monitoring or enhancements
- RTE and Wildlife Species Management Plans
- Invasive vegetation monitoring plan
- Fish stocking/funding
- Recreation enhancements (portage improvements, paddler trail opportunities)
- Land/Shoreline Management
- Historic Properties Management Plan
- Operational restrictions (run-of-river monitoring, seasonal shutdowns)
- Seasonal shutdown (April) for downstream salmonid smolt migration

Risks to Operating under another 50-year License

- Invasive fish passage if downstream barriers are removed
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled “Webber Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo,” The exterior and interior powerhouse structure was given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. While no immediate major repairs are required, additional maintenance and monitoring is recommended to prevent further need for repairs.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder on September 28 and 29, 2018 and consisted of the above-water concrete features/structures (Downstream Left Embankment Retaining Wall Segments 1 and 2, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Downstream Spillway Apron (Exposed), Downstream Triangle, Fish Ladder, Fixed Crest Spillway, Left Wing Wall/Abutment, Right Wing Wall/Abutment, Spillway Abutment, Spillway, Piers, and Weir - Left

Segment and Right Segment, Training Wall Segments 1 and 2, Upstream Spillway Piers, Upstream Triangle).

The key findings from the Webber condition assessment identified one site feature (segment 2 of the training wall) that was rated as ORANGE (1 to 3 years before major repairs or replacement is necessary). One site feature (segment 1 of the training wall) was rated as BLUE (5 to 10 years before major repairs or replacement is necessary). Continued monitoring of segment 2 of the left embankment retaining wall is recommended to determine if the movement noted during the inspection is on-going. In addition, periodic maintenance including cleaning and sealing of the joints in the downstream left embankment retaining wall, fixed crest spillway and between the spillway abutment and left embankment retaining wall is recommended. Other structures that were inspected during this condition assessment and are included in this report were given a Green rating (10 to 20 years before major repairs or replacement is necessary).

DIVE INSPECTIONS

- July 20-21 and September 28, 2022:
    - The underwater portions of the Webber Hydroelectric Dam were in overall good condition. All features/structures were given a green rating, indicating that that major repair will not be needed for about 10 to 20 years. Deficiencies were limited to spalling, concrete aggregate pop-outs, minor to moderate cracking, surface scaling/erosion, and concrete surface flaking.
    - Additional underwater monitoring is recommended every 5 years. Continued removal of debris from the upstream powerhouse trash racks and spillway is also recommended.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

CURRENT PART 12 RECOMMENDATIONS:

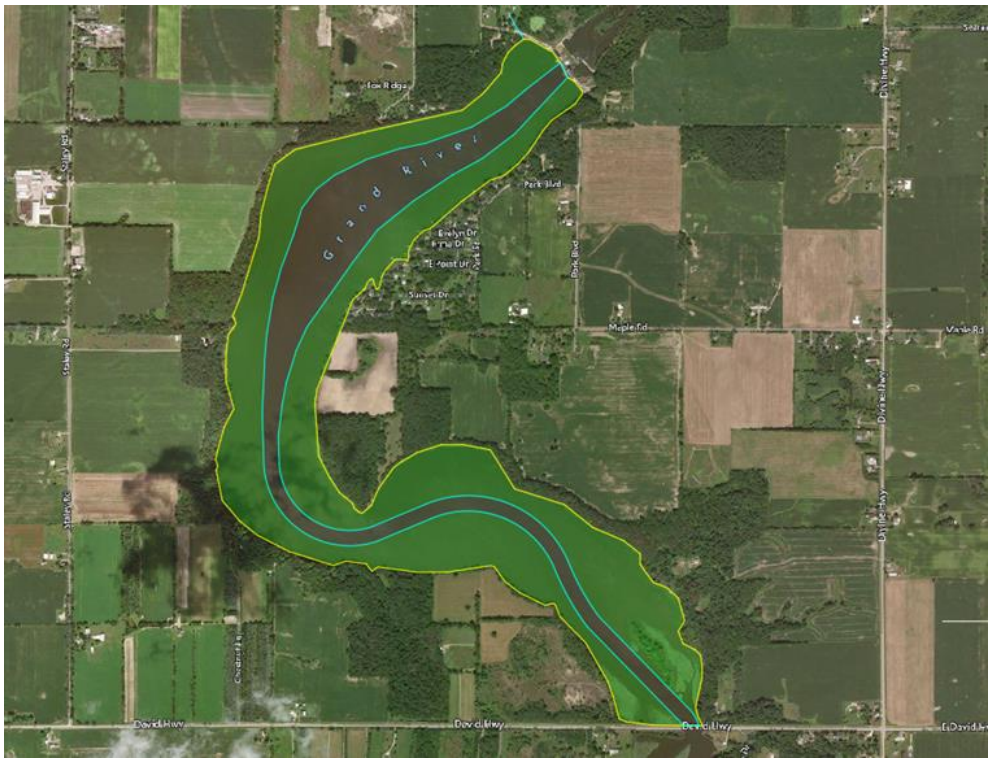
Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require as significant amount of capital to implement. The exception to this is the potential for repair of the tumble bay slab pending the study to determine the mechanism causing voids.

Current Remediation Projects in LTFP

- Unit 1 Overhaul and Generator Rewind – Capital
- Left Downstream Spillway Abutment Wall Replacement – Capital

- Unit 2 2400V Switchgear Replacement – Capital
- Unit 1 Concrete Repairs – O&M

Remediation Projects not in LTFP

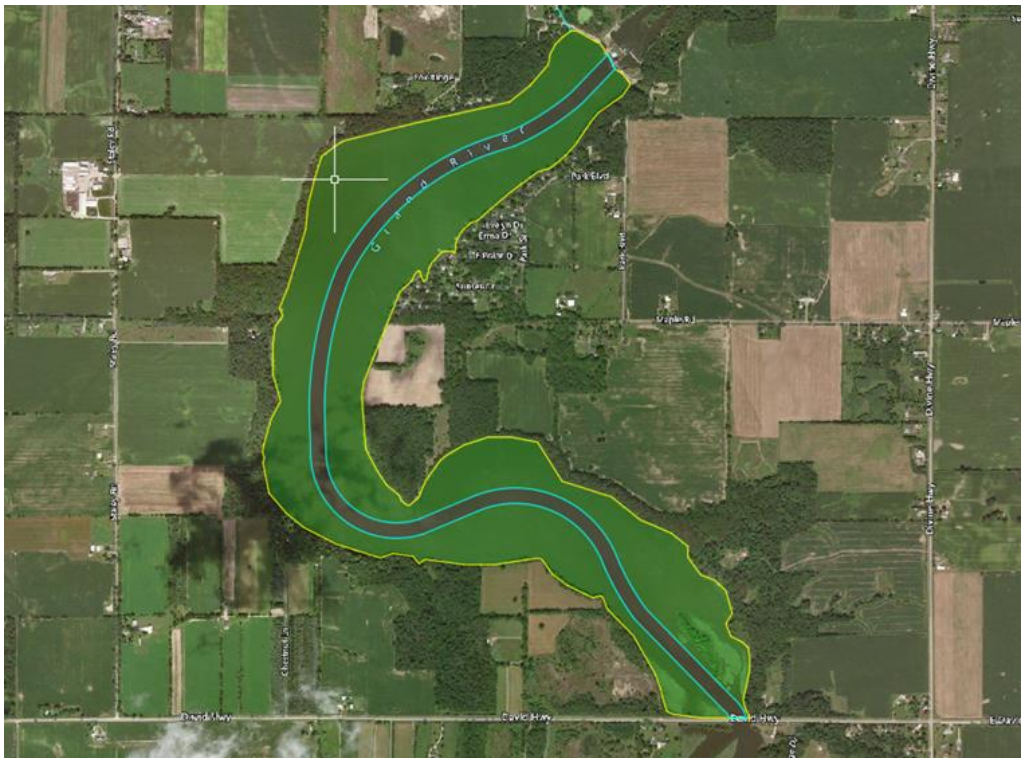


- Upstream Triangle Concrete Wall Remediation
- Right Embankment Toe Seepage Repair
- Core Wall Extension
- Unit 2 Bolt Replacement
- Draft Tube Concrete Repairs
- Downstream Powerhouse Pier Concrete Repairs
- Unit 2 Concrete Repairs

Generation

The Webber development consists of 2 units with a calculated maximum generation capacity of 37,668 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 11,271 MWH, contributing 3% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 18,900 MWH.

Surrendering (projected to 2041 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish ladder already installed.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
- Cons/Risks
  - This option will require significant coordination with regulatory agencies and external stakeholders due to changes in land use, majority of surrounding property is residential
  - New fish passage installation required.
  - May also still cause sediment transport issues.
  - Public disapproval of this option due to its socioeconomic and recreational impact (does not solve issue of poo portage for anglers and recreational boaters and paddlers).

- May serve as sea lamprey barrier with recent removal of Lyons Dam and potential removal of the partially failed Wager Dam downstream.
- Endangered unionid mussels at dam impoundment and tailwaters may be impacted by dam removal.
- Sediment release from removal may impact restoration conducted for Lyons Dam removal and potential Wager Dam removal downstream
- Impoundment may buffer water quality impacts associated with extensive upstream development, agriculture, septic issues, and point sources.
    - Potential for contaminated sediment removal and disposal will add significant cost burden.
- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists.

Decommissioning (Full)

- Pros
    - Eliminates legal liability and maintenance of existing facilities.
    - Fish ladder already installed.
    - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.

  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
  - Habitat can be restored along the entire footprint of the dam.
  - Eliminates sediment transport issues
  - Improved portage for anglers and recreational boaters and paddlers. A new boat launch downstream of Webber Dam is desired by the community now that the downstream Lyons Dam has been removed, but full removal of Webber may solve this issue.
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Public disapproval of this option due to its socioeconomic and recreational impact.
  - May serve as sea lamprey barrier with recent removal of Lyons Dam and potential removal of the partially failed Wager Dam downstream.
  - Endangered unionid mussels at dam impoundment and tailwaters may be impacted by dam removal.
  - Sediment release from removal may impact restoration conducted for Lyons Dam removal and potential Wager Dam removal downstream
  - Impoundment may buffer water quality impacts associated with extensive upstream development, agriculture, septic issues, and point sources.
    - Potential for contaminated sediment removal and disposal will add significant cost burden.

License Surrendering (Non-Power Operation)

- Pros
  - Lower initial cost burden
  - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
  - Contaminated sediments do not need to be removed and transported offsite.
  - Fish ladder already installed.
  - No disturbance to endangered unionid mussels found in dam impoundment and tailwaters.
  - Serves as sea lamprey barrier if partially failing Wager Dam is removed downstream.
- Cons/Risks
  - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
    - Future repairs to dam structure.
  - Transport of sediment and woody debris is also not improved through this option.

Divesting

Relicensing decision is further out than the Au Sable, Manistee, and Muskegon River projects. Putting this project on the market as part of a large portfolio is a near term action that can inform the next decisions. There is time before having to make a decision on relicensing or surrender.

APPENDIX B.13

Allegan (Calkins Bridge) Dam
FERC No. P-785

Submitted to:

Consumers Energy Company

1945 W. Parnall Road

Jackson, Michigan USA 49201

Submitted by:

WSP

809 Delta Avenue, Gladstone, Michigan USA 49837

+1 906-420-840

April 2023

Site Characteristics

- A 30-feet-high earth embankment dam section totaling 1,335 feet in length.
- A 132-feet-long concrete spillway with six steel radial gates which discharge to a concrete apron extending approximately 54 feet downstream.
- A reservoir with a normal surface area of 1,550 acres at elevation 615.0 feet (U.S. Geological Survey [USGS] datum) and a gross storage of 17,000 acre-feet.
- A concrete and masonry powerhouse containing three generating units with a total installed capacity of 2,550 kilowatts (kW).
- A 58-feet-long concrete-lined tailrace with retaining walls.
- Associated appurtenant structures.
- Low Hazard classification dam: Allegan Dam Road crosses across the top of or near the dam with integrated structural connections to the dam incorporated into design.

Relicensing Issues

- Major license (referenced in License Order, subject to form L-3)
- Indiana bat & Kerner Blue butterfly potential
- Potential archaeological resources
- Considerable Recreation use and access from MDNR Facilities
- Popular fishery downstream of dam
- Shoreline management and private property ownership
- Sediment pollution from upstream super fund site.

Future License Conditions

- Operations monitoring, automation and compliance
- Water Quality mitigation/monitoring
- Recreation enhancements
- RTE Species Management Plans
- Land/Shoreline Management
- Historic Properties Management Plan
- Operational run-of-river

Risks to Operating under another 50-year License

- Fish ladder was blocked with a removable plug in 1999 is a likely topic to investigate in next relicensing; however, Allegan may be best without it to limit invasive fish access and due to toxic sediments and fish consumption advisories in the Kalamazoo River
- Potential for temperature and dissolved oxygen (DO) exceedances
- Continued responsibility to meet regulatory requirements.
    - Operational monitoring for run-of-river, lake levels, and gage and instrumentation
    - Lake Sturgeon Spawning Habitat Enhancement Plan and a Reservoir Drawdown Management Plan
    - Downstream fish passage protection (existing racks 1.5 inch spacing)
    - Water quality monitoring downstream of the project and analyzing sediments and fish tissue in Lake Allegan for various contaminants, including total mercury and polychlorinated biphenyls (PCBs).
    - Plan to monitor and, where appropriate, control or eliminate invasive species and to implement measures to protect the Indiana bat, including restrictions on removing dead or dying trees near the shoreline.
    - Implement a Historic Properties Management Plan
    - Recreation: majority of use and access is provided by MDNR
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites.
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Allegan Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo," The exterior and interior powerhouse structure was given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. While no immediate major repairs are required, additional monitoring of cracks along interior columns and displacement of the exterior walkway is recommended.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder on September 28, 2018 and consisted of the above-water concrete features/structures (Downstream Left Embankment Retaining Wall, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Left Wing Wall/Abutment, Log Chute, Right Wing Wall/Abutment, Spillway Abutment, Spillway and Downstream Spillway Piers, Spillway Structural Walkway Deck, Upstream Powerhouse Piers, Upstream Spillway Piers). The findings were summarized in a condition assessment report for Allegan Hydroelectric Dam (dated May 14, 2019).

The structures that were inspected during this condition assessment and are included in this report were generally found to be in good condition and given a Green rating (10 to 20 years before major repairs or replacement is necessary).

DIVE INSPECTION

- July 7, 2021, and August 10, 2022 Underwater Condition Assessment
    - The underwater portions of the Calkins Bridge Hydroelectric Dam in overall good condition. All features/structures inspected were given a green rating, indicating that that major repair will not be needed for about 10 to 20 years. Deficiencies were limited to minor spalls, concrete aggregate pop-outs, minor cracking, surface scaling/erosion, and concrete surface flaking.
    - A vertical crack was observed in the upstream right wingwall, which was not observed in the 2016 underwater inspection. Additional monitoring of a vertical crack in the upstream right wingwall is recommended every 5 years. Continued removal of debris from the upstream powerhouse trash racks and spillway is also recommended.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

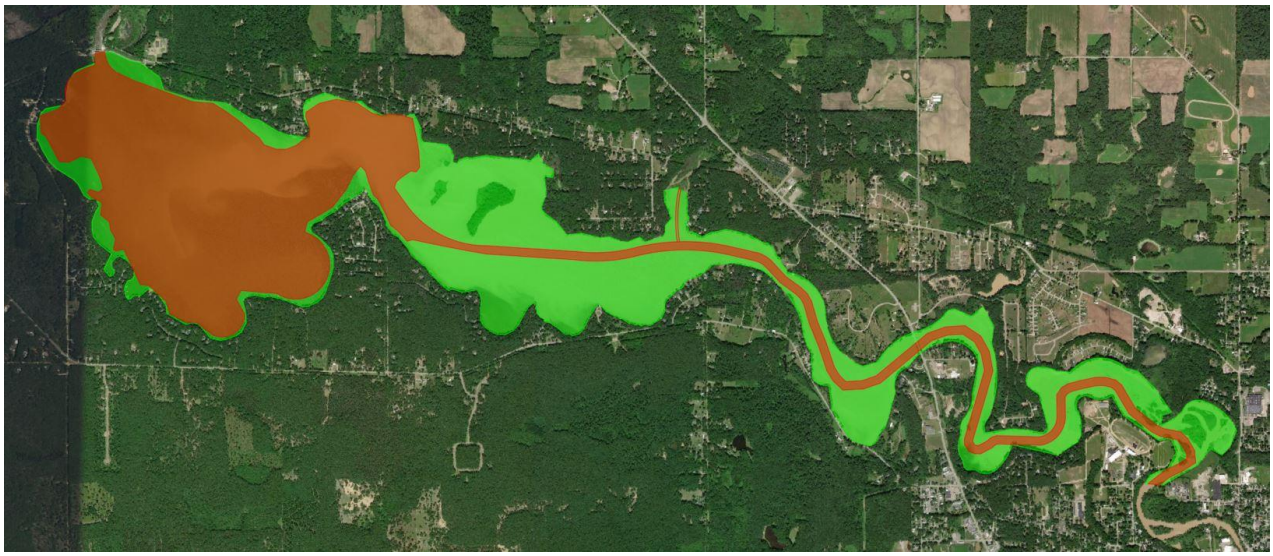
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require as significant amount of capital to implement.

Current Remediation Projects in LTFP

- Unit 1 Wicket Gate Replacement - Capital
- Powerhouse Roof Replacement – Capital
- Unit 3 Static Exciter Replacement – Capital
- 199 Breaker Replacement - Capital
- Units 1, 2, and 3 Governor Replacements – Capital
- Bridge Inspection (Structures and Improvements) – O&M
- Tailrace Access Safety Ergonomics – O&M

Remediation Projects not in LTFP

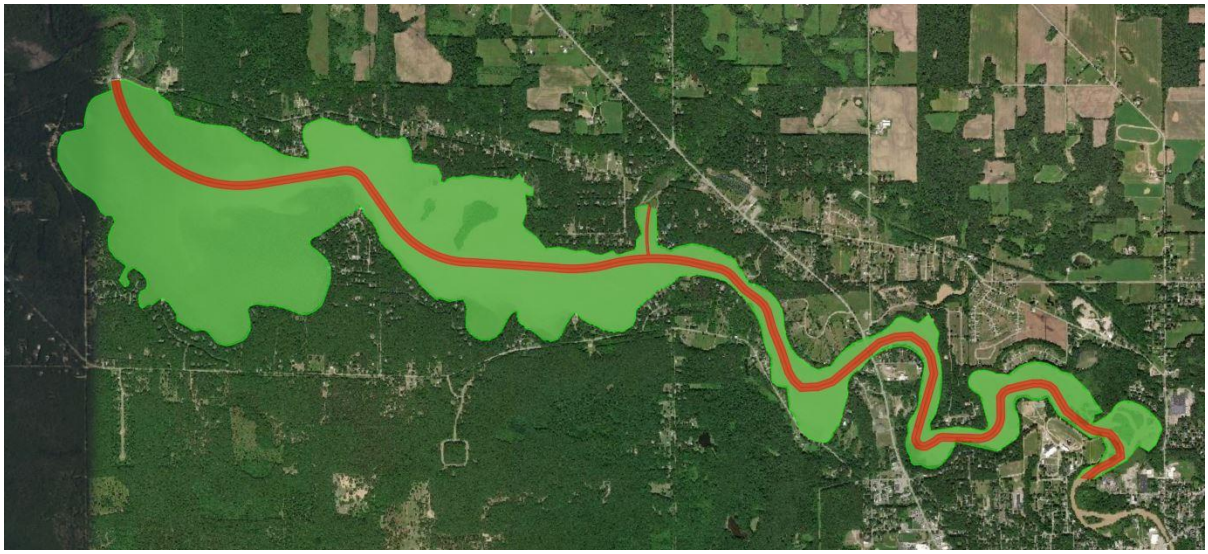


- Trash Rack Remediation
- Intake Concrete Repairs
- Powerhouse Concrete Repairs (From replacing wooden gates)
- Crane Remediation
- Units 1, 2, and 3 Concrete Repairs
- Back Deck Concrete Repairs
- Possible Bridge Replacement

Generation

The Allegan development consists of 3 units with a calculated maximum generation capacity of 22,338 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 13,628 MWH, contributing 3% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 15,432 MWH.

Surrendering (projected to 2040 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
- Cons/Risks
  - This option will require significant coordination with regulatory agencies and external stakeholders due to changes in land use, majority of surrounding property is residential
  - The dam and reservoir fall within the Allied Paper, Inc./Portage Creek/Kalamazoo River Superfund site. Sediment characterization required to determine distribution of potential contamination. Requires coordination with EPA to determine responsibility of cost burden.
    - EPA is currently working to remediate the Kalamazoo River, but this portion has not yet been reached. The dam is in Area 6 of Operable Unit 5 (OU5) in the cleanup plan. The EPA has completed cleanup on OU2, OU3, and OU4. Currently there are cleanup plans in place for OU1, OU7, and Areas 1, 2, and 3 of OU5. None are in place for Area 6 OU5 at this time.
  - Fish passage installation required. Fish passage system should be designed with consideration to allow desirable species (Lake Sturgeon) and prevent non-desirable species (Sea Lamprey) from upstream migration.

- Water quality (temperature and DO) may still be out of compliance for cold water fisheries under License Article 405.
- May also still cause sediment transport issues.
- Public disapproval of this option due to its socioeconomic and recreational impact.
- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to agriculture, uninhabited buildings, structures, or township or county roads, where environmental degradation would be minimal, and where danger to individuals is slight or nonexistent.

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
  - Habitat can be restored along the entire footprint of the dam.
  - Eliminates issues of water quality (temperature and DO).
  - Eliminates sediment transport issues

- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Potential for contaminated sediment removal and transport which will create a significant cost burden.
    - Barrier system should be installed to prevent upstream migration of invasive species (sea lamprey and round goby); refer to FishPass System example by Great Lakes Fishery Commission.

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage would not be addressed directly but requires installation of fish passage system; potential discontinuation of MDNR stocking.
    - Contaminated sediments do not need to be removed and transported offsite.
- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
        - Future repairs to dam structure.
    - Potential fish passage requirements.
    - Water quality (temperature and DO) may still be out of compliance for cold water fisheries under License Article 405. Upwelling system installation may add cost burden.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Relicensing decision is further out than the Au Sable, Manistee, and Muskegon River projects. Putting this project on the market as part of a large portfolio is a near term action that can inform the next decisions. There is time before having to make a decision on relicensing or surrender.

1 EXECUTIVE SUMMARY

Consumers Energy Company (Consumers) owns and operates 13 river hydro dam facilities located on the Muskegon, Manistee, Grand, Au Sable, and Kalamazoo Rivers. The average age of these assets is 106 years old and much of each site is original construction and equipment. Consumers would need to start relicensing 11 of the 13 projects with filings signaling their intentions no later than June 30, 2029, meaning a plan for the assets should be in place within the next few years to prepare for filing with Federal Energy Regulatory Commission (FERC). In addition, FERC has recently updated their Part 12 inspection requirements. The revised inspections put more emphasis on Potential Failure Mode Analysis, updated Probable Maximum Flood, and Semi-Quantitative Risk Analysis level 2 effort for each site. These enhanced regulations require subject matter experts and facilitators to complete portions of the work.

Consumers also conducts routine inspections and commissioned studies investigating the overall conditions of the facilities. Although not comprehensive, the assessments indicate the assets are in 'fair' condition but recognizes the current operations as run-of-river is inconsistent with the original peaking designs conceding efficiency and potential generation revenue. The combination of aging assets, increasing regulatory requirements which have resulted in potentially costly upgrades to some of the Project's spillways, system operations, and expected spend on necessary maintenance to keep the plants operating has raised the question of how to extract the best value out of these assets. To achieve this goal, Consumers hired WSP USA, Inc. (WSP) to prepare the 2023 Hydropower Roadmap (Roadmap) for the 13 hydroelectric dam sites which reviewed Consumers' provided facility reports and analyzed different outcome scenarios and characterized how to achieve them. This Roadmap analyzed six scenarios that included two for relicensing, three for surrendering the license, and one to investigate divesting. Within this pursuit, an additional goal of developing an economic model as a tool to rank the potential outcomes was later added.

This report details the surrendering considerations and pricing considered in the roadmap for 6 of the 13 hydropower facilities located within the Au Sable River Watershed, including the including Mio Dam in Oscoda County, Alcona Dam in Alcona County, and Loud, Five Channels, Cooke and Foote Dams in Iosco County.

Three surrender scenarios with specific assumptions were considered in preparing the cost estimates for each surrender option:

- Surrender– No-Power Generation: The no-power generation scenario evaluates surrender of the FERC license while not removing the dam structure. The powerhouse and spillway would be modified to maintain safe flows through the system while disconnecting generation equipment. The dam would remain in place and current reservoir levels would be maintained. Additional capital improvements would be required for long term compliance with dam safety regulations.
- Surrender and Decommission – Partial Removal: The partial removal scenario evaluates partial removal of the dam via reduction of the earthen dam structure with full removal of the powerhouse and generation facilities. This scenario evaluates the potential to leave some form of upstream reservoir system while developing a new weir control structure. This structure would be designed to fall under state regulations (Natural Resources and Environmental Protection Act (NREPA), Part 315, Dam Safety), not FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir and to prevent the proliferation of invasive species such as the sea lampreys.
- Surrender and Decommission - Full Removal: The full removal scenario evaluates the complete removal of the dam and reservoirs. The reservoirs would be drained, powerhouse/generation facilities and earthen dam structures fully removed, and the upstream channel and floodplain restored to pre-dam conditions.

For each facility and scenario, a class 5 cost estimate was prepared in Q4 2022 dollars, identifying and quantifying the value of the plant's assets and estimate of the cost of utility separation, decommissioning and demolition, abatement and

regulated material removal, environmental and restoration work of the AuSable River, as well as associated project indirect costs and recommended contingency. Schematics utilized for the evaluation of the Surrender and Decommission – Partial and Full Removal for how the reservoir may be reshaped in the decommissioning restoration are presented. Additional assumptions and limitations by site are presented herein.

2 INTRODUCTION

Consumers Energy Company (Consumers) owns and operates 13 river hydro dam facilities located on the Muskegon, Manistee, Grand, Au Sable, and Kalamazoo Rivers. The average age of these assets is 106 years old and much of each site is original construction and equipment. Consumers would need to start relicensing 11 of the 13 projects with filings signaling their intentions no later than June 30, 2029, meaning a plan for the assets should be in place within the next few years to prepare for filing with Federal Energy Regulatory Commission (FERC). In addition, FERC has recently updated their Part 12 inspection requirements. The revised inspections put more emphasis on Potential Failure Mode Analysis, updated Probable Maximum Flood, and Semi-Quantitative Risk Analysis level 2 effort for each site. These enhanced regulations require subject matter experts and facilitators to complete portions of the work.

Consumers also conducts routine inspections and commissioned studies investigating the overall conditions of the facilities. Although not comprehensive, the assessments indicate the assets are in 'fair' condition but recognizes the current operations as run-of-river is inconsistent with the original peaking designs conceding efficiency and potential generation revenue. The combination of aging assets, increasing regulatory requirements which have resulted in potentially costly upgrades to some of the Project's spillways, system operations, and expected spend on necessary maintenance to keep the plants operating has raised the question of how to extract the best value out of these assets.

To achieve this goal, Consumers hired WSP USA, Inc. (WSP) to prepare the 2023 Hydropower Roadmap (Roadmap) for the 13 hydroelectric dam sites which reviewed Consumers' provided facility reports and analyzed different outcome scenarios and characterized how to achieve them. This Roadmap analyzed six scenarios that included two for relicensing, three for surrendering the license, and one to investigate divesting. Within this pursuit, an additional goal of developing an economic model as a tool to rank the potential outcomes was later added. This report details costs and considerations prepared for 3 of the 13 hydropower facilities located along the Au Sable River system, including Mio in Oscoda County, Alcona Dam in Alcona County, Loud Dam, Five Channels Dam, Cooke Dam, and Foote Dam in Iosco County.

The Au Sable River system rises in the Northern Lower Peninsula of Michigan, the river flows in a generally southeasterly direction to its mouth at Lake Huron. It incorporates 5 counties including Otsego, Crawford, Oscoda, Alcona, and Iosco. The Au Sable River watershed drains more than 1,900 square miles of land area and runs approximately 130 miles.

The three surrendering scenarios include:

- Surrender – No-Power Generation
- Surrender and Decommission – Partial Removal
- Surrender and Decommission – Full Removal.

The objective of the conceptual decommissioning cost estimate is to identify the value of the plant's assets and estimate of the cost of utility separation, decommissioning and demolition, abatement and regulated material removal, environmental work, and restoration of the Au Sable River, as well as associated project indirect costs and recommended contingencies.

2.1 MIO DAM

The Mio dam (FERC Project Number 2448), located in the Au Sable River in Mio Township, Oscoda County, Michigan consists of two, 40-foot-high earth embankment dam sections, each with a concrete core wall. A 17-foot-high concrete spillway with one, 12.7-foot-high steel radial gate and a concrete-lined discharge channel extending approximately 220 feet downstream with a 6.5-foot-high concrete weir located approximately 45 feet downstream. A 530-foot-long auxiliary spillway located at the end of the south embankment dam. A 185-foot-long concrete tailrace with retaining walls. The reservoir, with a normal surface area of 661 acres at elevation 962.6 feet (U.S. Geological Survey [USGS] datum), has a gross storage of 6,061 acre-feet.

Additionally, the dam includes a concrete and masonry powerhouse containing two generating units with a total installed capacity of 3,885 kW. The powerhouse also contains two spill tubes used primarily as the service spillway. Both spill tubes are operational at this time.

2.2 ALCONA DAM

The Alcona dam (FERC Project Number 2447), located in the Au Sable River in Curtis Township, Alcona County, Michigan consists of two, 60-feet-high earth embankment dam sections, each with a concrete core wall, and a 250-feet-long emergency spillway located at the end of the east embankment.

Additionally, the dam includes a reservoir with a normal surface area of 1,006 acres at elevation 829.0 feet (USGS datum) with a gross storage of 12,547 acre-feet, a concrete and masonry powerhouse containing two generating units with a total installed capacity of 7,905 kW, and a 135-foot-long concrete tailrace with retaining walls. The powerhouse also contains six spill tubes used primarily as the service spillway.

2.3 LOUD DAM

The Loud dam (FERC Project Number 2449), located in the Au Sable River in Iosco County, Michigan consists of two, 42-foot-high earth embankment dam sections, each with a concrete core wall, a 20-foot-high concrete service spillway with three, 15.5-foot-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with a 6.5-feet-high concrete weir located approximately 45 feet downstream, and a 100-feet-long emergency spillway.

The dam maintains a reservoir with a normal surface area of 743 acres at elevation 742.6 feet (USGS datum) with a gross storage of 6,987 acre-feet, as well as concrete-and-masonry powerhouse containing two generating units with a total installed capacity of 4,000 kW, and a 35-foot-long concrete apron in the tailrace with concrete retaining walls extending approximately 125 feet downstream.

2.4 FIVE CHANNELS DAM

The Five Channels dam (FERC Project Number 2453), located in the Au Sable River in Iosco County, Michigan consists of two, 45-feet-high earth embankment dam sections, each with a concrete core wall and a 25-foot-high concrete service spillway with three, 14.5-foot-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with an 8-foot-high concrete weir located approximately 60 feet downstream. The reservoir, with a normal surface area of 212 acres at elevation 715.0 feet (U.S. Geological Survey [USGS] datum), has a gross storage of 3,419 acre-feet.

Additionally, the dam includes a concrete and masonry powerhouse containing two generating units with a total installed capacity of 5,966 kW with a 35-foot-long concrete apron in the tailrace with concrete retaining walls extending approximately 120 feet downstream

2.5 COOKE DAM

The Cooke dam (FERC Project Number 2450), located in the Au Sable River in Oscoda Township, Iosco County, Michigan consists of two, 50-feet-high earth embankment dam sections, each with a concrete core wall, a 25-foot-high concrete service spillway with three, 15-foot-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with an 11.5-foot-high concrete weir located approximately 50 feet downstream.

Additionally, the dam includes a reservoir with a normal surface area of 1,627 acres at elevation 678.5 feet (USGS datum) with a gross storage of 26,749 acre-feet, a concrete and concrete-and-masonry powerhouse containing three generating units with a total installed capacity of 7,500 kW with an approximately 120-foot-long concrete tailrace with retaining walls.

2.6 FOOTE DAM

The Foote dam (FERC Project Number 2436), located in the Oscoda Township, Iosco County, Michigan consists of two, 55-

feet-high earth embankment dam sections, each with a concrete core wall, and a 30-feet-high concrete service spillway with three, 14.5-feet-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with a 12-feet-high concrete weir located approximately 65 feet downstream.

Additionally, the dam includes a reservoir with a normal surface area of 1,702 acres at elevation 639.2 feet (USGS datum) with a gross storage of 32,380 acre-feet, a concrete and concrete-and-masonry powerhouse containing three generating units with a total installed capacity of 7,229 kilowatts (kW) with a 25-feet-long concrete apron in the tailrace with concrete and sheet pile (right downstream side only) retaining walls extending 165 and 290 feet downstream, respectively.

3 STUDY APPROACH

3.1 ASSUMPTIONS

WSP analyzed the costs for three scenarios involving the surrender of the hydropower facilities before the current license expires. These scenarios include 1) Surrender – No-Power Generation: 2) Surrender and Decommission – Partial Removal; and 3) Surrender and Decommission – Full removal. Detailed description of these alternatives are as follows:

Surrender – No Power Generation Operation

The no-power generation scenario evaluates surrender of the FERC license while not removing the dam structure. The powerhouse and spillway would be modified to maintain safe flows through the system while disconnecting generation equipment. The dam would remain in place and current reservoir levels would be maintained. Additional capital improvements would be required for long term compliance with dam safety regulations.

Surrender and Decommission - Partial Removal

The partial removal scenario evaluates the partial removal of the dam by reducing the earthen dam structure while fully removing the powerhouse and generation facilities. This reduction would create a sufficient breach to pass the 100-year flood through the reestablished river channel, ensuring that the incremental rise at the dam site would be less than 0.10 foot. This scenario also considers the potential to maintain some form of upstream reservoir system while developing a new weir control structure.

This structure would be designed to fall under state regulations (Natural Resources and Environmental Protection Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir and to prevent the proliferation of invasive species such as the sea lampreys. Exposed sediments and newly exposed shoreline would be stabilized and re-vegetated.

Schematics for the partial removal scenario for the reservoir reservation for each dam structure are provided in their respective appendices of A through F.

Surrender and Decommission - Full Removal

The full removal scenario evaluates the complete removal of the dam and reservoirs. The reservoirs would be drained, powerhouse/generation facilities, earthen dam, concrete spillway, tailrace and retaining structures fully removed, and the upstream channel and floodplain restored to pre-dam conditions. To minimize the transport and improve stabilization of the sediment within the reservoir, the reservoir would be drawn down in a controlled manner. Hydraulic dredging would be performed to approximate the river's original meander to allow the river to re-establish its course through the current reservoir. Contaminated sediments, if present, would be hauled off site and disposed of properly.

Schematics for the full removal scenario for the reservoir reservation for each dam structure are provided in their respective appendices of A through F.

3.2 LIMITATIONS

- Prior costs provided by Consumers for these scenarios and developed by Kiewit Corporation in 2022, as available, and Mead & Hunt (M&H) in 2021 were used as the foundation of these estimates. Sequencing of work follows the descriptions as detailed by M&H with additional measures incorporated following removal as part of the reservoir restoration. Estimates were supplemented and expanded based on similar experiences from other applicable dam removal projects.
- Information related to sediment volumes and characterization are estimated and assumed based on watershed research for potential hazardous contamination. As no data is available at this time, there is significant risk associated with the uncertainty to the volumes and level of contamination for management. Unless documentation of known hazardous spills were identified for the watershed, it was considered as a mix of non-

contaminated and contaminated non-hazardous sediments for removal and disposal, as detailed herein. Sediment investigations would occur after a decision to surrender and decommission were approved.

- These estimates are based on Q4 2022 dollars at the time of preparation.
- Cost estimates, by nature, are as best as the information available at the time of preparation. Estimates should be reconsidered and updated as new information is obtained and as market conditions change.
- Additional assumptions and limitations considered for each cost item to derive the presented unit pricing and quantity are detailed herein.

4 COST ESTIMATE SUMMARY

4.1 CLASS ESTIMATES

Although hydropower costs are highly site-specific with many factors contributing to cost uncertainty, costs accuracy is generally assumed to increase as project development nears completion. As such construction stage cost estimates are necessarily considered the most accurate and are quantitatively defined as such by Association for the Advancement of Cost Engineering (AACE). The level of information or considerations prepared for this independent evaluation, with limitations, would be considered as Class 5 estimate per AACE.

4.1.1 CLASS 5 ESTIMATE

This is known as the rough order of magnitude (ROM) estimate. It is used for the initial screening projects for capital expenditure planning. Since several projects are initially available, estimating each would require a tremendous amount of time and effort. Given the limited preparation, ballpark figures are usually accepted to make business plan projections. Class 5 estimates are drawn from limited information which is about 0 to 2% of the project definition. The information may be nothing more than a basic description of the plant or process, capacity, and location. That is why its accuracy ranges -50% on the low side and +100%on the high side.

Class 5 cost estimate accuracy range: -50% to +100%

Stochastic cost estimating methods are used for obtaining a Class 5 estimate. Examples of these are cost/capacity curves, rule of six-tenths, Lang factor method, scale of operation factors, and cost indices. These techniques use parametric cost estimation methods to deduce the total cost of a given project.

4.2 COST ESTIMATE SUMMARIES

Costs for each surrender scenario were calculated for (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. Detailed descriptions for each item under each scenario are provided below.

All units used in the cost estimate are U.S. Standard and all costs are in US Dollars (4th Quarter 2022 levels) if prepared by WSP. Pricing evaluated and utilized by the previous studies are based on costs at the time of their preparation (e.g. 2021 and early 2022). No price escalation was applied due to proximity in date of preparation and class 5 level estimate being prepared. The conceptual decommissioning cost estimates for each scenario by dam location are included in Appendix A through F.

4.2.1 QUANTITIES AND UNIT COSTS

Quantities of pieces of equipment and/or bulk material commodities used in the cost estimates were intended to be reasonable and representative of projects of this type. Material quantities were prepared by M&H in 2021 for categorial items included within their estimate. As appropriate, WSP simplified unit measurements and unit pricing for subject activities. For additional activity items incorporated by WSP, quantities were estimated from the schematic renderings prepared for each site and included within Appendix A through F, as detailed below. Upon determining corrective unit quantities and unit costs, cost components for each activity were determined by the multiplication of the unit quantity by unit cost, rounded to the nearest whole dollar.

4.2.2 UNCERTAINTY AREAS

This estimate will be based on similar experiences from other projects. Therefore, some specific information about each site is unknown. Additional studies would be needed to determine physical and chemical characteristics of soils and

sediments, potential costs required to manage and dispose of potentially contaminated sediments upstream of the structures, type of vegetation and presence of non-native species, archaeological resources and historic structures, hydrology and hydraulic characteristics, as well as ecology and biology upstream and downstream of the structures.

4.2.3 MIO DAM COST ESTIMATE ACTIVITIES

Table 4.1 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.1 Mio Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Remove Lines from Plant to Substation		X	X
	Move Distribution Lines from Plant Bus		X	X
Decommissioning and Demolition	Remove Security Fencing		X	X
	Remove Plant Access Road		X	X
	Remove Storage Building		X	X
	Remove Septic Tank / Drain Field		X	X
	Removal of Right Downstream Fishing Pier: Reinforced Concrete Demolition		X	X
	Removal of Right Downstream Fishing Pier: Sheet Piling Removal		X	X
	Remove Piezometers		X	X

	Construction Management, Biological Monitoring and O&M	X	X	X
Contingency	Cost Contingency	X	X	X

Remove Lines from Plant to Substation

Price per linear foot was taken from the M&H estimate for removal lines from the plant to the substation. The partial and full removal options assume that the Mio Plant would be demolished and therefore, electricity would no longer be required.

Move Distribution Lines from Plant Bus

Price per linear foot was taken from the M&H estimate to move distribution lines from plant bus. The partial and full removal options assume that the Mio Plant would be demolished and therefore, electricity would no longer be required.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary.

Remove Storage Building

Lump sum cost was taken from the M&H estimate. The onsite storage building will be demolished and disposed of offsite for all three scenarios.

Remove Septic Tank/Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Removal of Right Downstream Fishing Pier: Reinforced Concrete Demolition

Cubic yard unit price was taken from the M&H estimate. Per the M&H estimate, the scope of work for both the partial and full removal scenarios includes demolition of the right downstream fishing pier, including the reinforced concrete substructure. All the demolished material would be transported offsite for disposal in a designated landfill area.

Removal of Right Downstream Fishing Pier: Sheet Piling Removal

Cost per square foot was taken from the M&H estimate. Under the full removal option, the right downstream fishing pier sheet pilling would be removed entirely. This activity accounts for sheet pile cutoff with all material disposed of offsite.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 26 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove Turbines

Provided as a price per ton was taken from the M&H estimate. Under the partial and full removal options, turbines would be removed during decommissioning and transported to an off-site disposal area.

Remove Generators

Price per ton was taken from the M&H estimate. Under the partial and full removal options, generators would be removed during decommissioning and transported to an off-site disposal area.

Remove Cranes

Price per ton was taken from the M&H estimate. Under the partial and full removal options, cranes would be removed during decommissioning and transported to an off-site disposal area.

Remove Trash Rack Rake System

Price per ton was taken from the M&H estimate. Under the partial and full removal options, trash racks rake system would be removed during decommissioning and transported to an off-site disposal area.

Remove Fixtures

Price per ton was taken from the M&H estimate. Under the partial and full removal options, fixtures would be removed during decommissioning and transported to an off-site disposal area.

Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, electrical equipment would be removed during decommissioning and transported to an off-site disposal area.

Reinforced Concrete/Masonry Demolition Including Spill Tubes, Intake/Tailrace, Retaining Wall & Aprons

Cubic yard unit price was taken from the M&H estimate. Per the M&H estimate, the scope of work for both the partial and full removal scenarios includes demolition of the roof, masonry superstructure, reinforced concrete substructure and foundation, substation, gates and valves, tailrace guide walls and aprons, and upstream and downstream sheet pile cutoffs. All the demolished material would be transported offsite for disposal in a designated landfill area.

Remove Trash Racks

Price per ton was taken from the M&H estimate. Under the partial and full removal options, trash racks would be removed during decommissioning and transported to an off-site disposal area.

Remove Valves

Price per ton was taken from the M&H estimate. Under the partial and full removal options, valves would be removed during decommissioning and transported to an off-site disposal area.

Remove Trash Rack Platforms

Price per ton was taken from the M&H estimate. Under the partial and full removal options, trash racks platforms would be removed during decommissioning and transported to an off-site disposal area.

Remove Gates

Price per ton was taken from the M&H estimate. Under the partial and full removal options, gates would be removed during decommissioning and transported to an off-site disposal area.

Remove Hoist Rail

Price per ton was taken from the M&H estimate. Under the partial and full removal options, hoist rails would be removed during decommissioning and transported to an off-site disposal area.

Remove Spillway Hoist

Price per ton was taken from the M&H estimate. Under the partial and full removal options, spillway hoist would be removed during decommissioning and transported to an off-site disposal area.

Drain 661-Acre Reservoir

Lump sum cost was taken from the M&H cost estimate. Under the partial and complete removal options, the reservoir would be drained in a controlled manner through the powerhouse during removal of the powerhouse structure, intake tower, penstocks, and a section of the embankment dam. The removal will be staged and the effect of lowering the reservoir on project wetlands will be monitored monthly throughout the process. Once these elements of the project have been removed, the embankment dam would be breached sufficiently to allow the 100-year-flood flow to pass through the natural river channel located to the right of the powerhouse structure.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Cubic yard unit price was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall - Sheet Piling Removal

Cost per square foot was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for sheet pile cutoff with all material disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal, a 300-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging

Cubic yard unit price was taken from the M&H estimate. It is assumed that the 300-foot-wide main channel will be re-established with limited dredging. According to M&H's opinion, approximately 1,048,407 cubic yards of material will need to be removed to clear fine-grain sediments and re-establish the channel where necessary beyond the pilot channel. This amount is prorated at 85% to account for limited dredging within the new impoundment for the partial removal. For secondary tributary connections, which total 36,000 linear feet, it is assumed that dredging will occur at a width of 50-feet and an average depth of 4-feet, resulting in an estimated 300,000 cubic yards of material to be removed.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Excavation

Cubic yard unit price was taken from the M&H estimate. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Reinforced Concrete Demo

Cubic yard unit price was taken from the M&H estimate. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This item includes the demolition of reinforced concrete associated with this removal. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Sheet Piling Removal

Cost per square foot was taken from the M&H estimate. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This activity accounts for sheet pile cutoff with all material disposed of offsite.

Leave Powerhouse Intact

Lump sum cost from M&H cost estimate. The powerhouse structure would be left in place under the non-power operation option. Once the electrical generating equipment had been removed, water intake into the power plant would be plugged with concrete and the power conduits beneath the powerhouse would be filled with sand.

Remove or Lay-Up Equipment: Disable Generating Capacity

Lump sum cost was taken from the M&H cost estimate. Under the non-power operation option, the turbine-generator would be disabled, and all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance would be decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as CFCs and other hazardous materials routinely associated with the plant's electromechanical equipment.

Remove or Lay-Up Equipment: Remove Electrical Equipment

Lump sum cost was taken from the M&H cost estimate. Under the non-power operation option, the turbine-generator would be disabled, and all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance would be decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as CFCs and other hazardous materials routinely associated with the plant's electromechanical equipment.

Remove Contaminated Sediments – Removal

Cubic yard unit price was taken from the M&H estimate. Consideration of dredging operation only for removal and loading into a disposal truck of an initial layer of contaminated non-hazardous sediments at the onset of removal. Quantity considers a 12-inch layer of non-hazardous contaminated materials is removed from 10% of the reservoir area for disposal at a registered landfill accepting non-hazardous sediments for both the partial and full removal scenarios.

Remove Contaminated Sediments – Disposal

Unit cost consideration for transportation and disposal fee of non-hazardous contaminated sediments at an offsite facility accepting material.

Salvage

Lump sum cost derived from M&H estimate for salvage pricing as detailed in the M&H estimate report. Due to its lower salvage value at the time of their estimate and the level of this cost estimate, pricing for updated market value in salvage rates was not evaluated/applied as it was expected to rebound, which would reduce overall costs considered.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container, 1-2' high.

Apply Erosion Control Measures - Silt Fence

Price per linear foot and unit quantity was estimated based on similar projects. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 20% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the AuSable River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 80% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the AuSable River, as well as both banks for all tributary lengths.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Grading & Surface Preparation/Amendments

WSP added cost for grading and surface preparation/amendments for newly exposed sediments within the reservoir for floodplain restoration.

Channel Creation - Riffle Section at Downstream Tie In

This item involves the placement of river rock along a portion at the downstream limits of work for the riffle bed reconstruction. It is assumed that the riffle section will be 200-feet-wide, 600-feet-long, and 2-feet-deep for the full removal and partial removal. The river rock will be strategically placed to enhance the stability and functionality of the riffle, promoting better water flow and habitat conditions.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot-drop and 3-foot-footer) and 4-foot-width.

Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 20-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 9-vertical-foot drop in water height is considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost derived from M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Owner's Cost

An owner's cost of 15% of the construction subtotal, less the contaminated material disposal cost, was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $260,565 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

oval scenario, 3.5% of the construction subtotal (excluding contaminated sediment disposal costs) with an for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social d be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal (excluding contaminated sediment disposal costs) was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring and O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal (less contaminated sediment disposal costs) were applied. These costs may be variable as the design develops and permit stipulations are identified.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.4 ALCONA DAM COST ESTIMATE ACTIVITIES

Table 4.2 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.2 Alcona Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Remove Lines from Plant to Substation		X	X
	Move Distribution Line from Plant Bus		X	X
	Remove Security Fencing		X	X
	Remove Plant Access Road		X	X

Remove Lines from Plant to Substation

Price per linear foot was taken from the M&H estimate for removal lines from the plant to the substation. The partial and full removal options assume that the Alcona Plant would be demolished and therefore, electricity would no longer be required.

Move Distribution Lines from Plant Bus

Price per linear foot was taken from the M&H estimate to move distribution lines from plant bus. The partial and full removal options assume that the Alcona Plant would be demolished and therefore, electricity would no longer be required.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary. Work includes approximately 600 feet of the access road to be removed with the remaining left to provide access to the relocated overhead distribution line.

Plug and Abandon Artesian Wells

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 24 of the artesian wells would be either excavated and removed or abandoned and

capped below grade.

Remove Septic Tank / Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 10 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove Turbines

Price per ton was taken from the M&H estimate. Under the partial and full removal options, turbines would be removed during decommissioning and transported to an off-site disposal area.

Remove Generators

Price per ton was taken from the M&H estimate. Under the partial and full removal options, generators would be removed during decommissioning and transported to an off-site disposal area.

Remove Cranes

Price per ton was taken from the M&H estimate. Under the partial and full removal options, cranes would be removed during decommissioning and transported to an off-site disposal area.

Remove Fixtures

Price per ton was taken from the M&H estimate. Under the partial and full removal options, fixtures would be removed during decommissioning and transported to an off-site disposal area.

Remove Hoists

Price per ton was taken from the M&H estimate. Under the partial and full removal options, hoists would be removed during decommissioning and transported to an off-site disposal area.

Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, electrical equipment would be removed during decommissioning and transported to an off-site disposal area.

Reinforced Concrete/Masonry Demolition Including Spill Tubes, Intake/Tailrace, Retaining Wall & Aprons

Cubic yard unit price was taken from the M&H estimate. Per the M&H estimate, the scope of work for both the partial and full removal scenarios will include demolition of the roof, masonry superstructure, reinforced concrete substructure and foundation, substation, gates and valves, tailrace guide walls and aprons, and upstream and downstream sheet pile cutoffs. All the demolished material would be transported offsite for disposal in a designated landfill area.

Remove Trash Racks

Price per ton was taken from the M&H estimate. Under the partial and full removal options, trash racks would be removed during decommissioning and transported to an off-site disposal area.

Remove Valves

Price per ton was taken from the M&H estimate. Under the partial and full removal options, valves would be removed during decommissioning and transported to an off-site disposal area.

Remove Gates

Price per ton was taken from the M&H estimate. Under the partial and full removal options, gates would be removed during decommissioning and transported to an off-site disposal area.

Drain 1,006-Acre Reservoir

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate includes draining the reservoir in a

controlled manner through the powerhouse structure as it is demolished and removed in a staged process. The staged removal of the powerhouse would require the installation of a stoplog bulkhead frame upstream of one of the powerhouse bays. The bulkhead would allow the demolition of the upstream face of one of the powerhouse bays while maintaining the discharge capacity of the remaining spill tube and intake gate. Once the reservoir has been lowered to the powerhouse foundation level using the bulkhead stoplogs, the embankment dam would be breached to allow flows to pass through the natural river channel located to the left of the powerhouse. With the river diverted through the breached section of the embankment, the remaining powerhouse bays, guide walls and aprons would be removed.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. The earth dams would be completely removed under the full removal scenario. It is assumed excavated earth material will stay onsite to reflect the unit price prepared by M&H.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Cubic yard unit price was taken from the M&H estimate. As part of the earth dam removal, the concrete core wall will be demolished and disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall - Sheet Piling Removal

Square foot unit price was taken from the M&H estimate. This activity accounts for the sheet pile cutoff, in which all of the sheet pile wall as part of the core wall will be removed and disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal, a 200-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal scenarios, this work includes additional hydraulic dredging of the reservoir area beyond the 200-foot-wide pilot channel during the drawdown process to restore the floodplain characteristics of the AuSable River. Unit quantities derived from M&H estimate and does not take into consideration additional volume removed for contaminated non-hazardous material. All material is considered non-contaminated and reused onsite. Following removal of the dam.

For the partial removal scenario, WSP considered an 85% quantity reduction in volume removed based on installation of a replacement weir system and upstream reservoir design to maintain a smaller impounded water level.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Excavation

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of the earth dam and core wall adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Reinforced Concrete Demo

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of the earth dam and core wall adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Sheet Piling Removal

Square foot unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of the

embankment dam and core wall adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for sheet pile cutoff with all material disposed of offsite.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H cost estimate. The powerhouse structure would be left in place under the non-power operation option. Once the electrical generating equipment had been removed, water intake into the power plant would be plugged with concrete and the power conduits beneath the powerhouse would be filled with sand.

Remove or Lay-Up Equipment: Disable Generating Capacity

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the generating capacity with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Remove or Lay-Up Equipment: Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the electrical equipment with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Modify Spill Tubes to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity details modifications to the operation of the powerhouse spill tubes would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Remove Contaminated Sediments – Removal

Cubic yard unit price was taken from the M&H estimate. Consideration of dredging operation only for removal and loading into a disposal truck of an initial layer of contaminated non-hazardous sediments at the onset of removal. Quantity considers a 12-inch layer of non-hazardous contaminated materials is removed from the reservoir area for disposal at a registered landfill accepting non-hazardous sediments for both the partial and full removal scenarios.

Remove Contaminated Sediments – Disposal

Unit cost consideration for transportation and disposal fee of non-hazardous contaminated sediments at an offsite facility accepting material.

Salvage

Lump sum cost derived from M&H estimate for salvage pricing as detailed in the M&H estimate report. Due to its lower salvage value at the time of their estimate and the level of this cost estimate, pricing for updated market value in salvage rates was not evaluated/applied as it was expected to rebound, which would reduce overall costs considered.

Spillway Site Restoration: Planting and Seeding

WSP derived cost for providing permanent seeding of restored spillway area for stabilization of sediment/soils and reservoir restoration, and WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils

and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Apply Erosion Control Measures - Silt Fence

Price per linear foot was adjusted based on similar project and unit quantity was derived from M&H estimate. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 15% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the AuSable River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 85% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the AuSable River, as well as both banks for all tributary lengths.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Grading & Surface Preparation/Amendments

WSP added cost for grading and surface preparation/amendments for newly exposed sediments within the reservoir for floodplain restoration.

Channel Creation - Riffle Section at Downstream Tie In

WSP derived cost for performing additional channel restoration for a length immediately at and above the dam that includes imported rock. For the partial removal, a 600-foot-length is considered upstream of the revised water impounded area. For the full removal, a 1250-foot-length is considered for the dam footprint extending to the same termination point as the partial removal.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot-drop and 3-foot-footer) and 4-foot-width.

Installation of Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 26-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 6-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to

maintain small amounts of upstream ponding.

Spiral Case Enlargement

Lump sum cost derived from M&H estimate. M&H scope of work for this cost activity details modifications during the Stage 1 drawdown, the turbine spiral case would be enlarged to divert flows during Stage 2.

Owner's Cost

An owner's cost of 15% of the construction subtotal, less contaminated sediment disposal costs, was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $317,970 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal (excluding contaminated sediment disposal costs) with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal (excluding contaminated sediment disposal costs) was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring and O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal (excluding contaminated sediment disposal costs) were applied. These costs may be variable as the design develops and permit stipulations are identified.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.5 LOUD DAM COST ESTIMATE ACTIVITIES

Table 4.3 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.3 Loud Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Remove Lines from Plant to Substation		X	X
Decommissioning and Demolition	Remove Security Fencing		X	X

Remove Lines from Plant to Substation

Price per linear foot was taken from the M&H estimate for removal lines from the plant to the substation. The partial and full removal options assume that the Loud Plant would be demolished and therefore, electricity would no longer be required.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary. Work includes approximately 1,000-feet of the access road to be removed with the remaining left to provide access to the relocated overhead distribution line.

Remove Septic Tank / Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 15 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove Turbines

Price per ton was taken from the M&H estimate. Under the partial and full removal options, turbines would be removed during decommissioning and transported to an off-site disposal area.

Remove Generators

Price per ton was taken from the M&H estimate. Under the partial and full removal options, generators would be removed during decommissioning and transported to an off-site disposal area.

Remove Cranes

Price per ton was taken from the M&H estimate. Under the partial and full removal options, cranes would be removed during decommissioning and transported to an off-site disposal area.

Remove Fixtures

Price per ton was taken from the M&H estimate. Under the partial and full removal options, fixtures would be removed during decommissioning and transported to an off-site disposal area.

Remove Hoists

Price per ton was taken from the M&H estimate. Under the partial and full removal options, hoists would be removed during decommissioning and transported to an off-site disposal area.

Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, electrical equipment would be removed during decommissioning and transported to an off-site disposal area.

Reinforced Concrete/Masonry Demolition Including Spill Tubes, Intake/Tailrace, Retaining Wall & Aprons

Cubic yard unit price was taken from the M&H estimate. Per the M&H estimate, the scope of work for both the partial and full removal scenarios will include demolition of the roof, masonry superstructure, reinforced concrete substructure and foundation, substation, gates and valves, tailrace guide walls and aprons, and upstream and downstream sheet pile cutoffs. All the demolished material would be transported offsite for disposal in a designated landfill area.

Remove Trash Racks

Price per ton was taken from the M&H estimate. Under the partial and full removal options, trash racks would be removed during decommissioning and transported to an off-site disposal area.

Remove Valves

Price per ton was taken from the M&H estimate. Under the partial and full removal options, valves would be removed during decommissioning and transported to an off-site disposal area.

Remove Gates

Price per ton was taken from the M&H estimate. Under the partial and full removal options, gates would be removed during decommissioning and transported to an off-site disposal area.

Demolish And Remove Spillway Including Concrete Weir and Apron: Reinforced Concrete Demo

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate for this cost activity include demolition and removal of the spillway structure, including gates, bridge, concrete weir, and apron. For the partial removal, the

spillway guide walls, weir and apron would remain in place with gates removed. For the full removal, the demolition would be complete and include approach guide walls and apron, stilling basin weir, and tailrace guide walls and apron. The upstream sheet pile cutoff would also be removed to below the natural river channel level. All demolished material would be transported offsite for disposal in a designated landfill/recycled (salvage).

Demolish And Remove Powerhouse Generator Hall

Cubic yard unit price was taken from the M&H estimate. The powerhouse generator hall would be completely removed under the full removal scenario. As part of the powerhouse generator hall removal, the hall will be demolished and disposed of offsite.

Remove Spillway Gates

Price per ton was taken from the M&H estimate. Under the partial and full removal options, spillway gates would be removed during decommissioning and transported to an off-site disposal area.

Remove Spillway Hoists

Price per ton was taken from the M&H estimate. Under the partial and full removal options, spillway hoists would be removed during decommissioning and transported to an off-site disposal area.

Drain 743 -Acre Reservoir

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate includes draining the reservoir in a controlled manner through the powerhouse and spillway structure as they are demolished and removed in a staged process. The staged removal of the spillway would require that a steel sheet pile, gravel-filled cellular cofferdam with removable stoplogs, be placed upstream of the spillway. This cofferdam would allow the demolition of the entire spillway while regulating the diversion of river flows through the powerhouse structure. Once the reservoir has been lowered to the spillway foundation slab, the cofferdam would be removed to allow flows to be diverted through the previous spillway area to the natural river channel, and the remaining powerhouse bays, guide walls, and aprons would be removed. Once the powerhouse and spillway structures have been removed, the removal of the embankment dam would be completed. WSP price considers cofferdam and diversion for both scenarios and concrete stoplogs.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. The earth dams would be completely removed under the full removal scenario. It is assumed excavated earth material will stay onsite to reflect the unit price prepared by M&H.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Cubic yard unit price was taken from the M&H estimate. As part of the earth dam removal, the concrete core wall will be demolished and disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel

Cubic yard unit price and quantity was taken from the M&H estimate. For both the partial and full removal, a 300-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal scenarios, this work includes additional hydraulic dredging of the reservoir area beyond the 200-foot-wide pilot channel during the drawdown process to restore the floodplain characteristics of the AuSable River. Unit quantities derived from M&H estimate and does not take into consideration additional volume removed for contaminated non-hazardous material. All material is considered non-contaminated and reused onsite. Following removal of the dam.

For the partial removal scenario, WSP considered an 85% quantity reduction in volume removed based on installation of a replacement weir system and upstream reservoir design to maintain a smaller impounded water level.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Excavation

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Reinforced Concrete Demo

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H cost estimate. The powerhouse structure would be left in place under the non-power operation option. Once the electrical generating equipment had been removed, water intake into the power plant would be plugged with concrete and the power conduits beneath the powerhouse would be filled with sand.

Remove or Lay-Up Equipment: Disable Generating Capacity

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the generating capacity with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Remove or Lay-Up Equipment: Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the electrical equipment with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Salvage

Lump sum cost was taken from the M&H estimate for salvage pricing as detailed in the M&H estimate report. Due to its lower salvage value at the time of their estimate and the level of this cost estimate, pricing for updated market value in salvage rates was not evaluated/applied as it was expected to rebound, which would reduce overall costs considered.

Apply Erosion Control Measures - Silt Fence

Price per linear foot was adjusted based on similar projects and unit quantity was taken from the M&H estimate. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials

(accounted for in other cost activities) onsite.

Grading & Surface Preparation/Amendments

WSP added cost for grading and surface preparation/amendments for newly exposed sediments within the reservoir for floodplain restoration.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 20% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the AuSable River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 80% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the AuSable River, as well as both banks for all tributary lengths.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Channel Creation - Riffle Section at Downstream Tie In

WSP derived cost for performing additional channel restoration for a length immediately at and above the dam that includes imported rock. For the partial removal, a 300-foot-length is considered upstream of the revised water impounded area. For the full removal, a 600-foot-length is considered for the dam footprint extending to the same termination point as the partial removal.

Installation of Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 26-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 6-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot drop and 3-foot footer) and 4-foot width.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost derived from M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Owner's Cost

An owner’s cost of 15% of the construction subtotal was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $225,289 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring and O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal were applied. These costs may be variable as the design develops and permit stipulations are identified.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.6 FIVE CHANNELS DAM COST ESTIMATE ACTIVITIES

Table 4.4 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.4 Five Channels Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Remove Lines from Plant to Substation		X	X
Decommissioning and Demolition	Remove Security Fencing		X	X
	Remove Office Building / Warehouses	X	X	X

	Construction Management, Biological Monitoring and O&M	X	X	X
Contingency	Cost Contingency	X	X	X

Remove Lines from Plant to Substation

Price per linear foot was taken from the M&H estimate for removal lines from the plant to the substation. The partial and full removal options assume that the Five Channels Plant would be demolished and therefore, electricity would no longer be required.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Office Buildings/Warehouses

Lump sum cost was taken from the M&H estimate. The onsite office buildings and warehouses will be demolished and disposed of offsite for all three scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary. Work includes approximately 635-station of the access road to be removed.

Remove Septic Tank/Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 10 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove Turbines

Price per ton was taken from the M&H estimate. Under the partial and full removal options, turbines would be removed during decommissioning and transported to an off-site disposal area.

Remove Generators

Price per ton was taken from the M&H estimate. Under the partial and full removal options, generators would be removed during decommissioning and transported to an off-site disposal area.

Remove Cranes

Price per ton was taken from the M&H estimate. Under the partial and full removal options, cranes would be removed during decommissioning and transported to an off-site disposal area.

Remove Fixtures

Price per ton was taken from the M&H estimate. Under the partial and full removal options, fixtures would be removed during decommissioning and transported to an off-site disposal area.

Remove Hoists

Price per ton was taken from the M&H estimate. Under the partial and full removal options, hoists would be removed during decommissioning and transported to an off-site disposal area.

Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, electrical equipment would be removed during decommissioning and transported to an off-site disposal area.

Reinforced Concrete/Masonry Demolition Including Intake/Tailrace, Retaining Wall & Aprons

Cubic yard unit price was taken from the M&H estimate. Per the M&H estimate, the scope of work for both the partial and full removal scenarios will include demolition of the roof, masonry superstructure, reinforced concrete substructure and foundation, substation, gates and valves, tailrace guide walls and aprons, and upstream and downstream sheet pile cutoffs. All the demolished material would be transported offsite for disposal in a designated landfill area.

Remove Trash Racks

Price per ton was taken from the M&H estimate. Under the partial and full removal options, trash racks would be removed during decommissioning and transported to an off-site disposal area.

Remove Valves

Price per ton was taken from the M&H estimate. Under the partial and full removal options, valves would be removed during decommissioning and transported to an off-site disposal area.

Remove Gates

Price per ton was taken from the M&H estimate. Under the partial and full removal options, gates would be removed during decommissioning and transported to an off-site disposal area.

Demolish And Remove Spillway Including Concrete Weir and Apron: Reinforced Concrete Demo

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate for this cost activity include demolition and removal of the spillway structure, including gates, bridge, concrete weir, and apron. For the partial removal, the spillway guide walls, weir and apron would remain in place with gates removed. For the full removal, the demolition would be complete and include approach guide walls and apron, stilling basin weir, and tailrace guide walls and apron. The upstream sheet pile cutoff would also be removed to below the natural river channel level. All demolished material would be transported offsite for disposal in a designated landfill/recycled (salvage).

Remove Spillway Gates

Price per ton was taken from the M&H estimate. Under the partial and full removal options, spillway gates would be removed during decommissioning and transported to an off-site disposal area.

Remove Hoist Rail/Platform

Price per ton was taken from the M&H estimate. Under the partial and full removal options, hoist rail and platform would be removed during decommissioning and transported to an off-site disposal area.

Remove Spillway Hoists

Price per ton was taken from the M&H estimate. Under the partial and full removal options, spillway hoists would be removed during decommissioning and transported to an off-site disposal area.

Drain 212 -Acre Reservoir

Lump sum cost was taken from the M&H cost estimate. Under the partial and complete removal options, the reservoir would be drained in a controlled manner through the powerhouse during removal of the powerhouse structure, intake tower, penstocks, and a section of the embankment dam. The removal will be staged and the effect of lowering the reservoir on project wetlands will be monitored monthly throughout the process. Once these elements of the project have been removed, the embankment dam would be breached sufficiently to allow the 100-year-flood flow to pass through the natural river channel located to the right of the powerhouse structure.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Cost per cubic yard was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal, a 300-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging

Cubic yard unit price was taken from the M&H estimate. It is assumed that the 200-foot-wide main channel will be re-established with limited dredging. According to M&H's opinion, approximately 749,000 cubic yards of material will need to be removed to clear fine-grain sediments and re-establish the channel where necessary beyond the pilot channel. This amount is prorated at 85% to account for limited dredging within the new impoundment for the partial removal. For secondary tributary connections, which total 400 linear feet, it is assumed that dredging will occur at a width of 50-feet and an average depth of 4-feet, resulting in an estimated 2,970 cubic yards of material to be removed.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Excavation

Cubic yard unit price was taken from the M&H estimate. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Reinforced Concrete Demo

Cubic yard unit price was taken from the M&H estimate. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This item includes the demolition of reinforced concrete associated with this removal. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H cost estimate. The powerhouse structure would be left in place under the non-power operation option. Once the electrical generating equipment had been removed, water intake into the power plant would be plugged with concrete and the power conduits beneath the powerhouse would be filled with sand.

Remove or Lay-Up Equipment: Disable Generating Capacity

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the generating capacity with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Remove or Lay-Up Equipment: Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the electrical equipment with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Salvage

Lump sum cost was taken from the M&H estimate for salvage pricing as detailed in the M&H estimate report. Due to its lower salvage value at the time of their estimate and the level of this cost estimate, pricing for updated market value in salvage rates was not evaluated/applied as it was expected to rebound, which would reduce overall costs considered.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Apply Erosion Control Measures - Silt Fence

Price per linear foot was adjusted based on similar projects and unit quantity derived from M&H estimate. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 20% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the AuSable River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 80% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the AuSable River, as well as both banks for all tributary lengths.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Grading & Surface Preparation/Amendments

WSP added cost for grading and surface preparation/amendments for newly exposed sediments within the reservoir for floodplain restoration.

Channel Creation - Riffle Section at Downstream Tie In

This item involves the placement of river rock along a portion at the downstream limits of work for the riffle bed reconstruction. It is assumed that the riffle section will be 200-feet-wide, 890-feet-long, and 2-feet-deep for the full removal and the partial removal. The river rock will be strategically placed to enhance the stability and functionality of the riffle, promoting better water flow and habitat conditions.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot-drop and 3-foot-footer) and 4-foot-width.

Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 95-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 9-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Owner's Cost

An owner’s cost of 15% of the construction subtotal was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $185,853 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal was applied. It is assumed the price for the

environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring and O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal were applied. These costs may be variable as the design develops and permit stipulations are identified.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.7 COOKE DAM COST ESTIMATE ACTIVITIES

Table 4.5 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.5 Cooke Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Remove Lines from Plant to Substation		X	X

generation scenario only, includes disabling the electrical equipment with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Salvage

Lump sum cost was taken from the M&H estimate for salvage pricing as detailed in the M&H estimate report. Due to its lower salvage value at the time of their estimate and the level of this cost estimate, pricing for updated market value in salvage rates was not evaluated/applied as it was expected to rebound, which would reduce overall costs considered.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Apply Erosion Control Measures - Silt Fence

Price per linear foot and unit quantity was taken from the M&H estimate. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 20% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the AuSable River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 80% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the AuSable River, as well as both banks for all tributary lengths.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Grading & Surface Preparation/Amendments

WSP added cost for grading and surface preparation/amendments for newly exposed sediments within the reservoir for floodplain restoration.

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
	Construction Management, Biological Monitoring and O&M	X	X	X
Contingency	Cost Contingency	X	X	X

Remove Lines from Plant to Substation

Price per linear foot was taken from the M&H estimate for removal lines from the plant to the substation. The partial and full removal options assume that the Cooke Plant would be demolished and therefore, electricity would no longer be required.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary. Work includes approximately 600 feet of the access road to be removed with the remaining left to provide access to the relocated overhead distribution line.

Remove Septic Tank / Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Piezometers

Price per each Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 7 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove Turbines

Price per ton was taken from the M&H estimate. Under the partial and full removal options, turbines would be removed during decommissioning and transported to an off-site disposal area.

Remove Generators

Price per ton was taken from the M&H estimate. Under the partial and full removal options, generators would be removed during decommissioning and transported to an off-site disposal area.

Remove Cranes

Price per ton was taken from the M&H estimate. Under the partial and full removal options, cranes would be removed during decommissioning and transported to an off-site disposal area.

Remove Trash Rack Rake System

Price per ton was taken from the from the M&H estimate. Under the partial and full removal options, trash racks rake system would be removed during decommissioning and transported to an off-site disposal area.

Remove Fixtures

Price per ton was taken from the M&H estimate. Under the partial and full removal options, fixtures would be removed during decommissioning and transported to an off-site disposal area.

Remove Powerhouse Hoists

Price per ton was taken from the M&H estimate. Under the partial and full removal options, powerhouse hoists would be removed during decommissioning and transported to an off-site disposal area.

Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, electrical equipment would be removed during decommissioning and transported to an off-site disposal area.

Reinforced Concrete/Masonry Demolition Including Spill Tubes, Intake/Tailrace, Retaining Wall & Aprons

Cubic yard unit price was taken from the M&H estimate. Per the M&H estimate, the scope of work for both the partial and full removal scenarios includes demolition of the roof, masonry superstructure, reinforced concrete substructure and foundation, substation, gates and valves, tailrace guide walls and aprons, and upstream and downstream sheet pile cutoffs. All the demolished material would be transported offsite for disposal in a designated landfill area.

Remove Valves

Price per ton was taken from the M&H estimate. Under the partial and full removal options, valves would be removed during decommissioning and transported to an off-site disposal area.

Remove Trash Racks

Price per ton was taken from the M&H estimate. Under the partial and full removal options, trash racks would be removed during decommissioning and transported to an off-site disposal area.

Remove Powerhouse Gates

Price per ton was taken from the M&H estimate. Under the partial and full removal options, powerhouse gates would be removed during decommissioning and transported to an off-site disposal area.

Demolish And Remove Spillway Including Concrete Weir and Apron: Reinforced Concrete Demo

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate for this cost activity include demolition and removal of the spillway structure, including gates, bridge, concrete weir, and apron. For the partial removal, the spillway guide walls, weir and apron would remain in place with gates removed. For the full removal, the demolition would be complete and include approach guide walls and apron, stilling basin weir, and tailrace guide walls and apron. The upstream sheet pile cutoff would also be removed to below the natural river channel level. All demolished material would be transported offsite for disposal in a designated landfill/recycled (salvage).

Remove Spillway Gates

Price per ton was taken from the M&H estimate. Under the partial and full removal options, spillway gates would be removed during decommissioning and transported to an off-site disposal area.

Remove Spillway Hoists

Price per ton was taken from the M&H estimate. Under the partial and full removal options, spillway hoists would be removed during decommissioning and transported to an off-site disposal area.

Drain 1,627-Acre Reservoir

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate includes draining the reservoir in a controlled manner through the powerhouse and spillway structure as they are demolished and removed in a staged process. The staged removal of the spillway would require that a steel sheet pile, gravel-filled cellular cofferdam with removable stoplogs, be placed upstream of the spillway. This cofferdam would allow the demolition of the entire spillway while regulating the diversion of river flows through the powerhouse structure. Once the reservoir has been lowered to the spillway foundation slab, the cofferdam would be removed to allow flows to be diverted through the previous spillway area to the natural river channel, and the remaining powerhouse bays, guide walls, and aprons would be removed. Once the powerhouse and spillway structures have been removed, the removal of the embankment dam would be completed. WSP price considers cofferdam and diversion for both scenarios and concrete stoplogs.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. The earth dams would be completely removed under the full

removal scenario. It is assumed excavated earth material will stay onsite to reflect the unit price prepared by M&H.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Cubic yard unit price was taken from the M&H estimate. As part of the earth dam removal, the concrete core wall will be demolished and disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel Dredging

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal, a 200-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal scenarios, this work includes additional hydraulic dredging of the reservoir area beyond the 200-foot-wide pilot channel during the drawdown process to restore the floodplain characteristics of the AuSable River. Unit quantities derived from M&H estimate and does not take into consideration additional volume removed for contaminated non-hazardous material. All material is considered non-contaminated and reused onsite. Following removal of the dam.

For the partial removal scenario, WSP considered an 85% quantity reduction in volume removed based on installation of a replacement weir system and upstream reservoir design to maintain a smaller impounded water level.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Excavation

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Reinforced Concrete Demo

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H cost estimate. The powerhouse structure would be left in place under the non-power operation option. Once the electrical generating equipment had been removed, water intake into the power plant would be plugged with concrete and the power conduits beneath the powerhouse would be filled with sand.

Remove or Lay-Up Equipment: Disable Generating Capacity

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the generating capacity with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Remove or Lay-Up Equipment: Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power

Channel Creation - Riffle Section at Downstream Tie In

WSP derived cost for performing additional channel restoration for a length immediately at and above the dam that includes imported rock. For the partial removal, an 860-foot-length is considered upstream of the revised water impounded area. For the full removal, a 1,140-foot-length is considered for the dam footprint extending to the same termination point as the partial removal.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot-drop and 3-foot-footer) and 4-foot-width.

Installation of Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 26-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 6-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Owner's Cost

An owner's cost of 15% of the construction subtotal was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $421,304 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal with an additional $400,000 for a concrete weir and fish ladder design, and $742,985 to move the substation were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal with an additional $742,985 to move the substation were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring and O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal were applied. These costs may be variable as the design develops and permit stipulations are identified.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.8 FOOTE DAM COST ESTIMATE ACTIVITIES

Table 4.6 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.6 Foote Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Remove Lines from Plant to Substation		X	X

Remove Lines from Plant to Substation

Price per linear foot was taken from the M&H estimate for removal lines from the plant to the substation. The partial and full removal options assume that the Foote Dam Plant would be demolished and therefore, electricity would no longer be required.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary.

Remove Septic Tank / Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 16 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove Turbines

Price per ton was taken from the M&H estimate. Under the partial and full removal options, turbines would be removed during decommissioning and transported to an off-site disposal area.

Remove Generators

Price per ton was taken from the M&H estimate. Under the partial and full removal options, generators would be removed during decommissioning and transported to an off-site disposal area.

Remove Cranes

Price per ton was taken from the M&H estimate. Under the partial and full removal options, cranes would be removed during decommissioning and transported to an off-site disposal area.

Remove Diesel Generator

Price per ton was taken from the M&H estimate. Under the partial and full removal options, the diesel generator would be removed during decommissioning and transported to an off-site disposal area.

Remove Fixtures

Price per ton was taken from the M&H estimate. Under the partial and full removal options, fixtures would be removed during decommissioning and transported to an off-site disposal area.

Remove Hoists

Price per ton was taken from the M&H estimate. Under the partial and full removal options, hoists would be removed during decommissioning and transported to an off-site disposal area.

Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, electrical equipment would be removed during decommissioning and transported to an off-site disposal area.

Reinforced Concrete/Masonry Demolition Including Spill Tubes, Intake/Tailrace, Retaining Wall & Aprons

Cubic yard unit price was taken from the M&H estimate. Per the M&H estimate, the scope of work for both the partial and full removal scenarios includes demolition of the roof, masonry superstructure, reinforced concrete substructure and foundation, substation, gates and valves, tailrace guide walls and aprons, and upstream and downstream sheet pile cutoffs. All the demolished material would be transported offsite for disposal in a designated landfill area.

Remove Trash Racks

Price per ton was taken from the M&H estimate. Under the partial and full removal options, trash racks would be removed during decommissioning and transported to an off-site disposal area.

Remove Valves

Price per ton was taken from the M&H estimate. Under the partial and full removal options, valves would be removed during decommissioning and transported to an off-site disposal area.

Remove Gates

Price per ton was taken from the M&H estimate. Under the partial and full removal options, gates would be removed during decommissioning and transported to an off-site disposal area.

Demolish And Remove Spillway Including Concrete Weir and Apron: Reinforced Concrete Demo

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate for this cost activity includes demolition and removal of the spillway structure, including gates, bridge, concrete weir, and apron. For the partial removal, the spillway guide walls, weir and apron would remain in place with gates removed. For the full removal, the demolition would be complete and include approach guide walls and apron, stilling basin weir, and tailrace guide walls and apron. The upstream sheet pile cutoff would also be removed to below the natural river channel level. All demolished material would be transported offsite for disposal in a designated landfill/recycled (salvage).

Remove Spillway Gates

Price per ton was taken from the M&H estimate. Under the partial and full removal options, spillway gates would be removed during decommissioning and transported to an off-site disposal area.

Remove Hoist Rails/Platform

Price per ton was taken from the M&H estimate. Under the partial and full removal options, spillway hoist rails/platform would be removed during decommissioning and transported to an off-site disposal area.

Drain 1,702-Acre Reservoir

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate includes draining the reservoir in a controlled manner through the powerhouse and spillway structure as they are demolished and removed in a staged process. The staged removal of the spillway would require that a steel sheet pile, gravel-filled cellular cofferdam with removable stoplogs, be placed upstream of the spillway. This cofferdam would allow the demolition of the entire spillway while regulating the diversion of river flows through the powerhouse structure. Once the reservoir has been lowered to the spillway foundation slab, the cofferdam would be removed to allow flows to be diverted through the previous spillway area to the natural river channel, and the remaining powerhouse bays, guide walls, and aprons would be removed. Once the powerhouse and spillway structures have been removed, the removal of the embankment dam would be completed. WSP price considers cofferdam and diversion for both scenarios and concrete stoplogs.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. The earth dams would be completely removed under the full removal scenario. It is assumed excavated earth material will stay onsite to reflect the unit price prepared by M&H.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Cubic yard unit price was taken from the M&H estimate. As part of the earth dam removal, the concrete core wall will be

demolished and disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall - Sheet Piling Removal

Square foot unit price was taken from the M&H estimate. This activity accounts for the sheet pile cutoff, in which all of the sheet pile wall as part of the core wall will be removed and disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel Dredging

Cubic yard unit price and quantity was taken from the M&H estimate. For both the partial and full removal, a 200-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal scenarios, this work includes additional hydraulic dredging of the reservoir area beyond the 200-foot-wide pilot channel during the drawdown process to restore the floodplain characteristics of the AuSable River. Unit quantities derived from M&H estimate and does not take into consideration additional volume removed for contaminated non-hazardous material. All material is considered non-contaminated and reused onsite. Following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Excavation

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Reinforced Concrete Demo

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Sheet Piling Removal

Square foot unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for sheet pile cutoff with all material disposed of offsite.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H cost estimate. The powerhouse structure would be left in place under the non-power operation option. Once the electrical generating equipment had been removed, water intake into the power plant would be plugged with concrete and the power conduits beneath the powerhouse would be filled with sand.

Remove or Lay-Up Equipment: Disable Generating Capacity

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the generating capacity with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's

electromechanical equipment.

Remove or Lay-Up Equipment: Remove Electrical Equipment

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the electrical equipment with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Salvage

Lump sum cost was taken from the M&H estimate for salvage pricing as detailed in the M&H estimate report. Due to its lower salvage value at the time of their estimate and the level of this cost estimate, pricing for updated market value in salvage rates was not evaluated/applied as it was expected to rebound, which would reduce overall costs considered.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Apply Erosion Control Measures - Silt Fence

Price per linear foot and unit quantity was taken from the M&H estimate. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 20% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the AuSable River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 80% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the AuSable River, as well as both banks for all tributary lengths.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Channel Creation - Riffle Section at Downstream Tie In

WSP derived cost for performing additional channel restoration for a length immediately at and above the dam that includes imported rock. For the partial removal, a 950-foot-length is considered upstream of the revised water impounded area. For the full removal, a 1,050-foot-length is considered for the dam footprint extending to the same termination point as the partial removal.

Fish Passage w/ Sea Lamprey Control

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 42-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 6-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot drop and 3-foot footer) and 4-foot width.

Installation of Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 26-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 6-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Construction Management and Biological Monitoring

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal were applied. These costs may be variable as the design develops and permit stipulations are identified.

Owner's Cost

An owner’s cost of 15% of the construction subtotal was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $433,781 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.9 COST ESTIMATE RESULTS SUMMARY

The full conceptual decommissioning cost estimate for each dam site and scenario are provided in Appendices A through F. Tables 4.7 to Table 4.12 provide a summary of total cost by category for Mio, Alcona, Loud, Five Channels, Cooke, and Foote dams, respectively.

Table 4.7 Mio Dam Cost Estimate Results Summary

DESCRIPTION	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	-	$142,000	$142,000
Decommissioning and Demolition	$286,719	$14,992,403	$19,978,887
Abatement and Regulated Material Removal	-	$13,642,734	$13,642,734
Salvage	-	$(42,763)	$(42,763)
Environmental and Restoration	$1,238,558	$27,759,776	$31,745,354
Subtotal	**$1,525,277**	**$56,494,150**	**$65,466,212**
Project Indirect	$1,100,270	$9,339,540	$10,778,812
Contingency Cost	$152,528	$5,649,415	$6,546,622
Total Project Cost	**$2,778,075**	**$71,483,105**	**$82,791,646**

Note: Variation between totals in the estimates shown in this report and the April 2024 Road Map are due to the following:

1. Rounding of quantities to the next whole integer were applied in the estimates herein.
2. Verifications of quantity by unit price to equate to WSP Opinion of Costs, rounded to the next whole dollar were applied in the estimates herein.

Table 4.8 Alcona Dam Cost Estimate Results Summary

DESCRIPTION	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	-	$142,000	$142,000
Decommissioning and Demolition	$253,867	$9,729,946	$15,297,551
Abatement and Regulated Material Removal	-	$20,763,373	$20,763,373
Salvage	-	$(36,499)	$(36,499)
Environmental and Restoration	$2,117,712	$25,921,951	$29,505,029
Subtotal	**$2,371,579**	**$56,520,771**	**$65,671,454**
Project Indirect	$1,398,871	$7,966,166	$9,442,054
Contingency Cost	$237,158	$5,652,078	$6,567,146
Total Project Cost	**$4,007,608**	**$70,139,015**	**$81,680,654**

Note: Variation between totals in the estimates shown in this report and the April 2024 Road Map are due to the following:

— Kiewit Infrastructure Company. 2021. Supplemental Hydroelectric Project Estimates.

APPENDIX

A MIO DAM HYDROELECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

A-1 MIO DAM SITE SUMMARY

Site Characteristics

- Two, 40-foot-high earth embankment dam sections, each with a concrete core wall.
- A 17-foot-high concrete spillway with one, 12.7-foot-high steel radial gate and a concrete-lined discharge channel extending approximately 220 feet downstream with a 6.5-foot-high concrete weir located approximately 45 feet downstream.
- A 530-foot-long auxiliary spillway located at the end of the south embankment dam.
- A reservoir with a normal surface area of 661 acres at elevation 962.6 feet (USGS datum) and a gross storage of 6,061 acre-feet.
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 3,885 kW. The powerhouse also contains two spill tubes used primarily as the service spillway. Only one spill tube is operational at this time.
- A 185-foot-long concrete tailrace with retaining walls.
- Associated appurtenant structures.

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- Known areas of groundwater contamination (PFAS) upstream of Mio and Upstream Air Force base is a Superfund site.
- USFS is a significant property owner adjacent to the Project with public amenities. USFS has mandatory conditioning authority under the Federal Power Act (4(e) measures) which FERC must accept as part of their license Order which makes USFS important stakeholder during relicensing.
- Historic Properties Management Plan (HPMP) – Historic Operators Homesite
- Water Quality out of compliance; MDNR Management Plan calls for removal of the dam. Upwelling system in place without success.
- Wild & Scenic River downstream to Alcona – popular paddling/float trip water trail (Blue water trail recreation)
- Recreation is important resource to region (fishing, paddling, campgrounds, etc.)
    - Camp 10 Boat Launch, Canoe portage at dam, Joseph Pillars Park, MDNR Mio Dam State Forest Campground, MDNR Mio Pond Access, Tailwater access, Scenic Overlook, Oscoda County Park, Rainbow Resort, Wayside Recreation Site, U.S. Forest Service.
- MNDNR lists Mio as priority for removal (only one on Au Sable) due to warming in the reservoir and its detriment to the cold-water fishery (and wild and scenic river designation to Alcona).

Future License Conditions

- Operations monitoring/automation
- Water Quality mitigation/monitoring
- Recreation enhancements
- RTE Species Management Plans
- Fish stocking/funding
- Fish Passage
- Land/Shoreline Management
- HPMP
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Formalization to run of river mode
- Fish passage requirements
- Temperature and dissolved oxygen (DO) exceedances
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Mio Hydroelectric Dam 2021 Powerhouse Condition Assessment Results," the powerhouse was given a rating of 'Green', indicating that no major repairs will be needed for another 10 to 20 years. It was recommended that steel support columns in the powerhouse are cleaned and recoated. It was also recommended cracks observed throughout the exterior and interior of the powerhouse are monitored on a regular basis.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder between May and June 2018 and consisted of the concrete features/structures (Auxiliary Spillway, Downstream Left Embankment Retaining Wall- Segment 1, Downstream Left Embankment Retaining Wall- Segment 2, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Log Chute, Spillway Abutment, Spillway Gate Piers and Concrete, Spillway/Powerhouse Apron, Spillway Structural Walkway Deck, Training Wall, Tumble Bay and Spillway, Upstream Apron, Upstream Left Wing Wall, Upstream Powerhouse Piers, Upstream Right Wing Wall) and spillway structural walkway. The findings are summarized in a report dated January 4, 2019. Based on this report, the training wall was rated as 'YELLOW' (3 to 5 years before major repairs or replacement is necessary). Three site features were rated as 'BLUE' (5 to 10 years before major repairs or replacement is necessary): segment 2 of the left embankment retaining wall, the downstream powerhouse piers, and the log chute. In addition, cleaning of the cracks and sealing the leaks at the base of the downstream slope of the auxiliary spillway was recommended. Golder recommended that the cause and extent of the horizontal cracks at the base of the powerhouse spanning the downstream powerhouse piers be investigated further to develop appropriate repairs, as well as monitoring of the joint between the left wing-wall and pier to confirm that no movement is taking place. Golder also recommended that further study be completed to assess whether the seepage noted during the dive inspection is leading to piping of the soils below and around the dam and the extent to which pore water pressures are generating uplift forces that pose a risk to the dam. Other structures that were assessed in this report were generally found to be in good condition and given a 'GREEN' rating.

An Auxiliary Spillway Assessment Report prepared by BARR (dated November 2017) includes the observations of a non-destructive visual inspection and summarizes the review of design data for the auxiliary spillway. The report also includes the results of the Potential Failure Modes Analysis (PFMA) focused on the auxiliary spillway. The auxiliary spillway was observed to be in good condition. There were localized areas of missing joint sealant and random tight cracking in the stilling basin apron slab and sloped baffle wall section slab. The ongoing inspections should continue to look for cracking, spalling, leakage, joint offsets, and missing joint sealant. The data review included review of the original design computations, soil boring logs in the area of the auxiliary spillway, related FERC correspondence, and construction drawings. The design was found adequate for the design assumptions used at the time of the original 1988 design. The 1988 design and 2009 repairs also appear adequate for the auxiliary spillway to safely pass the current Probable Maximum Flood (PMF) which is less than the PMF at the time of the original auxiliary spillway and repair design. As a result of the focused PFMA, no new monitoring methods or significant risk reduction measures were identified. The focused PFMA highlighted the following maintenance, surveillance, and risk reduction measures related to the auxiliary spillway.

DIVE INSPECTIONS

- June 22, 2021, Spillway Leak Inspection
    - An upstream dive inspection was conducted to assist CEC in identifying the source of the heavy flow through the tumble bay weep holes. Only a slight dye color was detected downstream during the dive inspection which occurred when placing the dye at the upstream end of the left cofferdam concrete seal.
- June 13 and 14, 2018 Part 12 Inspection
    - Upstream
        - Left wing wall and Unit 1 left pier wall exhibited spalling and up to 6 inches of separation between the two walls.
        - Cracking was found on the right powerhouse Unit 1 wall.
        - No significant findings were noted on the powerhouse Unit 2 walls, the right abutment wall, and log chute walls.
        - Right wing wall exhibited spalling, voids in the concrete, exposed rebar, and separation at the interface with the core wall.
        - Spalling and cracking exhibited on the concrete wall spanning between the right abutment wall and the Unit 2 pier wall.
    - Downstream
        - Right embankment retaining wall/spillway abutment wall exhibited spalling and a deteriorated joint at the interface with the weir which had cold water flowing through it.
        - Spalling was noted in the tumble bay.
        - Concrete damage in the freeze/thaw zone was noted on the weir. Exposed rebar and spalling were also exhibited at the weir/downstream apron interface.
        - Spillway apron exhibited spalling and broken concrete.
        - Training wall exhibited spalling with exposed wire mesh.
        - Left embankment retaining wall exhibited spalling and cracking with cold water flowing through.
        - No significant findings were noted on the Units 1 and 2 draft tubes and walls, with the exception of a hole in the concrete in the Unit 1 draft tube.
        - Tailrace apron exhibited spalling and open joints with cold water flowing through.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a “performance-focused” inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a “deep dive”

into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

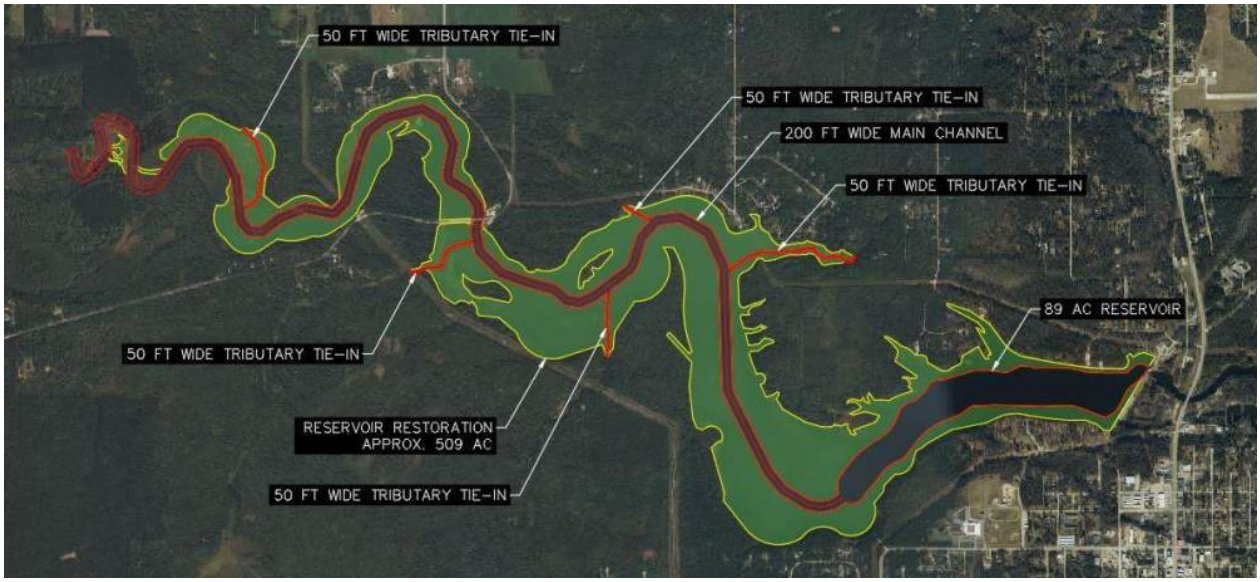
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement.

Current Remediation Projects in LTFP

- Unit 1 Wicket Gate Refurbishment – Capital
- Unit 2 Wicket Gate Refurbishment – Capital
- Electrical Safety Project – Capital
- Training Wall Replacement – Capital

Remediation Projects not in LTFP

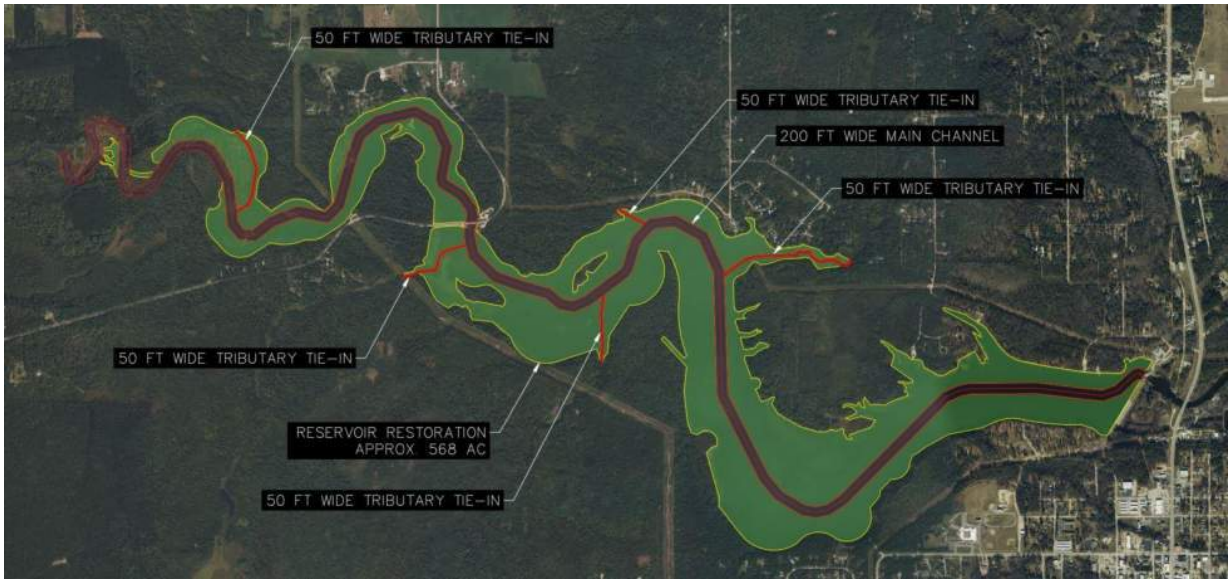


- Tumble Bay Leakage Through Concrete Beneath Spill Gates
- Powerhouse Armpit Leaks
- SF6 Breaker Maintenance
- Concrete Apron Joint Sealing Redo

Generation

The Mio development consists of 2 units with a calculated maximum generation capacity of 43,450 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 15,423 MWH, contributing 3% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 22,690 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
- Cons/Risks
  - Auxiliary spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Water quality (temperature and DO) may still be out of compliance for cold water fisheries under License Article 405.
  - May also still cause sediment transport issues. Mio Dam should be removed before all other downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Camp 10 Road Bridge partially blocking flow and causing upstream sedimentation may need to be replaced or have a widened underpass.

- Potential for contaminated sediment removal and disposal due to the upstream PFAS groundwater contamination from the Camp Grayling Superfund site. Sediment characterization required to determine distribution of potential contamination. Requires coordination with EPA to determine responsibility of cost burden.
- Public disapproval of this option due to its socioeconomic and recreational impact.
    - The Mio Dam also received a State Historic Marker in 2005, which may create additional resistance to the dam removal.
- Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir extents.
- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
    - No inhabited residential properties along riverbanks immediately downstream of dam
    - Pedestrian fishing pier approximately 550 FT downstream of dam along left bank
    - RT 33/Morenci Ave Bridge approximately 800 FT downstream of dam
    - Mio Au Sable River Launch approximately 1,350 FT downstream of dam along right bank (start of Wolf Creek pedestrian Trail along right bank)
    - Fed Trail 4367 Canoe Landing along left bank approximately 9,100 FT downstream of dam (start of Fed Trail along left bank).

Decommissioning (Full)

- Pros
    - Eliminates legal liability and maintenance of existing facilities.
    - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
    - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
    - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
        - Habitat can be restored along the entire footprint of the dam.
    - Eliminates issues of water quality (temperature and DO).
    - Eliminates sediment transport issues (if flow passage through Camp 10 Road Bridge is improved).
- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Mio Dam should be removed before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Potential for contaminated sediment removal and disposal due to the upstream PFAS groundwater contamination from the Camp Grayling Superfund site. Depending on the distribution of such contamination within the reservoir, this may be a significant cost burden.
    - Camp 10 Road Bridge/Boat Launch rebuild or under passage widening may add significant additional cost burden.

A-2 MIO DAM NO-POWER GENERATION SCENARIO CONCEPTUAL ESTIMATE

Consumers Energy
Mio Dam
Decommissioning Cost Evaluation - Non-Power Removal

Category	Cost Activity	Unit	WSP Unit Cost	Quantity	WSP Opinion of Cost
Decommissioning and Demolition	Leave Powerhouse Intact	LS	$198,161.00	1	$ 198,161.00

	Concrete Weir Installation	LF	$ 5,050.00	200	$ 1,010,000
	Installation of Fish Passage	VLF	$ 50,000.00	9	$ 450,000
	Subtotal				**$ 56,494,150**
Project Indirect	Owner's Cost				$ 6,541,126
	Engineering and Permitting				$ 1,926,263
	Construction Management & Biological Monitoring				$ 872,151
Contingency	Contingency				$ 5,649,415
Total Project Costs					**$ 71,483,105**

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database.

4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

Total Project Costs					**$ 82,791,646**

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database.

APPENDIX

B ALCONA DAM HYDROELECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

B-1 ALCONA DAM SITE SUMMARY

Site Characteristics

- Two, 60-feet-high earth embankment dam sections, each with a concrete core wall
- A 250-feet-long emergency spillway located at the end of the east embankment
- A reservoir with a normal surface area of 1,006 acres at elevation 829.0 feet (USGS datum) and a gross storage of 12,547 acre-feet
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 7,905 kW
- A 135-foot-long concrete tailrace with retaining walls
- Associated appurtenant structures
- Recreation Facilities consist of Alcona Park, East & West Tailwater and canoe portage, and USFS Hwy 4001 Canoe Landing

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- No residential development around reservoir so the number of private landowner/stakeholders in licensing will be less than other sites
- USFS is a significant property owner adjacent to the Project with public amenities. USFS has mandatory conditioning authority under the Federal Power Act (4() measures) which FERC must accept as part of their license Order which makes USFS important stakeholder during relicensing.
- Recreation is important resource to region (Popular with canoe trips, camping, county park)
- Water quality out of compliance; MDNR Management Plan calls for removal of the dam
- Significant wild rice population (Tribal interest)
- Historic Properties Management Plan (HPMP) – three original operator structures

Future License Conditions

- Operations monitoring/automation
- Water Quality mitigation/monitoring
- Recreation enhancements
- RTE Species Management Plans
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- HPMP
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Fish passage requirements or mitigations
- Temperature and potentially dissolved oxygen (DO) exceedances or mitigations will be required
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements
- Ongoing maintenance of ageing equipment

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled “Alcona Hydroelectric Dam 2021 Powerhouse Condition Assessment Results,” the powerhouse was given a rating of 'Green',

indicating that no major repairs will be needed for another 10 to 20 years. Although no immediate major repairs are required, it was recommended that several features of the structures are monitored on a regular basis.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder Associates Inc. (Golder) on September 27 and 28, 2018 and consisted of the above-water concrete features/structures consisting of Downstream Powerhouse Pier, Abutments, and Walkway, Intake Deck Upstream Support Wall, Left Embankment Retaining Wall, Right Embankment Retaining Wall, Upper Left Embankment Retaining Wall, Upstream Powerhouse Piers. The findings are summarized in a report dated May 14, 2019. Based on this report, the intake deck upstream support wall was rated as 'BLUE' (5 to 10 years before major repairs or replacement is necessary). The other structures that were inspected during this condition assessment were rated 'GREEN'. The concrete feature ratings were based on above-water observations only. It was recommended to perform an underwater investigation of each feature and to adjust the ratings and remaining life estimates accordingly.

DIVE INSPECTIONS

- October 6, 2022, Unit #2 draft tube/east tailrace/downstream water boils Inspection
    - Bottom of upstream and downstream east retaining walls separated 30 inches – separation filled with stone/concrete blocks with water coming through.
    - Boils observed within 2 vertical construction joints along east retaining wall – 2 boils within each joint.
    - 2 concrete spalls observed in draft tube ceiling.
    - 3 concrete spalls along east apron slab with rebar visible.
    - 3 cracked out pieces of concrete observed along east apron with rebar visible.
    - Concrete spall observed on baffle wall weir.
    - East apron slab separated from baffle wall at several locations. Construction joint in east baffle wall is misaligned by 8 inches between east and west portions.
    - Apron slab downstreams of baffle wall spalled with rebar exposed.
    - 4 water boils are present downstream of the apron slabs.
- October 5, 2022, Unit #1 draft tube/west tailrace
    - 2 concrete spalls observed in draft tube bay for unit #1.
    - Separation of 3 vertical construction joints along west retaining wall with water boils.
    - 4 concrete spalls observed along west retaining wall.
    - 7 diagonal cracks observed along west retaining wall, with several water boils in cracks.
    - 6 concrete spalls observed along west concrete apron slabs .
    - Several apron slab horizontal joints are misaligned/offset, including joint between apron slabs and baffle wall.
    - 8 cracks present along west apron slab.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

CURRENT PART 12 RECOMMENDATIONS:

Due the on-going RIDM process for this project, FERC did not require a formal Part 12 IC inspection and report for 2021. However, an Informal Part 12 inspection was performed. The informal report was limited to a field inspection and a general review of the project data. Recommendations in the informal report cover only site condition issues and are relatively minor. The report did review recommendations from the previous Part 12 report. There is an outstanding recommendation that the existing stability analyses for the embankment and structures should be updated utilizing the current PMF. If this work has not been completed and there is no confirmation that the assets meet current required safety factors, it could lead to recommendations for remediation/upgrades to the project.

Current Remediation Projects in LTFP

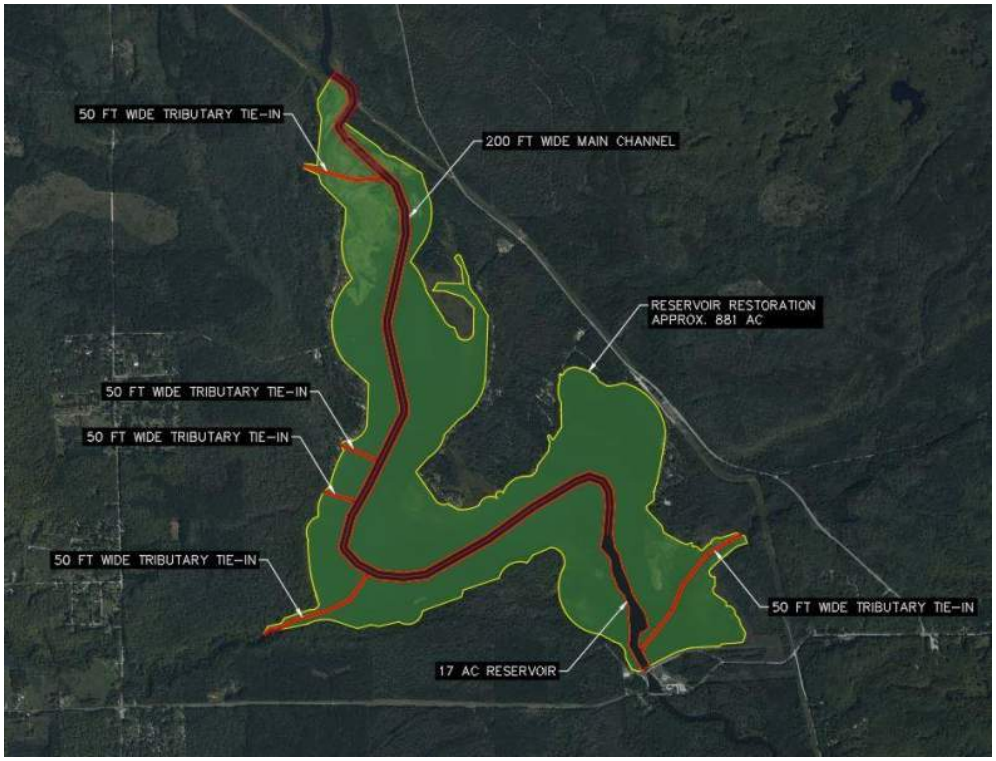
- Powerhouse Window Replacement - Capital
- Core Wall Remediation - Capital
- Intake Deck Upstream Support Wall - Capital
- Risk Informed Decision Making - Capital
- Trash Rack Ergonomics - Capital
- Electrical Safety Project - Capital
- Unit 1 Bearings & TGB Sleeve & Wicket Gates - Capital
- Relief Well Installation - Capital
- Units 1 & 2 Governor Replacement - Capital
- Artesian Design Study - Capital
- Units 1 & 2 Head Gate Replacement - Capital
- Left Driveway Retaining Wall Repairs - O&M
- Unit 1 Concrete Repairs (In Spiral Case) - O&M

Remediation Projects not in LTFP

- Head Gate Hoists – Capital

- Unit 2 Bearings & TGB Sleeve & Wicket Gates - Capital
- Unit 2 Overhaul (double acting Kaplan units)

FERC Required Spillway Projects (in LTFP)

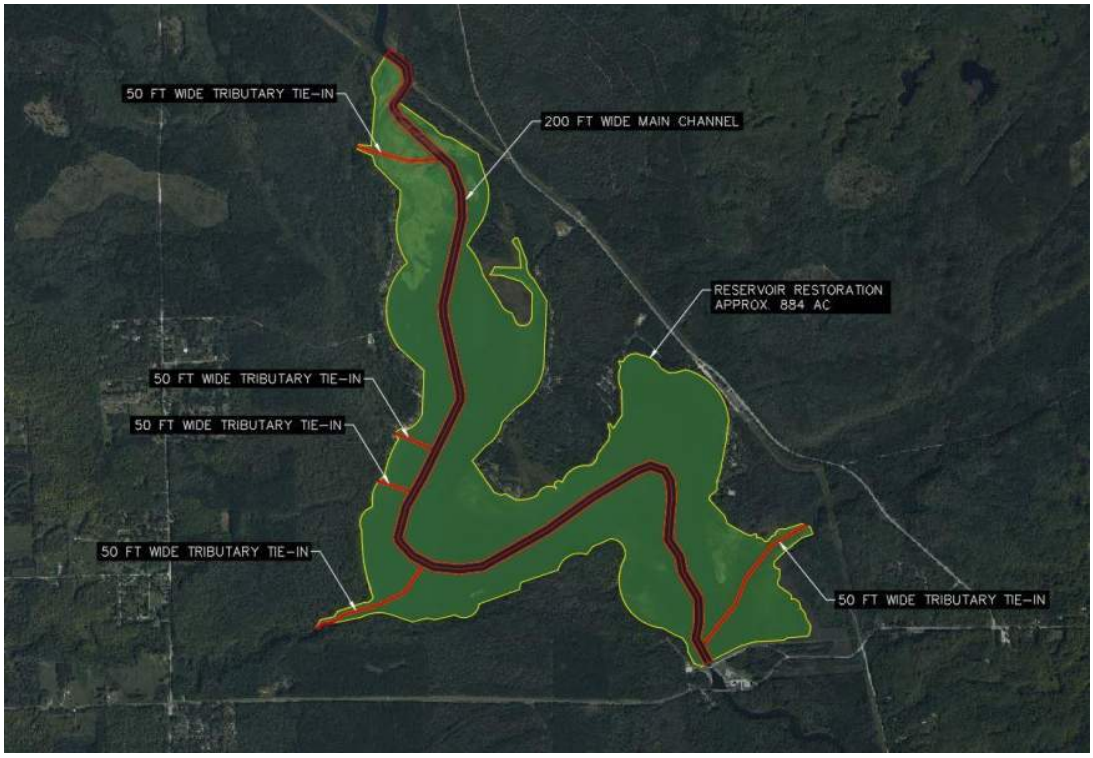


- RIDM Resolution (Auxiliary Spillway/Embankment Modifications/etc.) -Capital
    - The Alcona Risk Informed Decision Making Project identified the risk for auxiliary spillway erosion and subsequent failure exceeded the FERC tolerable risk guidelines. CEC plans to safely convey discharge from the auxiliary spillway across Bamfield Road and toward the forested area to the south by:
        - Installing scour protection along parts of the left non-core wall embankment upstream slope
        - Regrading about 360 feet of the left non-core wall embankment into a cone-shaped transition
        - Constructing a flow-guiding berm to Bamfield Road
        - Re-grading the auxiliary spillway channel to direct water toward the centerline of the spillway
        - Regrading Bamfield Road and constructing a scour-resistant cross to direct discharge across the road toward the Au Sable River

Generation

The Alcona development consists of 2 units with a calculated maximum generation capacity of 70,080 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 29,025 MWH, contributing 6% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 56,599 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.

- Cons/Risks
    - Emergency spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Water quality (temperature and potential DO) may still be out of compliance for cold water fisheries under License Article 405.
    - May also still cause sediment transport issues. Alcona Dam should be removed after the removal of the Mio Dam and before all other downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Potential for contaminated sediment removal and disposal due to the upstream PFAS groundwater contamination from the Camp Grayling Superfund site. Sediment characterization required to determine distribution of potential contamination. Requires coordination with EPA to determine responsibility of cost burden.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir limits.
    - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a SIGNIFICANT HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
        - 3 inhabited residential properties are located along right bank between 500 FT to 800 FT downstream of dam (along S Alcona Dam Road)
        - Bamfield Road Bridge is located approximately 500 FT downstream of dam
        - Bobcat Creek Park is located approximately 10,000 FT downstream of dam

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
  - Habitat can be restored along the entire footprint of the dam.
  - Eliminates issues of water quality (temperature and potential DO).
  - Eliminates sediment transport issues.

- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Alcona Dam should be removed after the removal of the Mio Dam and before all other downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Potential for contaminated sediment removal and disposal due to the upstream PFAS groundwater contamination from the Camp Grayling Superfund site. Depending on the distribution of such contamination within the reservoir, this may be a significant cost burden.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Significant planning and analysis required to determine how to manage existing recreational features.

License Surrendering (Non-Power Operation)

- Pros
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage improved, but requires installation of fish passage system; discontinuation of MDNR stocking.

- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
    - The non-power operation of the Alcona Dam may cost more than either of the removal options due to repairs that are needed for the earth dam and core wall, the tailrace, upslope protection, and a possible extension needed for the right embankment according to the Kiewit cost evaluation. The Kiewit cost evaluation also considers a widening of the auxiliary spillway which includes a flow guiding berm and regrading of Bamfield Road.
    - Water quality (temperature and potential DO) may still be out of compliance for cold water fisheries under License Article 405. Significant costs may be required bring the water temperature into compliance to support cold water fisheries.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database.

APPENDIX

C LOUD DAM HYDROLECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

C-1 LOUD DAM SITE SUMMARY

Site Characteristics

- Two, 42-foot-high earth embankment dam sections, each with a concrete core wall.
- A 20-foot-high concrete spillway with three, 15.5-foot-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with a 6.5-feet-high concrete weir located approximately 45 feet downstream.
- A 100-feet-long emergency spillway.
- A reservoir with a normal surface area of 743 acres at elevation 742.6 feet (USGS datum) and a gross storage of 6,987 acre-feet.
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 4,000 kW.
- A 35-foot-long concrete apron in the tailrace with concrete retaining walls extending approximately 125 feet downstream.
- Associated appurtenant structures.
- Peaking plant operations (only on Au Sable)
- Significant amount of surrounding lands owned by USFS and Consumers; no development.
- Operationally linked with Five Channels Dam

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- Peaking plant reregulated by Five Channels Dam downstream
- USFS is a significant property owner adjacent to the Project with public amenities. USFS has mandatory conditioning authority under the Federal Power Act (4(e) measures) which FERC must accept as part of their license Order which makes USFS important stakeholder during relicensing. Sedimentation of upper end of reservoir
- Operators homes listed on National Register of Historic Places (NRHP)
- Considerable Public Recreation use on Au Sable River
- Majority public lands (USFS) and limited private property adjacent to shoreline
- Westgate, which is a popular overlook on M-65. The Iron Belle Trail/Iosco Exploration Trail will be using CE property near Westgate

Future License Conditions

- Operations monitoring/automation
- Recreation enhancements
- RTE Species Wildlife Management Plans
- Sediment Management
- Consult with USFS
- Land Management plan for buffer lands
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- Historic Properties Management Plan (HPMP)
- Retirement study
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Loss of peaking operations
- Fish passage requirements
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Loud Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo," The interior and exterior of the powerhouse structure was given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. Although no immediate major repairs are required, additional maintenance and monitoring will be required in several areas to prevent the need for future repairs. Additionally, it is recommended to repair the spalling with exposed rusting reinforcing steel above Unit 1 to prevent further deterioration.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder between June and July 2018 and consisted of the concrete features/structures (excluding the powerhouse) and spillway structural walkway. The findings were summarized in a condition assessment report for Loud Hydroelectric Dam dated January 4, 2019.

The key findings from the Loud Dam condition assessment identified two site features (embankment core wall section - above water, and training wall) that were rated as ORANGE (1 to 3 years before major repairs or replacement is necessary). One site feature (segment 2 of the downstream left embankment retaining wall) was rated as YELLOW (3 to 5 years before major repairs or replacement is necessary). In addition, periodic maintenance including cleaning and re-sealing of the joints is recommended for segment 1 of the downstream left embankment wall, log chute, and upstream spillway piers as soon as practicable. Golder recommends removing the vegetation overgrowth on the emergency spillway concrete sloping wall so that the remainder of the wall can be properly inspected. Golder also recommended refinishing the areas with protective coating loss on the spillway structural walkway to ensure corrosion does not reduce the design life of the structure. The underwater inspection of the right wing wall observed a 0.5-inch separation of the joint between the abutment and wing wall. Continued monitoring of the wing wall to abutment joint during routine dive inspections is recommended to confirm there is not future movement of the wall. Other structures that were inspected during this condition assessment and are included in this report were given a Green rating (10 to 20 years before major repairs or replacement is necessary).

DIVE INSPECTIONS

- Downstream Spillway, May 18, 2021:
    - 3 Diagonal cracks, 2 horizontal cracks, 2 vertical cracks, 4 concrete spalls, and 2 open vertical construction joints at north retaining wall.
    - 2 vertical cracks, 1 horizontal crack, 2 diagonal cracks, and 2 open vertical construction joints at divider pier between the spillway and powerhouse.
    - The downstream scour apron was separated from the divider wall at several locations by up to 8 inches. Several concrete spalls up to 5 inches deep were observed in the apron.
- Upstream Powerhouse & Spillway, May 19, 2021:
    - Lifting chains and connectors in the upstream spillway were deteriorated by up to 10%.
    - One horizontal crack was observed at the north retaining wall along the upstream spillway. One concrete spall was observed at the construction joint between the wing wall and the North retaining wall.

- Trash rack bars are deteriorated up to 10% throughout. Trash racks in Bay #3 are completely blocked with Zebra mussels. Bay 3 is a dead bay with not generating unit installed.
- One concrete spall at the pier between Bay #s 2 and 3.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement. The exception to this is the potential for repair of the core wall based on the results of the evaluation of survey data for ongoing movements, the repair of the left spillway retaining wall and the review of whether the emergency spillway is needed to pass the PMF.

Current Remediation Projects in LTFP

- Units 1 and 2 Governor Replacement – Capital
- Remote Spillgate Controls Installation – Capital
- Spillway Hoist Replacement – Capital
- Unit 1 Wicket Gate Replacement – Capital
- Unit 2 Wicket Gate Replacement – Capital
- Left Embankment Seepage Cutoff – Capital
- Electrical Safety Project – Capital
- Transformer Replacement – Capital
- Left Embankment Retaining Wall Replacement – Capital
- Unit 1 Generator Rewind – Capital
- Powerhouse Window Replacement – Capital
- Intake Deck Remediation – O&M

Remediation Projects not in LTFP

- Grass Lined Emergency Spillway Modification
- Units 1, 2, and 3 Headgate Replacement or Remediation
- Units 1 and 2 Concrete Repairs

Generation

The Loud development consists of 2 units with a calculated maximum generation capacity of 35,040 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 18,689 MWH, contributing 4% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 23,588 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)

Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - It is unlikely that the Loud Dam will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.

- Cons/Risks
  - Emergency spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - May also still cause sediment transport issues. The Loud Dam should be removed after removal of all upstream dams and before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
  - Public disapproval of this option due to its socioeconomic and recreational impact.
  - Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir extents.
  - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a SIGNIFICANT HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
    - 3 residential homes along right bank approximately 1,100 FT to 1,500 FT downstream of dam

Decommissioning (Full)

- Pros
    - Eliminates legal liability and maintenance of existing facilities.
    - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
    - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
    - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
    - Habitat can be restored along the entire footprint of the dam.
    - Eliminates sediment transport issues
    - It is unlikely that the Loud Dam impoundment will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Loud Dam should be removed after all upstream dams and before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Significant planning and analysis required to determine

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
        - Future repairs to dam structure.
    - Fish passage installation required.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

Environmental and Restoration	Seed former reservoir bottom	AC	$ 3,100.00	583	$ 1,807,300
	Plant former reservoir bottom	AC	$ 3,072.00	583	$ 1,790,976
	Apply Erosion Control Measures: Silt Fence	LF	$ 5.00	16,000	$ 80,000
	Apply Erosion Control Measures: Rip Rap Protection	CY	$ 150.00	5,000	$ 750,000
	Bank Stabilization: Hard Structure	LF	$ 333.33	12,078	$ 4,025,960
	Bank Stabilization: Live stakes and Jute Matting	LF	$ 54.33	48,312	$ 2,624,791
	Reuse (grading) of non-contaminated excavated and dredged material	CY	$ 8.00	846,970	$ 6,775,760
	Grading & Surface Preparation/Amendments	AC	$ 6,700.00	583	$ 3,906,100
	Channel creation: Riffle section at downstream tie in	CY	$ 150.00	10,074	$ 1,511,112
	Subtotal				**$ 36,072,841**
Project Indirect	Owner's Cost				$ 5,410,927
	Engineering and Permitting				$ 1,262,550
	Construction Management & Biological Monitoring				$ 721,457
Contingency	Contingency				$ 3,607,285
Total					**$47,075,060**

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database.

APPENDIX

D FIVE CHANNELS DAM HYDROELECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

D-1 FIVE CHANNELS DAM SITE SUMMARY

Site Characteristics

- Two, 45-feet-high earth embankment dam sections, each with a concrete core wall
- A 25-foot-high concrete spillway with three, 14.5-foot-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with an 8-foot-high concrete weir located approximately 60 feet downstream
- A reservoir with a normal surface area of 212 acres at elevation 715.0 feet (USGS datum) and a gross storage of 3,419 acre-feet
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 5,966 kW
- A 35-foot-long concrete apron in the tailrace with concrete retaining walls extending approximately 120 feet downstream
- Associated appurtenant structures
- Peaking operations

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- Peaking operations
- USFS is a significant property owner adjacent to the Project with public amenities. USFS has mandatory conditioning authority under the Federal Power Act (4() measures) which FERC must accept as part of their license Order which makes USFS important stakeholder during relicensing
- Considerable Public Recreation use on Au Sable River
- Majority public lands (USFS) and limited private property adjacent to shoreline
- Most visible dam on the Au Sable River due to the bridge crossing for M-65 at the dam. The old M-65 bridge is owned by MDOT and is key bridge for snowmobilers to cross the river.
- Five Channels Dam "Workers Camp" is listed on National Register of Historic Places

Future License Conditions

- Operations monitoring/automation
- Water quality monitoring
- Recreation enhancements
- RTE Species Wildlife Management Plans
- Sediment Management
- Consult with USFS
- Land Management plan for buffer lands
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Historic Properties Management Plan
- Retirement study
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Loss of peaking operations
- Fish passage requirements
- Temperature and dissolved oxygen (DO) exceedances
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Five Channels Hydroelectric Dam 2021 Powerhouse Condition Assessment Results," the powerhouse was given a rating of 'Green', indicating that no major repairs will be needed for another 10 to 20 years. It was recommended that exposed reinforcing steel observed near one of the units be repaired to prevent further deterioration. It was also recommended that cracking and spalling observed throughout the exterior and interior of the powerhouse are monitored on a regular basis.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder between June and August 2018 and consisted of the concrete features/structures (Downstream Left Embankment Retaining Wall, Downstream Powerhouse Apron, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Log Chute, Spillway Abutment, Downstream Spillway Apron, Spillway Structural Walkway Deck, Training Wall, Tumble Bay and Spillway, Upstream Left Wing Wall, Upstream Powerhouse Piers, Upstream Right Wing Wall, Upstream Spillway Piers) and Spillway Structural Walkway. The training wall was rated as 'YELLOW' (3 to 5 years before major repairs or replacement is necessary). Another site feature, the log chute, was rated as 'BLUE' (5 to 10 years before major repairs or replacement is necessary). In addition, biennial dive inspections of the downstream powerhouse apron and right wing-wall are recommended for continued monitoring. Golder recommended refinishing of areas with loss of protective coating on the spillway structural walkway deck to ensure corrosion does not reduce the design life of the structure. It is also recommended to perform periodic maintenance including cleaning and sealing of the joints as soon as practicable. Other structures that were inspected during this condition assessment and are included in this report were generally found to be in good condition and given a 'GREEN' rating.

DIVE INSPECTIONS

- Upstream Spillway and Powerhouse, July 14, 2021:
    - Spall on concrete on right side of divider pier between spillway and powerhouse.
    - Spill bays 1 through 3 exhibited no defects however the cotter keys need replacing.
    - Open construction joint (up to 3 inches wide) with sediment coming through at the bottom at the intersection between right wing wall and retaining wall.
    - Upstream left wing wall and Bays 1 through 3 trash racks exhibited no defects.
    - Upstream left retaining wall exhibited vertical cracks, 2 concrete spalls, and a vertical open construction joint between the retaining wall and the wing wall.
    - Spall on right side of divider pier between powerhouse and spillway.
- Downstream Powerhouse and Spillway, July 15 and 19, 2021:
    - Spall on concrete on left tailrace retaining wall.
    - No defects exhibited in draft tube Bays 1 and 2 but a horizontal concrete spall was exhibited on the left side of the divider pier between Bays 2 and 3.
    - No defects exhibited in the log chute.

- An open construction joint was exhibited on the downstream divider pier between the powerhouse and spillway.
- Minor undermining of the powerhouse concrete apron slab was exhibited downstream of draft tube 2 however no concrete defects were noted.
- No defects were exhibited on the spillway downstream right retaining wall and weir wall.
- Cracks, spalls, and an open vertical construction joint were exhibited on the right side of the divider pier between the spillway and powerhouse.
- No significant defects were exhibited downstream of the spillway concrete scour apron however 1 spall was exhibited adjacent to a construction joint.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement.

Current Remediation Projects in LTFP

- Remote Spillgate Controls Installation – Capital
- Unit 1 Wicket Gate Refurbishment – Capital
- Unit 2 Wicket Gate Refurbishment – Capital
- Dead Bay and Log Chute Replacement – Capital
- Headgate Replacement – Capital
- Spillway Hoist Replacement – Capital
- Training Wall Replacement – Capital
- Trash Rack Ergonomics Project - Capital
- Intake Deck Concrete Repairs – O&M
- Left Embankment Stability Study – O&M

Remediation Projects not in LTFP

- Study of Water Left of Powerhouse in Groin Area
- Study of Wall Left of Powerhouse
- Unit Upgrades
- Backside Upstream Side of Powerhouse Leaking (might be addressed with Dead Bay Project)
- Units 1 and 2 Concrete Repairs

Generation

The Five Channels development consists of 2 units with a calculated maximum generation capacity of 52,560 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 25,032 MWH, contributing 6% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 32,728 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)

Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - It is unlikely that the Five Channels Dam will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
  - It is anticipated that less dredging will be required within this reservoir due to it being located directly downstream of the Loud Dam where a large portion of upstream sediments have already settled out. The existing 212-acre reservoir more closely mimics a wide river than a true reservoir. Limited bathymetry is available but based on aerials it looks to preserve the natural channel within the reservoir.
  - Less intense planning and analysis required to determine how to manage existing recreational features since reservoir shoreline should not significantly recede. There are also very few recreational features along this reservoir shoreline.

- Cons/Risks
  - Features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - May also still cause sediment transport issues. The Five Channels Dam should be removed after removal of all upstream dams and before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
  - Public disapproval of this option due to its socioeconomic and recreational impact.
  - Additional costs will be required to remove office buildings and warehouses adjacent to the dam. Contaminant surveys should be conducted for these buildings.
  - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to agriculture, uninhabited buildings, structures, or township or county roads, where environmental degradation would be minimal, and where danger to individuals is slight or nonexistent.

Decommissioning (Full)

- Pros
    - Eliminates legal liability and maintenance of existing facilities.
    - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
    - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
    - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
        - Habitat can be restored along the entire footprint of the dam.
    - Eliminates sediment transport issues
    - It is unlikely that the Five Channels Dam impoundment will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
    - It is anticipated that less dredging will be required within this reservoir due to it being located directly downstream of the Loud Dam where a large portion of upstream sediments have already settled out. The existing 212-acre reservoir more closely mimics a wide river than a true reservoir. Limited bathymetry is available but based on aerials it looks to preserve the natural channel within the reservoir.
    - Less intense planning and analysis required to determine how to manage existing recreational features since reservoir shoreline should not significantly recede. There are also very few recreational features along this reservoir shoreline.
- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Five Channels Dam should be removed after all upstream dams and before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Additional costs will be required to remove office buildings and warehouses adjacent to the dam. Contaminant surveys should be conducted for these buildings.

License Surrendering (Non-Power Operation)

- Pros
  - Lower initial cost burden
  - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
  - Fish passage improved, but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Office buildings and warehouses adjacent to dam can remain in place.
- Cons/Risks
  - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
    - Future repairs to dam structure.
  - Fish passage installation required.
  - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

D-2 FIVE CHANNELS DAM NO-POWER GENERATION SCENARIO CONCEPTUAL ESTIMATE

Consumers Energy
Five Channels Dam
Decommissioning Cost Evaluation - Non Power Operation

Category	Cost Activity	Unit	WSP Unit Cost	Quantity	WSP Opinion of Cost

Contingency	Contingency				$ 3,033,503
Total					**$ 39,587,216**

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database.

APPENDIX

E COOKE DAM HYDROLECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

E-1 COOKE DAM SITE SUMMARY

Site Characteristics

- Two, 50-feet-high earth embankment dam sections, each with a concrete core wall.
- A 25-foot-high concrete spillway with three, 15-foot-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with an 11.5-foot-high concrete weir located approximately 50 feet downstream.
- A reservoir with a normal surface area of 1,627 acres at elevation 678.5 feet (USGS datum) and a gross storage of 26,749 acre-feet.
- A concrete and masonry powerhouse containing three generating units with a total installed capacity of 7,500 kW.
- An approximately 120-foot-long concrete tailrace with retaining walls.
- Associated appurtenant structures.
- Recreation Facilities consist of Iargo Springs, Canoer's Memorial, and Lumberman's Monument.
- Peaking Operations

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- Cooke Dam listed on National Register of Historic Places (NRHP)
- Considerable Public Recreation use on Au Sable River
- Majority public lands (USFS) and limited private property adjacent to shoreline

Future License Conditions

- Operations monitoring/automation
- Recreation enhancements
- RTE Species Wildlife Management Plans
- Sediment Management
- Consult with USFS
- Land Management plan for buffer lands
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- Historic Properties Management Plan
- Retirement study
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Fish passage requirements
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled “Cooke Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo,” The interior of the powerhouse structure was given a 'Green' rating, indicating that major repair will not be needed for about 10 to 20 years. However, the exterior powerhouse was given a rating of ‘Blue,’ corresponding to 5 to 10 years until major repairs are needed. The ‘blue’ rating is due to deterioration of the left exterior concrete powerhouse and Unit #3 penstock exterior wall. It is recommended that destructive testing be performed to evaluate the concrete and the potential extent of rehabilitation.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder between May and July 2018 and consisted of an assessment of the concrete features/structures (Downstream Left Embankment Retaining Wall, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Log Chute, Powerhouse Apron, Spillway Abutment, Downstream Spillway Apron, Spillway Structural Walkway Deck, Training Wall, Tumble Bay and Spillway, Upstream Left Wing Wall, Upstream Right Wing Wall, Upstream Spillway Apron, Upstream Spillway Piers) and spillway structural walkway. The findings were summarized in a condition assessment report for Cooke Hydroelectric Dam (dated January 4, 2019).

The key findings from the Cooke condition assessment identified two site features (the right downstream embankment retaining wall and the log chute) that were rated as YELLOW (3 to 5 years before major repairs or replacement is necessary). Two site features (the left and right upstream wing walls) were rated as BLUE (5 to 10 years before major repairs or replacement is necessary). Other structures that were inspected during this condition assessment and are included in this report were given a GREEN rating (10 to 20 years before major repairs or replacement is necessary).

DIVE INSPECTION

- Upstream Powerhouse & Spillway, July 17, 2018:
    - Two horizontal cracks and one vertical open construction joint at the South retaining wall. Three concrete spalls were observed in the open construction joint.
    - The South wing wall has one vertical crack and three diagonal cracks.
    - The steel trash rack bars were deteriorated up to 10%. Trash racks were approximately 20% blocked with debris.
    - One diagonal crack was observed in the divider pier between the powerhouse and the spillway.
    - One concrete spall and one open vertical construction joint were observed in the north retaining wall. The North wing wall has one vertical crack and one concrete spall.
    - One horizontal crack was observed at the north divider pier at Bay #1.
- Downstream Powerhouse & Spillway, July 18, 2018:
    - Lifting chains and connectors in the upstream spillway were deteriorated by up to 10%.
    - One horizontal crack at the north retaining wall along the upstream spillway. One concrete spall at the construction joint between the wing wall and the North retaining wall.
    - Trash rack bars are deteriorated up to 10% throughout. Trash racks in Bay #3 are completely blocked with Zebra mussels. Bay 3 is a dead bay with not generating unit installed.
    - One concrete spall at the pier between Bay #s 2 and 3.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

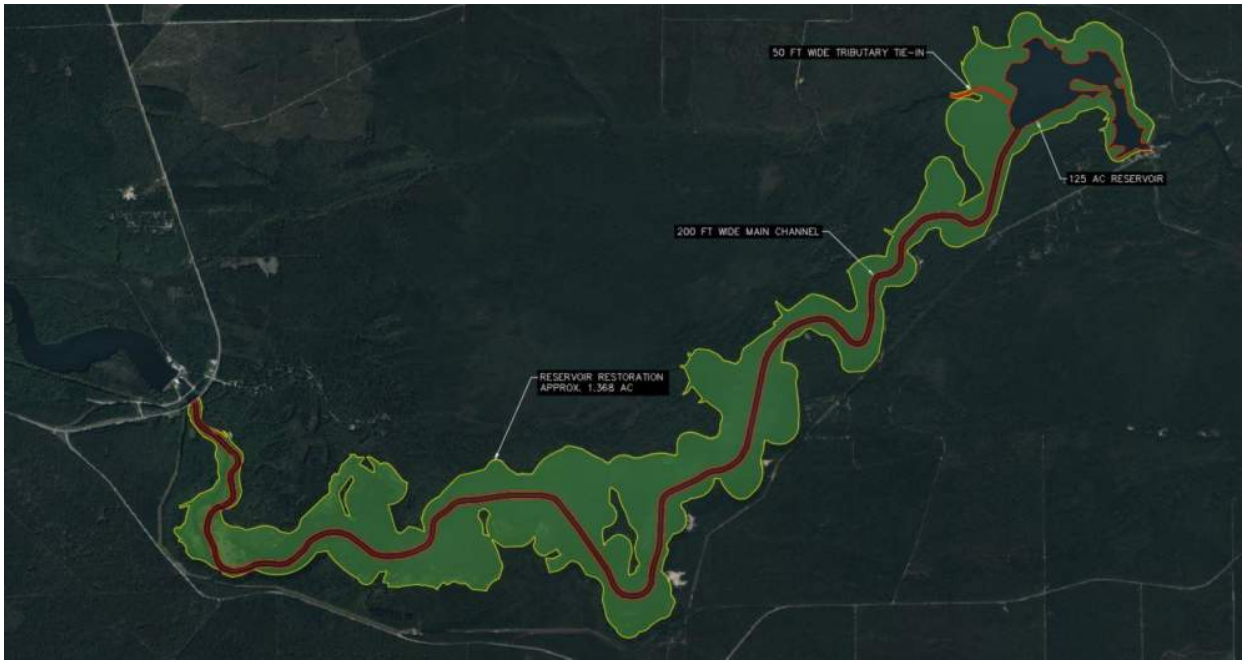
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require a significant amount of capital to implement.

Current Remediation Projects in LTFP

- Headgate Replacement – Capital
- Plant Lighting Upgrade – Capital
- Midslope Retaining Wall Replacement – Capital
- Remote Spillgate Control Installation – Capital
- Right Embankment Retaining Wall Replacement – Capital
- Left Embankment Core Wall Addition – Capital
- Right Embankment Core Wall Slab Extension – Capital
- Spillway Hoist Replacement – Capital
- Electrical Safety Upgrade – Capital
- Step Up Transformer (GSU) Replacement – Capital
- Station Battery Replacement – Capital
- Powerhouse Window Replacement – Capital
- Apron Joint/Crack Sealant -O&M
- Log Chute Concrete Repair – O&M
- Powerhouse Divider Wall Pier Repair – O&M
- Unit 1 Intake Deck Concrete Repair – O&M
- Right and Left Upstream Wingwall Repair – O&M

Remediation Projects not in LTFP

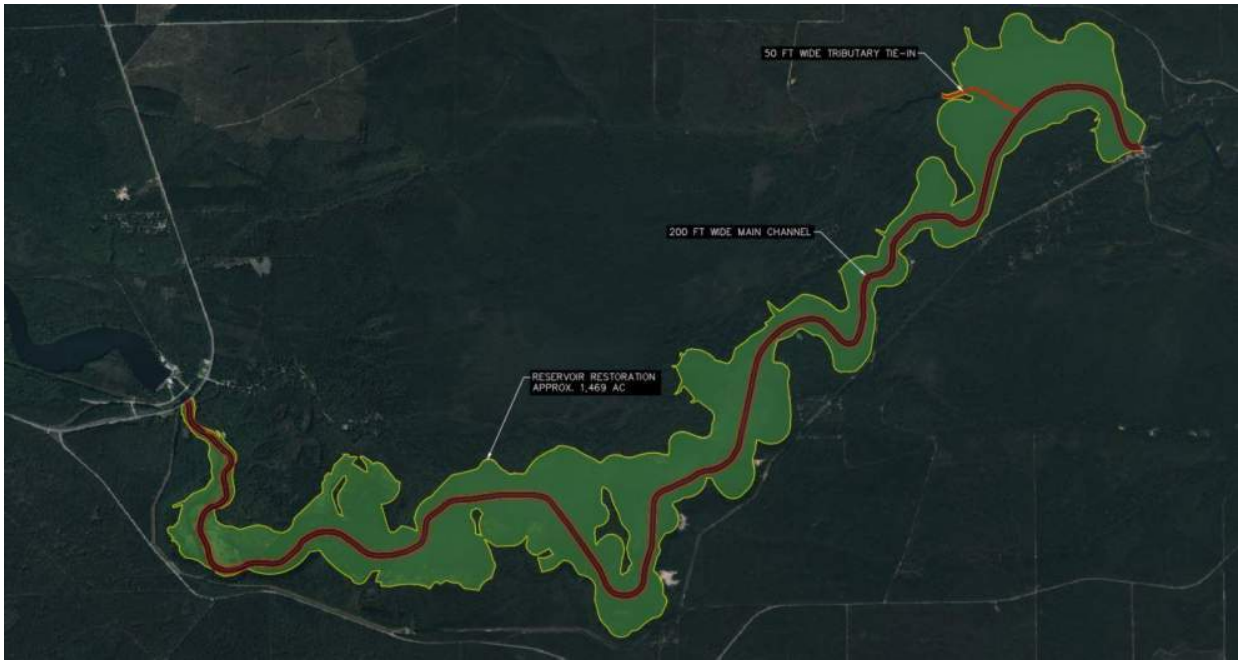


- Concrete Hallway Chambers Remediation
- Powerhouse Basement Concrete Repairs
- Units 1, 2, and 3 Concrete Repairs

Generation

The Cooke development consists of 3 units with a calculated maximum generation capacity of 78,840 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 27,803 MWH, contributing 6% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 39,568 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - It is unlikely that the Cooke Dam impoundment will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
  - Installing a new dam/weir structure will preserve the secondary barrier for invasive species attempting to travel upstream from Lake Huron.

- Cons/Risks
    - Auxiliary spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - The 46 kV substation will need to be relocated outside of the floodplain.
    - May also still cause sediment transport issues. The Cooke Dam should be removed after removal of the Mio, Alcona, Loud and Five Channels dams and before the Foote Dam so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
        - The Cooke Dam also received a State Historic Marker in 2005 and is on the National Register of Historic Places, which may create additional resistance to the dam removal.
    - Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir extents.
    - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to agriculture, uninhabited buildings, structures, or township or county roads, where environmental degradation would be minimal, and where danger to individuals is slight or nonexistent. This opinion is based on the following considerations:
        - Two inhabited residential properties located along left riverbank 1,600 FT downstream of dam (located at high enough elevation to not be at a significant risk of damage)
        - Au Sable River Camping sites located along left and right banks starting at approximately 4,000 FT downstream of dam

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
    - Habitat can be restored along the entire footprint of the dam.
  - Eliminates sediment transport issues
  - It is unlikely that the Cooke Dam impoundment will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.

- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Cooke Dam should be removed after all upstream dams and before all downstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - The 46 kV substation will need to be relocated outside of the floodplain.
    - The dam serves as a secondary barrier to invasive species attempting to travel upstream from Lake Huron behind Foote Dam. Additional costs may be required to install sea lamprey control barriers (such as the FishPass system).
    - Public disapproval of this option due to its socioeconomic and recreational impact.
        - The Cooke Dam also received a State Historic Marker in 2005 and is on the National Register of Historic Places, which may create additional resistance to the dam removal.
    - Significant planning and analysis required to determine how to manage existing recreational features.

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
    - The 46 kV substation could also remain in place under this option.
    - Keeping the dam in place will preserve the secondary barrier for invasive species attempting to travel upstream from Lake Huron.
- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
        - Future repairs to dam structure.
    - Fish passage installation required.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender.

E-2 COOKE DAM NO-POWER GENERATION SCENARIO CONCEPTUAL ESTIMATE

Consumers Energy
Cooke Dam
Decommissioning Cost Evaluation - Non Power Removal

Category	Cost Activity	Unit	WSP Unit Cost	Quantity	WSP Opinion of Cost
Decommissioning and Demolition	Leave Powerhouse Intact	LS	$347,101.00	1	$ 347,101

	Grading & Surface Preparation/Amendments	AC	$ 6,700.00	1,469	$ 9,842,300
	Channel creation: Riffle section at downstream tie in	CY	$ 150.00	16,889	$ 2,533,334
	Subtotal				**$ 78,436,836**
Project Indirect	Owner's Cost				$ 11,765,526
	Engineering and Permitting				$ 3,488,275
	Construction Management & Biological Monitoring				$ 1,568,737
Contingency	Contingency				$ 7,843,684
Total Project Costs					**$ 103,103,058**

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database.

APPENDIX

F FOOTE DAM HYDROELECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

F-1 FOOTE DAM SITE SUMMARY

Site Characteristics

- Two, 55-feet-high earth embankment dam sections, each with a concrete core wall.
- A 30-feet-high concrete spillway with three, 14.5-feet-high steel radial gates and a concrete-lined discharge channel extending approximately 210 feet downstream with a 12-feet-high concrete weir located approximately 65 feet downstream.
- A reservoir with a normal surface area of 1,702 acres at elevation 639.2 feet (U.S. Geological Survey [USGS] datum) and a gross storage of 32,380 acre-feet.
- A concrete and masonry powerhouse containing three generating units with a total installed capacity of 7,229 kilowatts (kW).
- A 25-feet-long concrete apron in the tailrace with concrete and sheet pile (right downstream side only) retaining walls extending 165 and 290 feet downstream, respectively.
- Associated appurtenant structures.
- Run-of-River operations

Relicensing Issues

- Major license (referenced in License Order, subject to form L-5)
- Water Quality out of compliance for temp and potentially dissolved oxygen (DO)
- Considerable Public Recreation use on Au Sable River. Foote Reservoir known for fishing and boating as most downstream reservoir and proximity to Lake Huron
- Majority public lands (USFS) and limited private property adjacent to shoreline
- Reservoir closest to Oscoda and Au Sable (population centers) on Lake Huron and potential for more public input different from reservoirs and reaches higher in the watershed (regional differences in interest areas)

Future License Conditions

- Operations monitoring/automation
- Water Quality mitigation/monitoring
- Recreation enhancements
- RTE Species Wildlife Management Plans
- Sediment Management
- Consult with USFS
- Land Management plan for buffer lands
- Fish stocking/funding
- Fish Passage (trap & truck or fish ladder)
- Land/Shoreline Management
- Historic Properties Management Plan
- Retirement study
- Operational restrictions to run-of-river

Risks to Operating under another 50-year License

- Fish passage requirements or mitigation
- Temperature and potential DO exceedances
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Foote Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo," The exterior powerhouse structure was given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. However, the interior powerhouse was given a rating of 'Yellow,' corresponding to 3 to 5 years until major repairs are needed. The 'Yellow' rating is due to observed cracks and enlarged joints which indicate movement of the structure, particularly at the downstream left corner of the powerhouse. It is recommended that additional monitoring of the observed movement be performed moving forward, including periodic photographic documentation and additional survey points. It is also recommended that a thorough inspection of the interior crane be performed by a firm that certifies cranes.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder between June and July 2018 and consisted of the concrete features/structures (Downstream Left Embankment Retaining Wall, Downstream Powerhouse Apron, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Emergency Spillway Concrete Sloping Wall, Log Chute, Spillway Abutment, Downstream Spillway Apron, Spillway Structural Walkway Deck, Training Wall, Tumble Bay and Spillway, Upstream Left Wing Wall, Upstream Powerhouse Piers, Upstream Right Wing Wall, Upstream Spillway Apron, Upstream Spillway Piers) and spillway structural walkway. The findings were summarized in a condition assessment report for Foote Hydroelectric Dam (dated January 4, 2019).

The key findings from the Foote condition assessment identified two site features (the log chute and training wall) that are rated as BLUE (5 to 10 years before major repairs or replacement is necessary). In addition, the vertical joint at the transition between the sloped and horizontal portions of the downstream right embankment retaining wall should be repaired of damaged concrete and the joint cleaned and re-sealed. Less than 50% of the emergency spillway concrete sloping was visible and it is recommended the wall be cleared of vegetation overgrowth so that the remainder of the wall can be properly inspected. Golder recommended that the spillway structural walkway

deck be refinished in areas with protective coating loss to ensure corrosion does not reduce the design life of the structure, as well as cleaning and re-sealing of the joints between slabs. The joint between the wing walls and abutments on both the left and right wing walls should continue to be monitored during routine dive inspections. The grout seal for an old cofferdam used for construction on the upstream side of the spillway has exhibited spalling and should continue to be monitored to ensure the irregular surface does not cause advanced spalling of the existing apron concrete. Cleaning and resealing of the joints between the upstream spillway piers and structural walkway deck that were observed to have loose and separated sealant is also recommended. Other structures that were inspected during this condition assessment and included in this report were given a Green rating (10 to 20 years before major repairs or replacement is necessary).

DIVE INSPECTIONS

- Powerhouse, July 30, 2018:
    - One concrete spall and an open construction joint at the upstream south retaining wall.
    - The trash racks are deteriorated up to 10%.

  - The upstream concrete divider pier between bays 2 and 3 spalled at the water surface.
  - One concrete spall and an open vertical construction joint at the downstream south retaining wall.
  - One vertical concrete crack between the log chute and draft tube bay 1.
  - Construction joints in the downstream apron slab at several locations, and 7 areas of concrete spalling.
- Spillway, July 31, 2018:
  - One open construction joint between the north upstream retaining wall and the north wing wall.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require as significant amount of capital to implement.

Current Remediation Projects in LTFP

- ADA Ramp Replacement – Capital
- Units 1, 2, and 3 Governor Replacement – Capital
- Fish Net Frame Removal – Capital
- Spillway Hoist Replacement – Capital
- Trash Rack Ergonomics Project – Capital
- Electrical Safety Project – Capital
- Station Battery Replacement – Capital
- Unit 2 Wicket Gate Replacement – Capital
- Right Steel Sheet Pile Cut Off Wall PMF Overtopping Replacement – Capital
- Auxiliary Spillway Pilot Channel and Embankment Crest Grading – O&M
- Downstream Concrete Repairs – O&M

Remediation Projects not in LTFP

- Emergency Spillway
- Powerhouse Basement Leaks
- Units 1 and 3 Headgate Realignment
- Units 1, 2, and 3 Concrete Repairs
- Left Downstream Powerhouse Wall Remediation/Repair

Generation

The Foote development consists of 3 units with a calculated maximum generation capacity of 78,840 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 30,711 MWH, contributing 7% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 61,642 MWH.

Surrendering (projected to 2035 at end of licensing period and following FERC decommissioning process)

Decommissioning (Partial)

- Pros
    - Reduces legal liability and maintenance of existing facilities.
    - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
    - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
    - It is unlikely that the Foote Dam will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
    - Installing a new dam/weir structure will preserve the primary barrier for invasive species attempting to travel upstream from Lake Huron.
- Cons/Risks
    - Emergency spillway and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Water quality (temperature and potential DO) may still be out of compliance for cold water fisheries under License Article 405.
    - May also still cause sediment transport issues. The Foote Dam should be removed after removal of all upstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
    - Fish passage system should be designed with consideration to allow desirable species (Lake Sturgeon) and prevent non-desirable species (Sea Lamprey) from upstream migration.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
        - Archeological sites are also reported to be contained within the project area, which may create additional resistance to the dam removal.
    - Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir extents.
        - There are several homes located along the reservoir edge that are part of the Bissonette subdivision and Seven Mile Hill HOA, many of which have their own private boat docks.
    - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to agriculture, uninhabited buildings, structures, or township or county roads, where environmental degradation would be minimal, and where danger to individuals is slight or nonexistent.

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
    - Habitat can be restored along the entire footprint of the dam.
  - Eliminates issues of water quality (temperature and potential DO).
  - Eliminates sediment transport issues
  - It is unlikely that the Foote Dam impoundment will contain contaminated PFAS sediments due to its distance downstream from the Camp Grayling Superfund site.
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Foote Dam should be removed after all upstream dams so that downstream re-sedimentation does not impact previously removed and restored dam sites.
  - The dam serves as a primary barrier to invasive species attempting to travel upstream from Lake Huron. Additional costs may be required to install sea lamprey control barriers (such as the FishPass system by the Great Lakes Fishery Commission).

- Public disapproval of this option due to its socioeconomic and recreational impact.
    - Archeological sites are also reported to be contained within the project area, which may create additional resistance to the dam removal.
- Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir extents.
    - There are several homes located along the reservoir edge that are part of the Bissonette subdivision and Seven Mile Hill HOA, many of which have their own private boat docks.

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
    - Keeping the dam in place will preserve the primary barrier for invasive species attempting to travel upstream from Lake Huron.
- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
        - Future repairs to dam structure.
    - Fish passage installation required.
    - Water quality (temperature and potential DO) may still be out of compliance for cold water fisheries under License Article 405. Significant costs may be required bring the water temperature into compliance to support cold water fisheries.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Putting this project on the market as part of a large portfolio is a near term action that can potentially provide an exit strategy from the asset. There is time before having to make a decision on relicensing or surrender to test the market and negotiate with potential buyers.

1 EXECUTIVE SUMMARY

Consumers Energy Company (Consumers) owns and operates 13 river hydro dam facilities located on the Muskegon, Manistee, Grand, Au Sable, and Kalamazoo Rivers. The average age of these assets is 106 years old and much of each site is original construction and equipment. Consumers would need to start relicensing 11 of the 13 projects with filings signaling their intentions no later than June 30, 2029, meaning a plan for the assets should be in place within the next few years to prepare for filing with Federal Energy Regulatory Commission (FERC). In addition, FERC has recently updated their Part 12 inspection requirements. The revised inspections put more emphasis on Potential Failure Mode Analysis, updated Probable Maximum Flood, and Semi-Quantitative Risk Analysis level 2 effort for each site. These enhanced regulations require subject matter experts and facilitators to complete portions of the work.

Consumers also conducts routine inspections and commissioned studies investigating the overall conditions of the facilities. Although not comprehensive, the assessments indicate the assets are in 'fair' condition but recognizes the current operations as run-of-river is inconsistent with the original peaking designs conceding efficiency and potential generation revenue. The combination of aging assets, increasing regulatory requirements which have resulted in potentially costly upgrades to some of the Project's spillways, system operations, and expected spend on necessary maintenance to keep the plants operating has raised the question of how to extract the best value out of these assets. To achieve this goal, Consumers hired WSP USA, Inc. (WSP) to prepare the 2023 Hydropower Roadmap (Roadmap) for the 13 hydroelectric dam sites which reviewed Consumers' provided facility reports and analyzed different outcome scenarios and characterized how to achieve them. This Roadmap analyzed six scenarios that included two for relicensing, three for surrendering the license, and one to investigate divesting. Within this pursuit, an additional goal of developing an economic model as a tool to rank the potential outcomes was later added.

This report details the surrendering considerations and pricing considered in the roadmap for 1 of the 13 hydropower facilities, Calkins Bridge Dam, located within the Kalamazoo River Watershed, in Allegan County.

Three surrender scenarios with specific assumptions were considered in preparing the cost estimates for each surrender option:

1. Surrender– No-Power Generation: The no-power generation scenario evaluates surrender of the FERC license while not removing the dam structure. The powerhouse and spillway would be modified to maintain safe flows through the system while disconnecting generation equipment. The dam would remain in place and current reservoir levels would be maintained. Additional capital improvements would be required for long term compliance with dam safety regulations.
2. Surrender and Decommission – Partial Removal: The partial removal scenario evaluates partial removal of the dam via reduction of the earthen dam structure with full removal of the powerhouse and generation facilities. This scenario evaluates the potential to leave some form of upstream reservoir system while developing a new weir control structure. This structure would be designed to fall under state regulations (Natural Resources and Environmental Protection Act (NREPA), Part 315, Dam Safety), not FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir and to prevent the proliferation of invasive species such as the sea lampreys.
3. Surrender and Decommission - Full Removal: The full removal scenario evaluates the complete removal of the dam and reservoirs. The reservoirs would be drained, powerhouse/generation facilities and earthen dam structures fully removed, and the upstream channel and floodplain restored to pre-dam conditions.

For the subject facility and scenario, a class 5 cost estimate was prepared in Q4 2022 dollars, identifying and quantifying the value of the plant's assets and estimate of the cost of utility separation, decommissioning and demolition, abatement and regulated material removal, environmental and restoration work of the Kalamazoo River, as well as associated project indirect costs and recommended contingency. Schematics utilized for the evaluation of the Surrender and Decommission – Partial and Full Removal for how the reservoir may be reshaped in the decommissioning restoration are presented. Additional assumptions and limitations by site are presented herein.

2 INTRODUCTION

Consumers Energy Company (Consumers) owns and operates 13 river hydro dam facilities located on the Muskegon, Manistee, Grand, Au Sable, and Kalamazoo Rivers. The average age of these assets is 106 years old and much of each site is original construction and equipment. Consumers would need to start relicensing 11 of the 13 projects with filings signaling their intentions no later than June 30, 2029, meaning a plan for the assets should be in place within the next few years to prepare for filing with Federal Energy Regulatory Commission (FERC). In addition, FERC has recently updated their Part 12 inspection requirements. The revised inspections put more emphasis on Potential Failure Mode Analysis, updated Probable Maximum Flood, and Semi-Quantitative Risk Analysis level 2 effort for each site. These enhanced regulations require subject matter experts and facilitators to complete portions of the work.

Consumers also conducts routine inspections and commissioned studies investigating the overall conditions of the facilities. Although not comprehensive, the assessments indicate the assets are in 'fair' condition but recognizes the current operations as run-of-river is inconsistent with the original peaking designs conceding efficiency and potential generation revenue. The combination of aging assets, increasing regulatory requirements which have resulted in potentially costly upgrades to some of the Project's spillways, system operations, and expected spend on necessary maintenance to keep the plants operating has raised the question of how to extract the best value out of these assets.

To achieve this goal, Consumers hired WSP USA, Inc. (WSP) to prepare the 2023 Hydropower Roadmap (Roadmap) for the 13 hydroelectric dam sites which reviewed Consumers' provided facility reports and analyzed different outcome scenarios and characterized how to achieve them. This Roadmap analyzed six scenarios that included two for relicensing, three for surrendering the license, and one to investigate divesting. Within this pursuit, an additional goal of developing an economic model as a tool to rank the potential outcomes was later added. This report details costs and considerations prepared for 1 of the 13 hydropower facilities, Calkins Bridge Dam, located along the Kalamazoo River system in Allegan County.

The Kalamazoo River system is the seventh largest river basin in Michigan. It is in southwest Michigan and incorporates 9 counties including Hillsdale, Jackson, Eaton, Calhoun, Barry, Kalamazoo, Kent, Ottawa, Van Buren, and Allegan counties. The Kalamazoo River watershed drains more than 2,020 square miles of land area, and approximately 899 miles of tributaries flow directly into the mainstream.

The three surrendering scenarios include:

- Surrender – No-Power Generation
- Surrender and Decommission – Partial Removal
- Surrender and Decommission – Full Removal

The objective of the conceptual decommissioning cost estimate is to identify the value of the plant's assets and estimate of the cost of utility separation, decommissioning and demolition, abatement and regulated material removal, environmental work, and restoration of the Kalamazoo River, as well as associated project indirect costs and recommended contingencies.

2.1 CALKINS BRIDGE DAM

The Calkins Bridge dam (FERC Project Number 785), located in the Kalamazoo River in Valley Township, Allegan County, Michigan consists of a 30-foot-high, 1,335-foot-long earth embankment dam section with 132 feet long concrete spillway with six steel radial gates which discharge to a concrete apron extending approximately 54 feet downstream. The reservoir, with a normal surface area of 1,550 acres at elevation 615.0 feet (U.S. Geological Survey [USGS] datum), has a gross storage of 17,000 acre-feet.

The Calkins Bridge Hydroelectric Project features a public road, Allegan Dam Road, that crosses the top of the earth embankment dam and spans the spillway. Any plans for partial or complete removal must account for the bridge over the

spillway. Options 2 and 3 include an estimated cost for constructing a new seven-span bridge and associated roadway. The actual cost for a new river crossing could vary significantly based on the breach width needed to handle a 100-year flow. If decommissioning occurs, more detailed information on valley geology, topography, and the extent of the restored river's 100-year floodplain would be necessary to estimate costs more accurately.

3 STUDY APPROACH

3.1 ASSUMPTIONS

WSP analyzed the costs for three scenarios involving the surrender of the hydropower facilities before the current license expires. These scenarios include 1) Surrender – No-Power Generation: 2) Surrender and Decommission – Partial Removal; and 3) Surrender and Decommission – Full removal. Detailed description of these alternatives are as follows:

Surrender – No Power Generation Operation

The no-power generation scenario evaluates surrender of the FERC license while not removing the dam structure. The powerhouse and spillway would be modified to maintain safe flows through the system while disconnecting generation equipment. The dam would remain in place and current reservoir levels would be maintained. Additional capital improvements would be required for long term compliance with dam safety regulations.

Surrender and Decommission - Partial Removal

The partial removal scenario evaluates the partial removal of the dam by reducing the earthen dam structure while fully removing the powerhouse and generation facilities. This reduction would create a sufficient breach to pass the 100-year flood through the reestablished river channel, ensuring that the incremental rise at the dam site would be less than 0.10 foot. This scenario also considers the potential to maintain some form of upstream reservoir system while developing a new weir control structure.

This structure would be designed to fall under state regulations (Natural Resources and Environmental Protection Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir and to prevent the proliferation of invasive species such as the sea lampreys. Exposed sediments and newly exposed shoreline would be stabilized and re-vegetated.

Schematics for the partial removal scenario for the reservoir and dam structure are provided in Appendix A.

Surrender and Decommission - Full Removal

The full removal scenario evaluates the complete removal of the dam and reservoirs. The reservoirs would be drained, powerhouse/generation facilities, earthen dam, concrete spillway, tailrace and retaining structures fully removed, and the upstream channel and floodplain restored to pre-dam conditions. To minimize the transport and improve stabilization of the sediment within the reservoir, the reservoir would be drawn down in a controlled manner. Hydraulic dredging would be performed to approximate the river's original meander to allow the river to re-establish its course through the current reservoir. Contaminated sediments, if present, would be hauled off site and disposed of properly.

Schematics for the full removal scenario for the reservoir reservation and dam structure are provided in Appendix A.

3.2 LIMITATIONS

- Prior costs provided by Consumers for these scenarios and developed by Kiewit Corporation in 2022, as available, and Mead & Hunt (M&H) in 2021 were used as the foundation of these estimates. Sequencing of work follows the descriptions as detailed by M&H with additional measures incorporated following removal as part of the reservoir restoration. Estimates were supplemented and expanded based on similar experiences from other applicable dam removal projects.
- Information related to sediment volumes and characterization are estimated and assumed based on watershed research for potential hazardous contamination. As no data is available at this time, there is significant risk associated with the uncertainty to the volumes and level of contamination for management. Unless documentation of known hazardous spills were identified for the watershed, it was considered as a mix of non-

contaminated and contaminated non-hazardous sediments for removal and disposal, as detailed herein. Sediment investigations would occur after a decision to surrender and decommission were approved.

- These estimates are based on Q4 2022 dollars at the time of preparation.
- Cost estimates, by nature, are as best as the information available at the time of preparation. Estimates should be reconsidered and updated as new information is obtained and as market conditions change.
- Additional assumptions and limitations considered for each cost item to derive the presented unit pricing and quantity are detailed herein.

4 COST ESTIMATE SUMMARY

4.1 CLASS ESTIMATES

Although hydropower costs are highly site-specific with many factors contributing to cost uncertainty, costs accuracy is generally assumed to increase as project development nears completion. As such construction stage cost estimates are necessarily considered the most accurate and are quantitatively defined as such by Association for the Advancement of Cost Engineering (AACE). The level of information or considerations prepared for this independent evaluation, with limitations, would be considered as Class 5 estimate per AACE.

4.1.1 CLASS 5 ESTIMATE

This is known as the rough order of magnitude (ROM) estimate. It is used for the initial screening projects for capital expenditure planning. Since several projects are initially available, estimating each would require a tremendous amount of time and effort. Given the limited preparation, ballpark figures are usually accepted to make business plan projections. Class 5 estimates are drawn from limited information which is about 0 to 2% of the project definition. The information may be nothing more than a basic description of the plant or process, capacity, and location. That is why its accuracy ranges -50% on the low side and +100%on the high side.

Class 5 cost estimate accuracy range: -50% to +100%

Stochastic cost estimating methods are used for obtaining a Class 5 estimate. Examples of these are cost/capacity curves, rule of six-tenths, Lang factor method, scale of operation factors, and cost indices. These techniques use parametric cost estimation methods to deduce the total cost of a given project.

4.2 COST ESTIMATE SUMMARIES

Costs for each surrender scenario were calculated for (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. Detailed descriptions for each item under each scenario are provided below.

All units used in the cost estimate are U.S. Standard and all costs are in US Dollars (4th Quarter 2022 levels). The conceptual decommissioning cost estimates for the subject dam are included in Appendix A.

4.2.1 QUANTITIES AND UNIT COSTS

Quantities of pieces of equipment and/or bulk material commodities used in the cost estimates were intended to be reasonable and representative of projects of this type. Material quantities were prepared by M&H in 2021 for categorial items included within their estimate. As appropriate, WSP simplified unit measurements and unit pricing for subject activities. For additional activity items incorporated by WSP, quantities were estimated from the schematic renderings prepared for the subject site and included within Appendix A, as detailed below. Upon determining corrective unit quantities and unit costs, cost components for each activity were determined by the multiplication of the unit quantity by unit cost, rounded to the nearest whole dollar.

4.2.2 UNCERTAINTY AREAS

This estimate will be based on similar experiences from other projects. Therefore, some specific information about the subject site is unknown. Additional studies would be needed to determine physical and chemical characteristics of soils and sediments, potential costs required to manage and dispose of potentially contaminated sediments upstream of the structures, type of vegetation and presence of non-native species, archaeological resources and historic structures, hydrology and hydraulic characteristics, as well as ecology and biology upstream and downstream of the structures.

4.2.3 CALKINS BRIDGE HYDROELECTRIC PROJECT COST ESTIMATE ACTIVITIES

Table 4.1 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.1 Calkins Bridge Hydrolelectric Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Remove Substation		X	X
	Remove Lines from Plant to Substation		X	X
Decommissioning and Demolition	Leave Powerhouse Intact	X		
	Remove Security Fencing		X	X
	Remove Septic Tank/Drain Field		X	X

Contingency	Contingency	X	X	X

Remove Substation

Lump sum cost was taken from the M&H cost estimate for removal of the substation. The partial and full removal options assume that the Calkins Bridge Plant would be demolished and therefore, local transmission would no longer be required.

Remove Lines from Plant to Substation

Lump sum cost taken from M&H cost estimate for removal of buried cable. The partial and full removal options assume that the Calkins Bridge Plant would be demolished and therefore, electric lines between the powerhouse and substation would be removed.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H cost estimate. The powerhouse structure would be left in place under the non-power operation option. Once the electrical generating equipment had been removed, water intake into the power plant would be plugged with concrete and the power conduits beneath the powerhouse would be filled with sand.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Septic Tank/Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Removal of Right Downstream Sheet Pile Wall

Price per square foot was taken from the M&H estimate. For both the partial and full removal, the sheet pile wall would no longer be necessary and would therefore be removed.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 6 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove All Powerhouse Equipment

Lump sum cost was taken from the M&H estimate. Under the partial and full removal options, all the plant electromechanical equipment, controls, protection, and station transformers would be removed from the powerhouse and transported for off-site disposal.

Remove or Lay Up Equipment

Lump sum cost was taken from the M&H cost estimate. Under the non-power operation option, the turbine-generator would be disabled, and all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance would be decommissioned and laid-up in the powerhouse.

Demolish and Remove Concrete/Masonry

Price per cubic yard was taken from the estimate by M&H. Under the partial and complete removal scenarios, concrete and masonry associated with the dam and powerhouse structure will no longer be necessary and will be removed.

Remove Trash Racks

Cost per ton was taken from the M&H estimate. Under the partial and complete removal scenarios, trash racks will no longer be necessary and will be removed.

Remove Gates – Powerhouse

Cost per ton was taken from the M&H estimate. Under the partial and complete removal scenarios, gates will no longer be necessary and will be removed.

Remove Sheet Pile – Powerhouse

Price per square foot was taken from the M&H estimate. For both the partial and full removal, the sheet pile wall at the powerhouse will no longer be necessary and will be removed.

Demolish and Remove Concrete

Price per cubic yard was taken from the estimate by M&H. Under the partial and complete removal scenarios, concrete associated with the dam and powerhouse structure will no longer be necessary and will be removed.

Remove Gates – Spillway

Cost per ton was taken from the M&H estimate. Under the partial and complete removal scenarios, spillway gates will no longer be necessary and will be removed.

Remove Gate Hoist

Cost per ton was taken from the M&H estimate. Under the partial and complete removal scenarios, hoists will no longer be necessary and will be removed.

Remove Rails

Cost per ton was taken from the M&H estimate. Under the partial and complete removal of hoist rails will no longer be necessary and will be removed.

Remove Sheet Pile – Spillway

Price per square foot was taken from the M&H estimate. For both the partial and full removal, the sheet pile wall at the spillway will no longer be necessary and will be removed.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Drain Reservoir

Lump sum cost was taken from the M&H cost estimate. Under the partial and complete removal options, the reservoir would be drained in a controlled manner through the powerhouse and spillway during removal of the powerhouse structure. The removal will be staged and the effect of lowering the reservoir on project wetlands will be monitored monthly throughout the process. Removal of the spillway will require the installation of a temporary cofferdam.

Remove Earth Dam

Cubic yard unit price was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Remove Portion of Earth Dam to Create Sufficient Breach

Cubic yard unit price was taken from the M&H estimate for a similar structure. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Remove Accumulated Non-Contaminated Sediments

Cubic yard unit price was taken from the M&H estimate. It is assumed that the 250-foot-wide main channel will be re-established with limited dredging. WSP determined approximately 262,623 cubic yards of material will need to be removed to clear fine-grain sediments and re-establish the channel where necessary beyond the pilot channel. This amount is reduced under the partial removal scenario to 188,976 cubic yards to account for limited dredging within the new impoundment for the partial removal.

Remove Contaminated Soil (Superfund Site)

Cubic yard unit price was taken from the M&H estimate. Consideration of dredging operation only for removal and loading into a disposal truck of an initial layer of contaminated non-hazardous sediments at the onset of removal. Quantity considers a 12-inch layer of non-hazardous contaminated materials is removed from 50% of the reservoir area for disposal at a registered landfill accepting non-hazardous sediments for both the partial and full removal scenarios.

Disposal of Contaminated Soil

Unit cost consideration for transportation and disposal fee of non-hazardous contaminated sediments at an offsite facility accepting material.

New Bridge

Under partial and complete removal options, the existing Allegan Dam Road, which crosses the top of the earth embankment dam, would need to be replaced with a new, approximately 12,600 square foot bridge to span the river.

Roadway Reconstruction

Under the partial and complete removal options, the existing Allegan Dam Road, which crosses the top of the earth embankment dam, would need to be reconstructed.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Grading & Surface Preparation/Amendments

WSP added cost for grading and surface preparation/amendments for newly exposed sediments within the reservoir for floodplain restoration.

Channel Creation - Riffle Section at Downstream Tie In

This item involves the placement of river rock along a portion at the downstream limits of work for the riffle bed reconstruction. It is assumed that the riffle section will be 250-feet-wide, 500-feet-long, and 2-feet-deep for the partial and full. The river rock will be strategically placed to enhance the stability and functionality of the riffle, promoting better water flow and habitat conditions.

Seed Former Reservoir Bottom

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Plant Former Reservoir Bottom

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 100% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Apply Erosion Control Measures: Silt Fence

Price per linear foot and unit quantity derived from WSP project experience. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures: Rip RaCp Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 15% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the Kalamazoo River.

Bank Stabilization - Live Stakes and Jute Matting

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 85% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the Kalamazoo, as well as both banks for all tributary lengths.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot-drop and 3-foot-footer) and 4-foot-width.

Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 19-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 9-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Owner's Cost

An owner's cost of 15% of the construction subtotal, less the contaminated material disposal cost, was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $412,780 for the environmental/social impact study (prepared by M&H for the non-power evaluation) and $400,000 for design of a fish ladder were applied.

For the partial removal scenario, 3.5% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring & O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) were applied. These costs may be variable as the design develops and permit stipulations are identified.

Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.4 COST ESTIMATE RESULTS SUMMARY

The full conceptual decommissioning cost estimate for the subject dam site and scenario is provided in Appendix A. Table 4.2 provides a summary of total cost by category for Calkins Bridge Hydroelectric.

Table 4.2 Calkins Bridge Dam Cost Estimate Results Summary

DESCRIPTION	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	$338,549	$39,664	$39,664
Decommissioning and Demolition	$177,116	$3,757,012	$4,577,371
Abatement and Regulated Material Removal	-	$140,581,586	$140,581,585
Salvage	-	-	-
Environmental and Restoration	$950,000	$25,470,786	$36,065,673
Subtotal	**$1,465,665**	**$169,849,048**	**$181,264,293**
Project Indirect	$1,235,495	$7,997,006	$9,937,131
Contingency Cost	$146,567	$16,984,905	$18,126,429
Total Project Cost	**$2,847,727**	**$194,830,959**	**$209,327,853**

Note: Variation between totals in the estimates shown in this report and the April 2024 Road Map are due to the following:

1. Rounding of quantities to the next whole integer were applied in the estimates herein.

2. Verifications of quantity by unit price to equate to WSP Opinion of Costs, rounded to the next whole dollar were applied in the estimates herein.

APPENDIX

A CALKINS BRIDGE HYDROELECTRIC PLANT CONCEPTUAL DEMOLITION COST ESTIMATE

A-1 CALKINS BRIDGE HYDROELECTRIC DAM SITE SUMMARY

Site Characteristics

- A 30-feet-high earth embankment dam section totaling 1,335 feet in length.
- A 132-feet-long concrete spillway with six steel radial gates which discharge to a concrete apron extending approximately 54 feet downstream.
- A reservoir with a normal surface area of 1,550 acres at elevation 615.0 feet (U.S. Geological Survey [USGS] datum) and a gross storage of 17,000 acre-feet.
- A concrete and masonry powerhouse containing three generating units with a total installed capacity of 2,550 kilowatts (kW).
- A 58-feet-long concrete-lined tailrace with retaining walls.
- Associated appurtenant structures.
- Low Hazard classification dam: Allegan Dam Road crosses across the top of or near the dam with integrated structural connections to the dam incorporated into design.

Relicensing Issues

- Major license (referenced in License Order, subject to form L-3)
- Indiana bat & Kerner Blue butterfly potential
- Potential archaeological resources
- Considerable Recreation use and access from MDNR Facilities
- Popular fishery downstream of dam
- Shoreline management and private property ownership
- Sediment pollution from upstream super fund site.

Future License Conditions

- Operations monitoring, automation and compliance
- Water Quality mitigation/monitoring
- Recreation enhancements
- RTE Species Management Plans
- Land/Shoreline Management
- Historic Properties Management Plan
- Operational run-of-river

Risks to Operating under another 50-year License

- Fish ladder was blocked with a removable plug in 1999 is a likely topic to investigate in next relicensing; however, Allegan may be best without it to limit invasive fish access and due to toxic sediments and fish consumption advisories in the Kalamazoo River
- Potential for temperature and dissolved oxygen (DO) exceedances
- Continued responsibility to meet regulatory requirements.
    - Operational monitoring for run-of-river, lake levels, and gage and instrumentation
    - Lake Sturgeon Spawning Habitat Enhancement Plan and a Reservoir Drawdown Management Plan
    - Downstream fish passage protection (existing racks 1.5 inch spacing)
    - Water quality monitoring downstream of the project and analyzing sediments and fish tissue in Lake Allegan for various contaminants, including total mercury and polychlorinated biphenyls (PCBs).
    - Plan to monitor and, where appropriate, control or eliminate invasive species and to implement measures to protect the Indiana bat, including restrictions on removing dead or dying trees near the shoreline.
    - Implement a Historic Properties Management Plan
    - Recreation: majority of use and access is provided by MDNR
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites.
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled "Allegan Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo," The exterior and interior powerhouse structure was given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. While no immediate major repairs are required, additional monitoring of cracks along interior columns and displacement of the exterior walkway is recommended.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder on September 28, 2018 and consisted of the above-water concrete features/structures (Downstream Left Embankment Retaining Wall, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Left Wing Wall/Abutment, Log Chute, Right Wing Wall/Abutment, Spillway Abutment, Spillway and Downstream Spillway Piers, Spillway Structural Walkway Deck, Upstream Powerhouse Piers, Upstream Spillway Piers). The findings were summarized in a condition assessment report for Allegan Hydroelectric Dam (dated May 14, 2019).

The structures that were inspected during this condition assessment and are included in this report were generally found to be in good condition and given a Green rating (10 to 20 years before major repairs or replacement is necessary).

DIVE INSPECTION

- July 7, 2021, and August 10, 2022 Underwater Condition Assessment
    - The underwater portions of the Calkins Bridge Hydroelectric Dam in overall good condition. All features/structures inspected were given a green rating, indicating that that major repair will not be needed for about 10 to 20 years. Deficiencies were limited to minor spalls, concrete aggregate pop-outs, minor cracking, surface scaling/erosion, and concrete surface flaking.
    - A vertical crack was observed in the upstream right wingwall, which was not observed in the 2016 underwater inspection. Additional monitoring of a vertical crack in the upstream right wingwall is recommended every 5 years. Continued removal of debris from the upstream powerhouse trash racks and spillway is also recommended.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

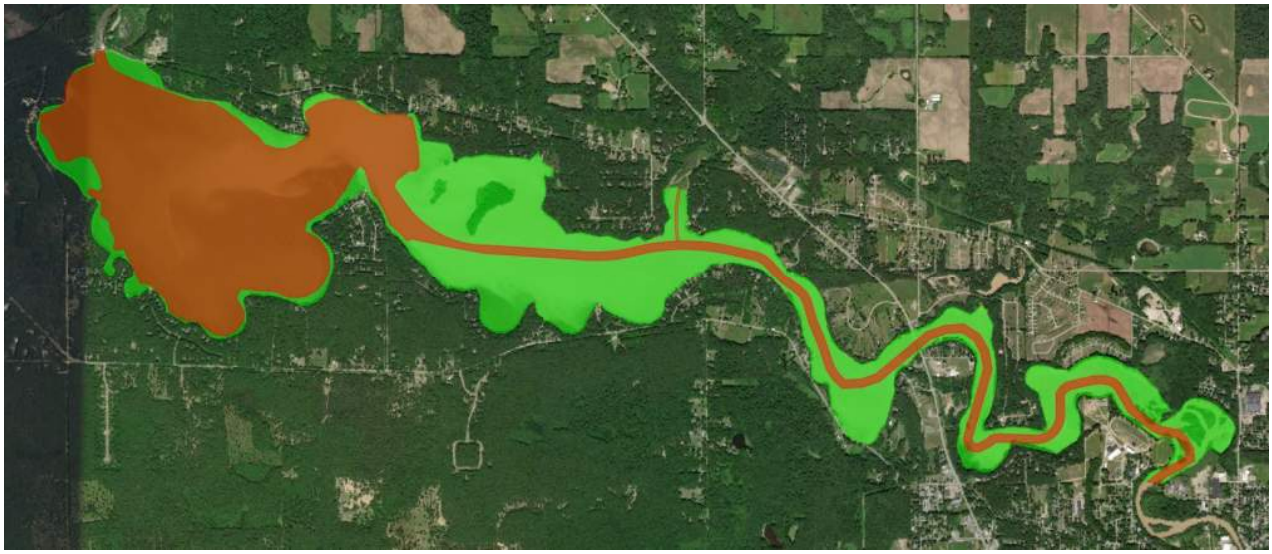
CURRENT PART 12 RECOMMENDATIONS:

Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require as significant amount of capital to implement.

Current Remediation Projects in LTFP

- Unit 1 Wicket Gate Replacement - Capital
- Powerhouse Roof Replacement – Capital
- Unit 3 Static Exciter Replacement – Capital
- 199 Breaker Replacement - Capital
- Units 1, 2, and 3 Governor Replacements – Capital
- Bridge Inspection (Structures and Improvements) – O&M
- Tailrace Access Safety Ergonomics – O&M

Remediation Projects not in LTFP



- Trash Rack Remediation
- Intake Concrete Repairs
- Powerhouse Concrete Repairs (From replacing wooden gates)
- Crane Remediation
- Units 1, 2, and 3 Concrete Repairs
- Back Deck Concrete Repairs
- Possible Bridge Replacement

Generation

The Allegan development consists of 3 units with a calculated maximum generation capacity of 22,338 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 13,628 MWH, contributing 3% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 15,432 MWH.

Surrendering (projected to 2040 at end of licensing period and following FERC decommissioning process)

Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
- Cons/Risks
  - This option will require significant coordination with regulatory agencies and external stakeholders due to changes in land use, majority of surrounding property is residential
  - The dam and reservoir fall within the Allied Paper, Inc./Portage Creek/Kalamazoo River Superfund site. Sediment characterization required to determine distribution of potential contamination. Requires coordination with EPA to determine responsibility of cost burden.
    - EPA is currently working to remediate the Kalamazoo River, but this portion has not yet been reached. The dam is in Area 6 of Operable Unit 5 (OU5) in the cleanup plan. The EPA has completed cleanup on OU2, OU3, and OU4. Currently there are cleanup plans in place for OU1, OU7, and Areas 1, 2, and 3 of OU5. None are in place for Area 6 OU5 at this time.
  - Fish passage installation required. Fish passage system should be designed with consideration to allow desirable species (Lake Sturgeon) and prevent non-desirable species (Sea Lamprey) from upstream migration.

- Water quality (temperature and DO) may still be out of compliance for cold water fisheries under License Article 405.
- May also still cause sediment transport issues.
- Public disapproval of this option due to its socioeconomic and recreational impact.
- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to agriculture, uninhabited buildings, structures, or township or county roads, where environmental degradation would be minimal, and where danger to individuals is slight or nonexistent.

Decommissioning (Full)

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
  - Habitat can be restored along the entire footprint of the dam.
  - Eliminates issues of water quality (temperature and DO).
  - Eliminates sediment transport issues

- Cons/Risks
    - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
    - Public disapproval of this option due to its socioeconomic and recreational impact.
    - Potential for contaminated sediment removal and transport which will create a significant cost burden.
    - Barrier system should be installed to prevent upstream migration of invasive species (sea lamprey and round goby); refer to FishPass System example by Great Lakes Fishery Commission.

License Surrendering (Non-Power Operation)

- Pros
    - Lower initial cost burden
    - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
    - Fish passage would not be addressed directly but requires installation of fish passage system; potential discontinuation of MDNR stocking.
    - Contaminated sediments do not need to be removed and transported offsite.
- Cons/Risks
    - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
        - Future repairs to dam structure.
    - Potential fish passage requirements.
    - Water quality (temperature and DO) may still be out of compliance for cold water fisheries under License Article 405. Upwelling system installation may add cost burden.
    - Transport of sediment and woody debris is also not improved through this option.

Divesting

Relicensing decision is further out than the Au Sable, Manistee, and Muskegon River projects. Putting this project on the market as part of a large portfolio is a near term action that can inform the next decisions. There is time before having to make a decision on relicensing or surrender.

1 EXECUTIVE SUMMARY

Consumers Energy Company (Consumers) owns and operates 13 river hydro dam facilities located on the Muskegon, Manistee, Grand, Au Sable, and Kalamazoo Rivers. The average age of these assets is 106 years old and much of each site is original construction and equipment. Consumers would need to start relicensing 11 of the 13 projects with filings signaling their intentions no later than June 30, 2029, meaning a plan for the assets should be in place within the next few years to prepare for filing with Federal Energy Regulatory Commission (FERC). In addition, FERC has recently updated their Part 12 inspection requirements. The revised inspections put more emphasis on Potential Failure Mode Analysis, updated Probable Maximum Flood, and Semi-Quantitative Risk Analysis level 2 effort for each site. These enhanced regulations require subject matter experts and facilitators to complete portions of the work.

Consumers also conducts routine inspections and commissioned studies investigating the overall conditions of the facilities. Although not comprehensive, the assessments indicate the assets are in 'fair' condition but recognizes the current operations as run-of-river is inconsistent with the original peaking designs conceding efficiency and potential generation revenue. The combination of aging assets, increasing regulatory requirements which have resulted in potentially costly upgrades to some of the Project's spillways, system operations, and expected spend on necessary maintenance to keep the plants operating has raised the question of how to extract the best value out of these assets. To achieve this goal, Consumers hired WSP USA, Inc. (WSP) to prepare the 2023 Hydropower Roadmap (Roadmap) for the 13 hydroelectric dam sites which reviewed Consumers' provided facility reports and analyzed different outcome scenarios and characterized how to achieve them. This Roadmap analyzed six scenarios that included two for relicensing, three for surrendering the license, and one to investigate divesting. Within this pursuit, an additional goal of developing an economic model as a tool to rank the potential outcomes was later added.

This report details the surrendering considerations and pricing considered in the roadmap for 2 of the 13 hydropower facilities located within the Manistee River Watershed, including the including Hodenpyl Dam in Wexford County, and Tippy Dam in Manistee County.

Three surrender scenarios with specific assumptions were considered in preparing the cost estimates for each surrender option:

1. Surrender– No-Power Generation: The no-power generation scenario evaluates surrender of the FERC license while not removing the dam structure. The powerhouse and spillway would be modified to maintain safe flows through the system while disconnecting generation equipment. The dam would remain in place and current reservoir levels would be maintained. Additional capital improvements would be required for long term compliance with dam safety regulations.
2. Surrender and Decommission – Partial Removal: The partial removal scenario evaluates partial removal of the dam via reduction of the earthen dam structure with full removal of the powerhouse and generation facilities. This scenario evaluates the potential to leave some form of upstream reservoir system while developing a new weir control structure. This structure would be designed to fall under state regulations (Natural Resources and Environmental Protection Act (NREPA), Part 315, Dam Safety), not FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir and to prevent the proliferation of invasive species such as the sea lampreys.
3. Surrender and Decommission - Full Removal: The full removal scenario evaluates the complete removal of the dam and reservoirs. The reservoirs would be drained, powerhouse/generation facilities and earthen dam structures fully removed, and the upstream channel and floodplain restored to pre-dam conditions.

For each facility and scenario, a class 5 cost estimate was prepared in Q4 2022 dollars, identifying and quantifying the value of the plant's assets and estimate of the cost of utility separation, decommissioning and demolition, abatement and regulated material removal, environmental and restoration work of the Manistee River, as well as associated project indirect costs and recommended contingency. Schematics utilized for the evaluation of the Surrender and Decommission – Partial and Full Removal for how the upper reservoir may be reshaped in the decommissioning restoration are presented. Additional assumptions and limitations by site are presented herein.

2 INTRODUCTION

Consumers Energy Company (Consumers) owns and operates 13 river hydro dam facilities located on the Muskegon, Manistee, Grand, Au Sable, and Kalamazoo Rivers. The average age of these assets is 106 years old and much of each site is original construction and equipment. Consumers would need to start relicensing 11 of the 13 projects with filings signaling their intentions no later than June 30, 2029, meaning a plan for the assets should be in place within the next few years to prepare for filing with Federal Energy Regulatory Commission (FERC). In addition, FERC has recently updated their Part 12 inspection requirements. The revised inspections put more emphasis on Potential Failure Mode Analysis, updated Probable Maximum Flood, and Semi-Quantitative Risk Analysis level 2 effort for each site. These enhanced regulations require subject matter experts and facilitators to complete portions of the work.

Consumers also conducts routine inspections and commissioned studies investigating the overall conditions of the facilities. Although not comprehensive, the assessments indicate the assets are in 'fair' condition but recognizes the current operations as run-of-river is inconsistent with the original peaking designs conceding efficiency and potential generation revenue. The combination of aging assets, increasing regulatory requirements which have resulted in potentially costly upgrades to some of the Project's spillways, system operations, and expected spend on necessary maintenance to keep the plants operating has raised the question of how to extract the best value out of these assets.

To achieve this goal, Consumers hired WSP USA, Inc. (WSP) to prepare the 2023 Hydropower Roadmap (Roadmap) for the 13 hydroelectric dam sites which reviewed Consumers' provided facility reports and analyzed different outcome scenarios and characterized how to achieve them. This Roadmap analyzed six scenarios that included two for relicensing, three for surrendering the license, and one to investigate divesting. Within this pursuit, an additional goal of developing an economic model as a tool to rank the potential outcomes was later added. This report details costs and considerations prepared for 2 of the 13 hydropower facilities located along the Manistee River system, including Hodenpyl Dam in Wexford County, and Tippy Dam in Manistee County.

The Manistee River system is in northwestern Michigan and incorporates 11 counties including Manistee, Wexford, Mason, Lake, Osceola, Grand Traverse, Missaukee, Kalkaska, Crawford, Otsego, and Antrim. The Manistee River watershed drains more than 1,780 square miles of land area, and over 100 tributaries flow directly into the mainstream.

The three surrendering scenarios include:

- Surrender – No-Power Generation
- Surrender and Decommission – Partial Removal
- Surrender and Decommission – Full Removal.

The objective of the conceptual decommissioning cost estimate is to identify the value of the plant's assets and estimate of the cost of utility separation, decommissioning and demolition, abatement and regulated material removal, environmental work, and restoration of the Manistee River, as well as associated project indirect costs and recommended contingencies.

2.1 HODENPYL DAM

The Hodenpyl dam (FERC Project Number P-2599), located in the Manistee River in Mesick, Wexford County, Michigan consists of two, 80-foot-high earth embankment dam sections, each with a concrete core wall and an emergency overflow spillway at the north end of the north embankment dam. The reservoir, with a normal surface area of 1,798 acres at elevation 809.0 feet (U.S. Geological Survey [USGS] datum), has a gross storage of 39,684 acre-feet.

Additionally, the dam includes a concrete and masonry powerhouse containing two generating units with a total installed capacity of 13,884 kW, and a 157-foot-long concrete apron with retaining walls in the tailrace. The powerhouse also contains two spill tubes used primarily as the service spillway.

2.2 TIPPY DAM

The Tippy dam (FERC Project Number P-2580), located in the Manistee River in Brethren, Manistee County, Michigan consists of two, 83-foot-high earth embankment dam sections. The dam includes an 83-foot-high concrete service spillway with four steel radial gates and a concrete-lined discharge channel extending approximately 240 feet downstream that includes a 24-foot-high concrete weir approximately 85 feet downstream of the radial gates.

Additionally, the dam includes a reservoir with a normal surface area of 1,330 acres at 687.4 feet (USGS datum) with a gross storage of 27,620 acre-feet, a concrete and concrete-and-masonry powerhouse containing three generating units with a total installed capacity of 14,255 kilowatts (kW), and a 170-foot-long concrete-lined tailrace with retaining walls and downstream weir.

3 STUDY APPROACH

3.1 ASSUMPTIONS

WSP analyzed the costs for three scenarios involving the surrender of the hydropower facilities before the current license expires. These scenarios include 1) Surrender – No-Power Generation: 2) Surrender and Decommission – Partial Removal; and 3) Surrender and Decommission – Full removal. Detailed description of these alternatives are as follows:

Surrender – No Power Generation Operation

The no-power generation scenario evaluates surrender of the FERC license while not removing the dam structure. The powerhouse and spillway would be modified to maintain safe flows through the system while disconnecting generation equipment. The dam would remain in place and current reservoir levels would be maintained. Additional capital improvements would be required for long term compliance with dam safety regulations.

Surrender and Decommission - Partial Removal

The partial removal scenario evaluates the partial removal of the dam by reducing the earthen dam structure while fully removing the powerhouse and generation facilities. This reduction would create a sufficient breach to pass the 100-year flood through the reestablished river channel, ensuring that the incremental rise at the dam site would be less than 0.10 foot. This scenario also considers the potential to maintain some form of upstream reservoir system while developing a new weir control structure.

This structure would be designed to fall under state regulations (Natural Resources and Environmental Protection Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir and to prevent the proliferation of invasive species such as the sea lampreys. Exposed sediments and newly exposed shoreline would be stabilized and re-vegetated.

Schematics for the partial removal scenario for the reservoir reservation for each dam structure are provided in their respective appendices of A through B.

Surrender and Decommission - Full Removal

The full removal scenario evaluates the complete removal of the dam and reservoirs. The reservoirs would be drained, powerhouse/generation facilities, earthen dam, concrete spillway, tailrace and retaining structures fully removed, and the upstream channel and floodplain restored to pre-dam conditions. To minimize the transport and improve stabilization of the sediment within the reservoir, the reservoir would be drawn down in a controlled manner. Hydraulic dredging would be performed to approximate the river's original meander to allow the river to re-establish its course through the current reservoir. Contaminated sediments, if present, would be hauled off site and disposed of properly.

Schematics for the full removal scenario for the reservoir reservation for each dam structure are provided in their respective appendices of A through B.

3.2 LIMITATIONS

- Prior costs provided by Consumers for these scenarios and developed Mead & Hunt (M&H) in 2021 were used as the foundation of these estimates. Sequencing of work follows the descriptions as detailed by M&H with additional measures incorporated following removal as part of the reservoir restoration. Estimates were supplemented and expanded based on similar experiences from other applicable dam removal projects.
- Information related to sediment volumes and characterization are estimated and assumed based on watershed research for potential hazardous contamination. As no data is available at this time, there is significant risk associated with the uncertainty to the volumes and level of contamination for management. Unless

documentation of known hazardous spills were identified for the watershed, it was considered as a mix of non-contaminated and contaminated non-hazardous sediments for removal and disposal, as detailed herein. Sediment investigations would occur after a decision to surrender and decommission were approved.

- These estimates are based on Q4 2022 dollars at the time of preparation.
- Cost estimates, by nature, are as best as the information available at the time of preparation. Estimates should be reconsidered and updated as new information is obtained and as market conditions change.
- Additional assumptions and limitations considered for each cost item to derive the presented unit pricing and quantity are detailed herein.

4 COST ESTIMATE SUMMARY

4.1 CLASS ESTIMATES

Although hydropower costs are highly site-specific with many factors contributing to cost uncertainty, costs accuracy is generally assumed to increase as project development nears completion. As such construction stage cost estimates are necessarily considered the most accurate and are quantitatively defined as such by Association for the Advancement of Cost Engineering (AACE). The level of information or considerations prepared for this independent evaluation, with limitations, would be considered as Class 5 estimate per AACE.

4.1.1 CLASS 5 ESTIMATE

This is known as the rough order of magnitude (ROM) estimate. It is used for the initial screening projects for capital expenditure planning. Since several projects are initially available, estimating each would require a tremendous amount of time and effort. Given the limited preparation, ballpark figures are usually accepted to make business plan projections. Class 5 estimates are drawn from limited information which is about 0 to 2% of the project definition. The information may be nothing more than a basic description of the plant or process, capacity, and location. That is why its accuracy ranges -50% on the low side and +100%on the high side.

Class 5 cost estimate accuracy range: -50% to +100%

Stochastic cost estimating methods are used for obtaining a Class 5 estimate. Examples of these are cost/capacity curves, rule of six-tenths, Lang factor method, scale of operation factors, and cost indices. These techniques use parametric cost estimation methods to deduce the total cost of a given project.

4.2 COST ESTIMATE SUMMARIES

Costs for each surrender scenario were calculated for (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. Detailed descriptions for each item under each scenario are provided below.

All units used in the cost estimate are U.S. Standard and all costs are in US Dollars (4th Quarter 2022 levels). The conceptual decommissioning cost estimates for each scenario by dam location are included in Appendix A through B.

4.2.1 QUANTITIES AND UNIT COSTS

Quantities of pieces of equipment and/or bulk material commodities used in the cost estimates were intended to be reasonable and representative of projects of this type. Material quantities were prepared by M&H in 2021 for categorial items included within their estimate. As appropriate, WSP simplified unit measurements and unit pricing for subject activities. For additional activity items incorporated by WSP, quantities were estimated from the schematic renderings prepared for each site and included within Appendix A through B, as detailed below. Upon determining corrective unit quantities and unit costs, cost components for each activity were determined by the multiplication of the unit quantity by unit cost, rounded to the nearest whole dollar.

4.2.2 UNCERTAINTY AREAS

This estimate will be based on similar experiences from other projects. Therefore, some specific information about each site is unknown. Additional studies would be needed to determine physical and chemical characteristics of soils and

sediments, potential costs required to manage and dispose of potentially contaminated sediments upstream of the structures, type of vegetation and presence of non-native species, archaeological resources and historic structures, hydrology and hydraulic characteristics, as well as ecology and biology upstream and downstream of the structures.

4.2.3 HODENPYL DAM COST ESTIMATE ACTIVITIES

Table 4.1 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.1 Hodenpyl Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Replace 46/138-kV Substation		X	X
	Remove Power Lines Between Powerhouse and Substation		X	X
	Leave Powerhouse Intact	X		
Decommissioning and Demolition	Remove Security Fencing		X	X
	Remove Plant Access Road		X	X
	Remove Septic Tank / Drain Field		X	X
	Remove Downstream Soil Nail Wall			X

	Construction Management, Biological Monitoring and O&M	X	X	X
Contingency	Cost Contingency	X	X	X

Replace 46/138kV Substation

Lump sum cost was taken from the M&H cost estimate for replacement of the 46/138-kV Hodenpyl substation. The partial and full removal options assume that the Hodenpyl Plant would be replaced to keeping the electrical requirements intact.

Remove Power Lines Between Powerhouse and Substation

Linear footage and price per linear foot was taken from the M&H. Work includes removal of the power lines between the powerhouse and substation as part of the partial and full removal scenarios.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H cost estimate. The powerhouse structure would be left in place under the non-power operation option. Once the electrical generating equipment had been removed, water intake into the power plant would be plugged with concrete and the power conduits beneath the powerhouse would be filled with sand.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary. Work includes approximately 635-station of the access road to be removed with the remaining left to provide access to the 138-kV corridor.

Remove Septic Tank/Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Downstream Soil Nail Wall

Cubic yard unit price was taken from the M&H estimate. For full removal this will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 35 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove or Lay-Up Equipment

Lump sum cost was taken from the M&H cost estimate. Under the non-power operation option, the turbine-generator would be disabled, and all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance would be decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons ("CFCs") and other hazardous materials routinely associated with the plant's electromechanical equipment.

Remove all Powerhouse Equipment

Lump sum cost was taken from the M&H estimate. Under the partial and full removal options, all the plant electromechanical equipment, controls, protection, and station transformers would be removed from the powerhouse during its demolition and transported to an off-site disposal area.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Remove Garage

Lump sum cost was taken from the M&H estimate. Under the partial and full removal options, garage would be removed during decommissioning and transported to an off-site disposal area.

Demolish and Remove Concrete/Masonry

Cubic yard unit price was taken from the M&H estimate. Under the partial and full removal options, concrete/masonry would be removed during decommissioning and transported to an off-site disposal area.

Remove Trash Racks

Provided as a price per ton was taken from the M&H estimate. Under the partial and full removal options, trash racks would be removed during decommissioning and transported to an off-site disposal area.

Remove Valves

Provided as a price per ton was taken from the M&H estimate. Under the partial and full removal options, valves would be removed during decommissioning and transported to an off-site disposal area.

Remove Sheet Piling

Provided as a cost per square foot was taken from the M&H estimate. Under the partial and full removal options, sheet piling would be removed from during decommissioning and transported to an off-site disposal area.

Remove Intake Wall/Walkway

Provided as a price per ton was taken from the M&H estimate. Under the partial and full removal options, wall/walkways would be removed during decommissioning and transported to an off-site disposal area.

Remove Hoist Rail

Provided as a price per ton was taken from the M&H estimate. Under the partial and full removal options, hoist rails would be removed during decommissioning and transported to an off-site disposal area.

Remove Gates

Provided as a price per ton was taken from the M&H estimate. Under the partial and full removal options, gates would be removed during decommissioning and transported to an off-site disposal area.

Drain 1,798-Acre Reservoir

Lump sum cost provided was taken from the M&H cost estimate. Under the partial and complete removal options, the reservoir would be drained in a controlled manner through the powerhouse during removal of the powerhouse structure, intake tower, penstocks, and a section of the embankment dam. The removal will be staged and the effect of lowering the reservoir on project wetlands will be monitored monthly throughout the process. Once these elements of the project have been removed, the embankment dam would be breached sufficiently to allow the 100-year-flood flow to pass through the natural river channel located to the right of the powerhouse structure.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Provided as a cost per cubic yard was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall - Sheet Piling Removal

Provided as a cost per square foot was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for sheet pile cutoff with all material disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal, a 300-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Grading & Surface Preparation/Amendments

WSP added cost for grading and surface preparation/amendments for newly exposed sediments within the reservoir for floodplain restoration.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Apply Erosion Control Measures - Silt Fence

Price per linear foot and unit quantity was taken from the M&H estimate. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 15% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the Manistee River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 85% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the Manistee River, as well as both banks for all tributary lengths.

Channel Creation - Riffle Section at Downstream Tie In

This item involves the placement of river rock along a portion at the downstream limits of work for the riffle bed reconstruction. It is assumed that the riffle section will be 300-feet-wide, 1,000-feet-long, and 2-feet-deep for the full removal while only 500-feet-long for the partial removal. The river rock will be strategically placed to enhance the stability and functionality of the riffle, promoting better water flow and habitat conditions.

Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 95-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 9-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot-drop and 3-foot-footer) and 4-foot-width.

Owner's Cost

An owner's cost of 15% of the construction subtotal was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $452,241 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring and O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal were applied. These costs may be variable as the design develops and permit stipulations are identified.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.4 TIPPY DAM COST ESTIMATE ACTIVITIES

Table 4.2 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.2 Tippy Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL

Project Indirect	Baseline Studies, Engineering and Permitting	X	X	X
	Construction Management, Biological Monitoring and O&M	X	X	X
Contingency	Cost Contingency	X	X	X

Remove Overhead Lines Between Powerhouse and MTB No. 2

Linear footage and price per linear foot was taken from the M&H. Work includes removal of the overhead lines between the powerhouse and MTB No. 2 as part of the partial and full removal scenarios.

Move Distribution Line from Plant Bus

Linear footage and price per linear foot was taken from the M&H. Under the partial and full removal, the distribution lines would no longer be required and removed entirely. Under the no-power generation scenario, electricity for the spillway operations would be required and services left in place to the plant for operation and maintenance of the plant.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H estimate. Scope of work outlined by M&H for the no-power generation scenario includes addressing public safety and environmental concerns to leave the powerhouse in place. This includes installation of precast concrete stoplogs in the power intake and draft tube exits to isolate the powerhouse water conduits following electromechanical equipment removal. Once isolated from reservoir and tailrace, the power conduits would be filled with sand up to the generator gallery floor.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Office Building

Lump sum cost was taken from the M&H estimate. The onsite office building will be demolished and disposed of offsite for all three scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary. Work includes approximately 600 feet of the access road to be removed with the remaining left to provide access to the relocated overhead distribution line.

Remove Septic Tank / Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 11 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove All Powerhouse Equipment

Lump sum cost was taken from the M&H estimate. For the partial and full removal scenarios, all the powerhouse equipment related to the generation of electricity would be decommissioned and disposed of offsite.

Remove Precast Stoplogs

Cubic yard unit price was taken from the M&H estimate. For the partial and full removal scenarios, all the precast stoplogs related to the generation of electricity would be decommissioned and disposed of offsite.

Demolish and Remove Concrete/Masonry

Cubic yard unit price was taken from the M&H estimate. Under the partial and full removal options, concrete/masonry would be removed during decommissioning and transported to an off-site disposal area.

Remove Trash Racks

Provided as a price per ton was taken from the M&H estimate. Under the partial and full removal options, trash racks would be removed during decommissioning and transported to an off-site disposal area.

Excavate / Dispose Earth Fill

Cubic yard unit price was taken from the M&H estimate. Under the partial and full removal options, earth fill would be removed during decommissioning and transported to an off-site disposal area.

Remove Downstream Sheet Pile Weir

Provided as a cost per square foot was taken from the M&H estimate. Under the partial and full removal options, sheet pile weir would be removed during decommissioning and transported to an off-site disposal area.

Remove or Lay-Up Equipment

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the turbine-generator with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Remove Gates

Provided as a price per ton was taken from the M&H estimate. Under the partial and full removal options, gates would be removed during decommissioning and transported to an off-site disposal area.

Demolish and Remove Concrete

Cubic yard unit price was taken from the M&H estimate. Under the partial and full removal options, concrete would be removed during decommissioning and transported to an off-site disposal area.

Remove Gates

Provided as a price per ton was taken from the M&H estimate. Under the partial and full removal options, gates would be removed during decommissioning and transported to an off-site disposal area.

Drain 1,330-Acre Reservoir

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate includes draining the reservoir in a controlled manner through the powerhouse and spillway structure as they are demolished and removed in a staged process. The staged removal of the spillway would require that a steel sheet pile, gravel-filled cellular cofferdam with removable stoplogs, be placed upstream of the spillway. This cofferdam would allow the demolition of the entire spillway while regulating the diversion of river flows through the powerhouse structure. Once the reservoir has been lowered to the spillway foundation slab, the cofferdam would be removed to allow flows to be diverted through the previous spillway area to the natural river channel, and the remaining powerhouse bays, guide walls, and aprons would be removed. Once the powerhouse and spillway structures have been removed, the removal of the embankment dam would be completed. WSP price considers cofferdam and diversion for both scenarios and concrete stoplogs.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. The earth dams would be completely removed under the full removal scenario. It is assumed excavated earth material will stay onsite to reflect the unit price prepared by M&H.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Cubic yard unit price was taken from the M&H estimate. As part of the earth dam removal, the concrete core wall will be demolished and disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall - Sheet Piling Removal

Square foot unit price was taken from the M&H estimate. This activity accounts for the sheet pile cutoff, in which all of the sheet pile wall as part of the core wall will be removed and disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal, a 200-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal scenarios, this work includes additional hydraulic dredging of the reservoir area beyond the 200-foot-wide pilot channel during the drawdown process to restore the floodplain characteristics of the Manistee River. Unit quantities derived from M&H estimate and does not take into consideration additional volume removed for contaminated non-hazardous material. All material is considered non-contaminated and reused onsite. Following removal of the dam.

For the partial removal scenario, WSP considered an 85% quantity reduction in volume removed based on installation of a replacement weir system and upstream reservoir design to maintain a smaller impounded water level.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Grading & Surface Preparation / Amendments

WSP added cost for grading and surface preparation / amendments onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Channel Creation - Riffle Section at Downstream Tie In

WSP derived cost for performing additional channel restoration for a length immediately at and above the dam that includes imported rock. For the partial removal, a 300-foot-length is considered upstream of the revised water impounded area. For the full removal, a 600-foot-length is considered for the dam footprint extending to the same termination point as the partial removal.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Apply Erosion Control Measures - Silt Fence

Price per linear foot and unit quantity was taken from the M&H estimate. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 15% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the Manistee River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 85% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the Manistee River, as well as both banks for all tributary lengths.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot-drop and 3-foot-footer) and 4-foot-width.

Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 26-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 6-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Owner's Cost

An owner’s cost of 15% of the construction subtotal was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $373,419 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring and O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal were applied. These costs may be variable as the design develops and permit stipulations are identified.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.5 COST ESTIMATE RESULTS SUMMARY

The full conceptual decommissioning cost estimate for each dam site and scenario are provided in Appendix A through B. Tables 4.4 to Table 4.5 provide a summary of total cost by category for Hodenpyl and Tippy dams, respectively.

Table 4.3 Hodenpyl Dam Cost Estimate Results Summary

DESCRIPTION	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	$94,463	$3,210,577	$3,210,577
Decommissioning and Demolition	$176,946	$38,686,545	$61,514,165
Salvage	-	$(57,430)	$(57,430)
Environmental and Restoration	$3,950,000	$62,413,804	$85,135,883
Subtotal	**$4,221,409**	**$104,253,496**	**$149,803,195**
Project Indirect	$2,060,344	$21,771,968	$30,709,656
Contingency Cost	$422,141	$10,425,350	$14,980,320
Total Project Cost	**$6,703,894**	**$136,450,814**	**$195,493,171**

Table 4.4 Tippy Dam Cost Estimate Results Summary

DESCRIPTION	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	$247,575	$220,139	$220,100
Decommissioning and Demolition	$271,578	$28,148,861	$29,773,425
Environmental and Restoration	$3,450,000	$40,208,513	$43,761,145
Subtotal	**$3,969,153**	**$68,577,513**	**$73,754,670**
Project Indirect	$1,909,629	$14,458,391	$15,119,709
Contingency Cost	$396,916	$6,857,752	$7,375,467
Total Project Cost	**$6,275,698**	**$89,893,656**	**$96,249,846**

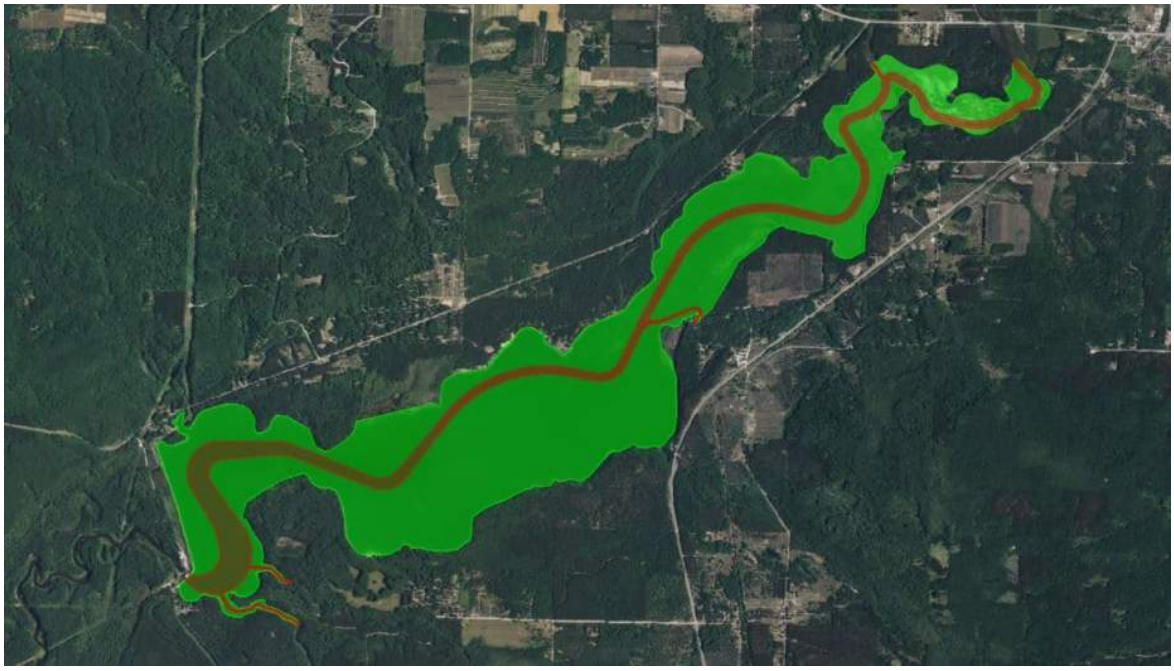
APPENDIX

A HODENPYL DAM HYDROELECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

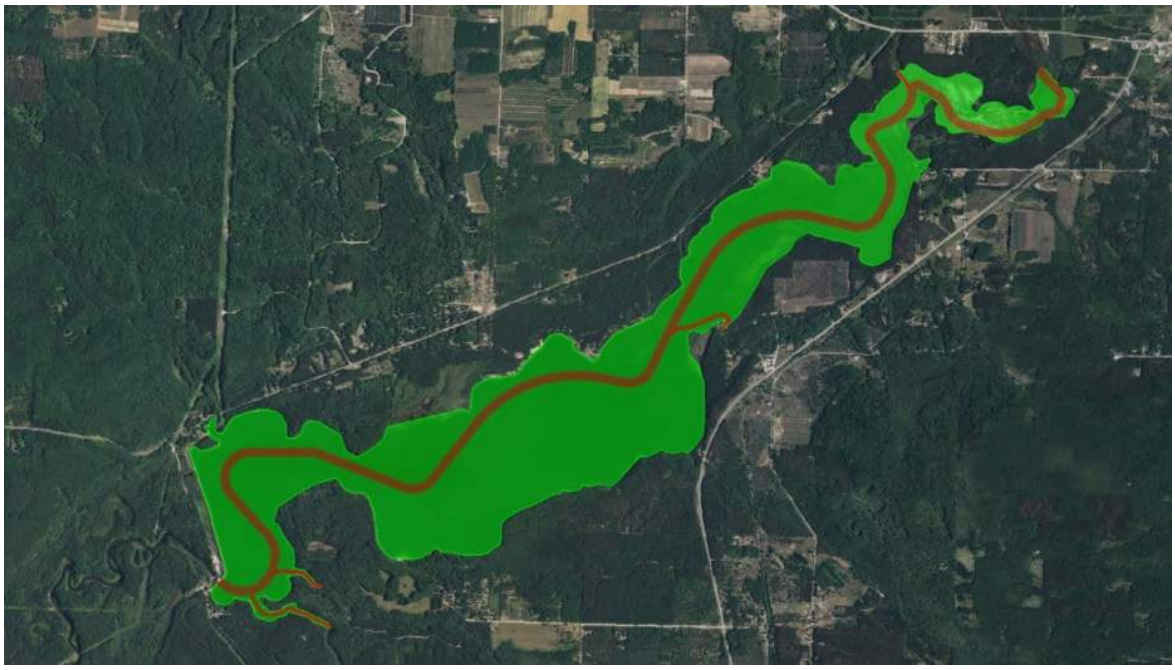


A-1 HODENPYL DAM SITE SUMMARY

Site Characteristics

- Two, 80-foot-high earth embankment dam sections, each with a concrete core wall.
- An emergency overflow spillway at the north end of the north embankment dam.
- A reservoir with a normal surface area of 1,798 acres at elevation 809.0 feet (USGS datum) and a gross storage of 39,684 acre-feet.
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 13,884 kW.
- A 157-foot-long concrete tailrace with retaining walls.
- Associated appurtenant structures

Surrendering – Partial Decommissioning



- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
- Cons/Risks
  - Section 7 of the Endangered Species Act requires consultation with Fish & Wildlife Service, which may require other associated studies will be required because the Manistee River downstream of Tippy Dam is designated as a National Wild and Scenic River.
  - Features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Water quality (temperature and potentially dissolved oxygen (DO)) may still be out of compliance for cold water fisheries under License Article 405.
  - May also still cause sediment transport issues.
  - Public disapproval of this option due to its socioeconomic and recreational impact.
  - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its

failure may cause damage limited to agriculture, uninhabited buildings, structures, or township or county roads, where environmental degradation would be minimal, and where danger to individuals is slight or nonexistent. This opinion is based on the following considerations:

- Manistee River trail suspension bridge approximately 2,200 FT downstream of dam
- Transmission line monopoles on either side of bank 2,500 FT downstream of dam (likely at high enough elevation to be out of damage risk area)
- Upper River Road boat launch along right bank approximately 3,400 FT downstream of dam
- N Coates Highway bridge >6 miles downstream of dam
- Upper River Road runs along right bank, but no structures nor inhabited homes on either side of downstream banks.
-

Surrendering – Full Decommissioning

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Fish passage opened without installing a fish passage system (discontinuation of MDNR stocking).
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.

    - Habitat can be restored along the entire footprint of the dam.
  - Eliminates issues of water quality (temperature and potentially DO).
    - Recent letters filed with FERC allege the discharge from Hodenpyl Dam violates the 1992 Federal Energy Regulatory Commissions Settlement Agreement for temperature. Options to lower water temperatures are recommended to improve natural reproduction and recruitment of salmon populations, improve water quality, and reduce reliance on hatchery stocking. Currently the system is not self-sustaining as the Hodenpyl Dam is out of compliance more than half the time during June through September and 70% of the time over the entire year. Sections of the river upstream of Hodenpyl Dam have been evaluated for potential Arctic grayling reintroduction, current dam operation would negatively impact that.
  - Eliminates sediment transport issues
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Public disapproval of this option due to its socioeconomic and recreational impact.

A-2 HODENPYL DAM NO-POWER GENERATION SCENARIO CONCEPTUAL ESTIMATE

Consumers Energy
Hodenpyl Dam
Decommissioning Cost Evaluation - Non-Power Operation

Category	Cost Activity	WSP Unit Cost	Unit	Quantity	WSP Opinion of Cost
Utility Separation	Leave powerhouse intact	$ 94,463.00	LS	1	$ 94,463
Decommissioning and Demolition	Remove or lay up equipment	$ 88,384.00	LS	1	$ 88,384
	Modify spillway to maintain flow/pond level	$ 56.77	CY	1560	$ 88,562
Environmental and Restoration	Installation of fish passage	$ 50,000.00	VLF	79	$ 3,950,000
	Subtotal				**$ 4,221,409**

	Remove accumulated non-contaminated sediments	$ 7.09	CY	3741028.75	$ 26,523,894
	Mobilization/demobilization	$ 236,154.00	LS	1	$ 236,154
Environmental and Restoration	Reuse(grading) of non-contaminated excavated and dredged material	$ 8.00	CY	4085789.75	$ 32,686,318
	Grading and surface preparation/amendments	$ 6,700.00	ACRE	1514	$ 10,143,800
	Seed former reservoir bottom	$ 3,100.00	ACRE	1514	$ 4,693,400
	Plant former reservoir bottom	$ 3,072.00	ACRE	1514	$ 4,651,008
	Apply Erosion Control Measures: Silt Fence	$ 5.00	LF	28000	$ 140,000
	Apply Erosion Control Measures: Rip Rap Protection	$ 150.00	CY	5000	$ 750,000
	Bank Stabilization - Hard Structure	$ 333.33	LF	12896	$ 4,298,624
	Bank Stabilization - Live stakes and Jute Matting	$ 54.53	LF	51584	$ 2,812,876
	Channel creation - riffle section at downstream tie-in	$ 150.00	CY	5185.185185	$ 777,778
	Fish passage	$ 50,000.00	VLF	9	$ 450,000
	Concrete weir installation	$ 5,050.00	LF	200	$ 1,010,000
Salvage	Salvage value	$ (57,430.00)	LS	1	$ (57,430)
	Subtotal				**$ 104,253,496**
Project Indirect	Owner's Cost (15%)				$ 15,638,025
	Baseline Studies, Engineering and Permitting				$ 4,048,873
	Construction Management, Biological Monitoring & O&M				$ 2,085,070
Contingency Cost	Contingency (10%)				$ 10,425,350
Total Project Costs	**Total**				**$ 136,450,814**

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database.

4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

A-4 HODENPYL DAM FULL REMOVAL SCENARIO CONCEPTUAL ESTIMATE

	Bank Stabilization - Hard Structure	LF	$ 333.33	18243	$ 6,080,873
	Bank Stabilization - Live stakes and Jute Matting	LF	$ 54.53	72971	$ 3,979,120
	Channel creation - riffle section at downstream tie-in	CY	$ 150.00	14815	$ 2,222,250
Salvage	Salvage value	LS	$ (57,430)	1	$ (57,430)
	Subtotal				**$ 149,803,195**
Project Indirect	Owner's Cost (15%)				$ 22,470,480
	Baseline Studies, Engineering and Permitting				$ 5,243,112
	Construction Management, Biological Monitoring & O&M				$ 2,996,064
Contingency Cost	Contingency (10%)				$ 14,980,320
Total Project Costs	**Total**				**$ 195,493,171**

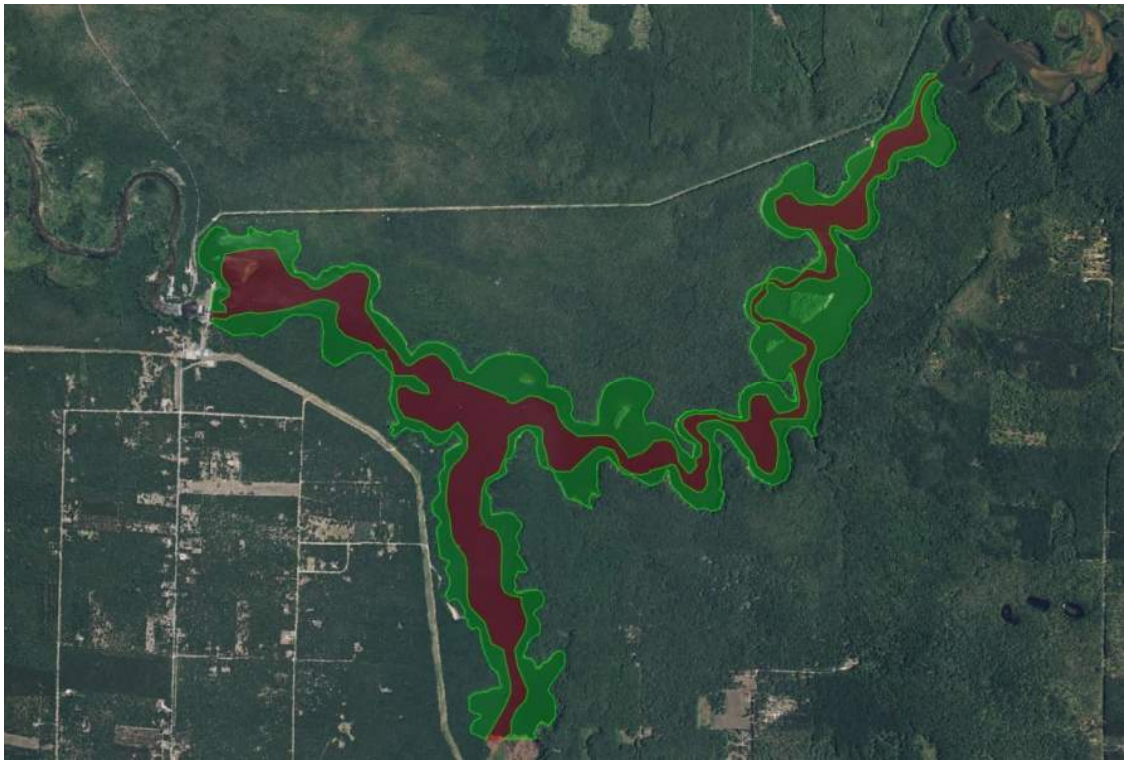
Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.

B TIPPY DAM HYDROLECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

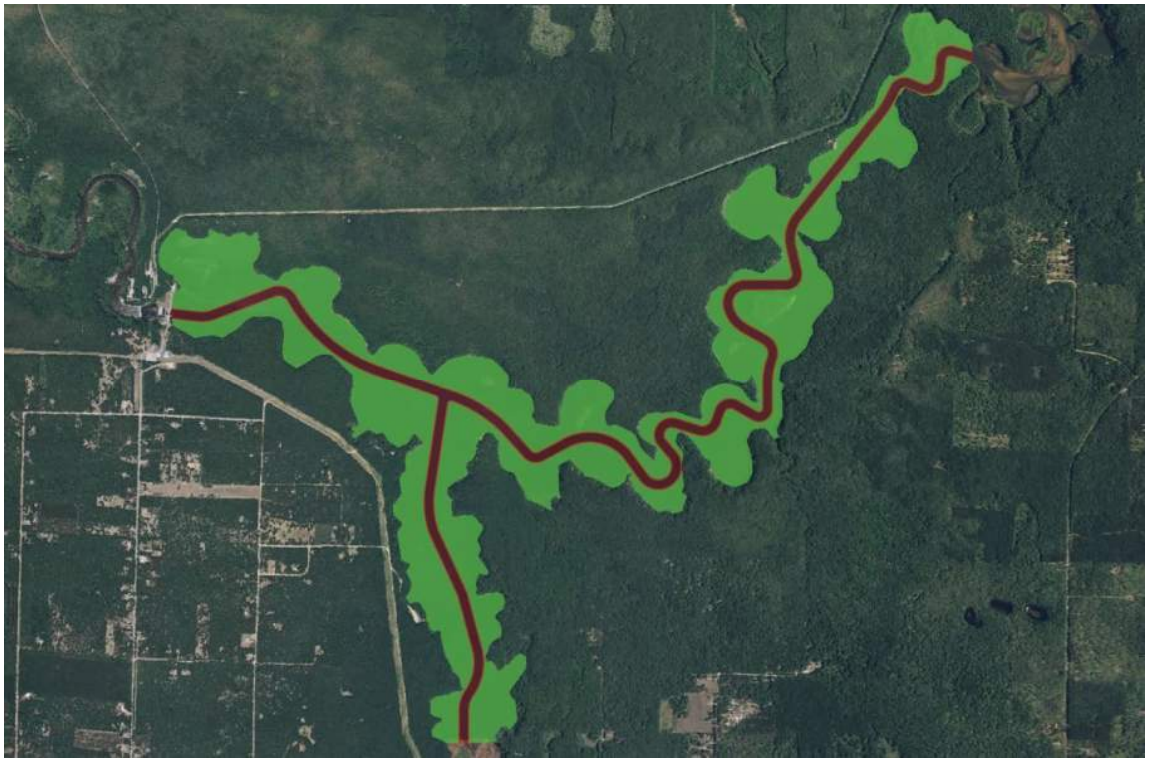


B-1 TIPPY DAM SITE SUMMARY

Site Characteristics

- Two, 83-foot-high earth embankment dam sections, each with a concrete core wall.
- An 83-foot-high concrete spillway with four steel radial gates and a concrete-lined discharge channel extending approximately 240 feet downstream that includes a 24-foot-high concrete weir approximately 85 feet downstream of the radial gates.
- A reservoir with a normal surface area of 1,330 acres at elevation 687.4 feet (U.S. Geological Survey [USGS] datum) and a gross storage of 27,620 acre-feet.
- A concrete and masonry powerhouse containing three generating units with a total installed capacity of 14,255 kilowatts (kW).
- A 170-foot-long concrete-lined tailrace with retaining walls and downstream weir.
- Associated appurtenant structures.

Surrendering – Partial Decommissioning



- Pros
  - The Tippy Dam is not currently meeting Article 405 discharge water temperature standards and has been determined to not be self-sustaining

- Cons/Risks
  - Tippy Dam is a barrier to invasive species traveling upstream from Lake Michigan.
  - Water quality (temperature and potentially dissolved oxygen (DO)) may still be out of compliance for cold water fisheries under License Article 405.
  - Tippy Dam has been identified as the only place in the upper Midwest where little brown bat populations have not been affected by White Nose Syndrome. It has not yet been determined why this is but any changes to the environment are highly discouraged. Researchers consider the site a valuable opportunity to determine why bat populations are protected there and studying it could lead to figuring out how to replicate conditions in areas that are affected. The powerhouse is a regionally important hibernacula to an estimated 10,000 little brown bats.
  - Fish passage system should be designed with consideration to allow desirable species (Lake Sturgeon) and prevent non-desirable species (Sea Lamprey) from upstream migration.
  - Tippy Dam is part of the Manistee River which is designated as a National Wild and Scenic River. A section 7 of the Endangered Species Act analysis is required

for any changes to ensure the free-flow, water quality, and Outstanding Remarkable Values of the rivers are maintained.

- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:
  - Tippy Dam Recreation Area < 500 FT downstream of dam
  - Tippy Dam Public Fishing Access 1,700 FT downstream of dam
  - 1 inhabited residential home >5 miles downstream of dam
  - N High Bridge Road Bridge >5.5 miles downstream of dam
  - Dilling Road runs along right bank for about first 4,000 FT downstream of dam

Surrendering – Full Decommissioning

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
  - Habitat can be restored along the entire footprint of the dam.
  - Eliminates issues of water quality (temperature and potentially DO).
  - Recent letters filed with FERC allege the discharge from Hodenpyl Dam violates the 1992 Federal Energy Regulatory Commissions Settlement Agreement for temperature. Options to lower water temperatures are recommended to improve natural reproduction and recruitment of salmon populations, improve water quality, and reduce reliance on hatchery stocking. Currently the system is not self-sustaining as the Tippy Dam is out of compliance more than half the time during June through September and 70% of the time over the entire year. Sections of the river upstream of Hodenpyl Dam have been evaluated for potential Arctic grayling reintroduction, current dam operation would negatively impact that.
  - Eliminates sediment transport issues

- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Public disapproval of this option due to its socioeconomic and recreational impact.
  - Consideration of a barrier system to prevent upstream migration of invasive species (sea lamprey and round goby)

	Concrete weir installation	LF	$ 5,050.00	200	$ 1,010,000
	Fish Passage	VLF	$ 50,000.00	9	$ 450,000
	Bank Stabilization - Hard Structure	LF	$ 333.33	11908	$ 3,969,161
	Bank Stabilization - Live stakes and Jute Matting	LF	$ 54.53	47630	$ 2,597,286
	Subtotal				**$68,577,513**
Project Indirect	Owners Cost (15%)				$10,286,627
	Engineering and Permitting				$2,800,213
	Construction Management & Biological Monitoring				$1,371,551
Contingency Cost	Contingency (10%)				$6,857,752
Total Project Costs	**Total**				**$89,893,656**

Notes:

1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database. Additional cost assumptions stated above.

4. Partial removal includes installation of a 6' weir to preserve an impounded section of reservoir.

1 EXECUTIVE SUMMARY

Consumers Energy Company (Consumers) owns and operates 13 river hydro dam facilities located on the Muskegon, Manistee, Grand, Au Sable, and Kalamazoo Rivers. The average age of these assets is 106 years old and much of each site is original construction and equipment. Consumers would need to start relicensing 11 of the 13 projects with filings signaling their intentions no later than June 30, 2029, meaning a plan for the assets should be in place within the next few years to prepare for filing with Federal Energy Regulatory Commission (FERC). In addition, FERC has recently updated their Part 12 inspection requirements. The revised inspections put more emphasis on Potential Failure Mode Analysis, updated Probable Maximum Flood, and Semi-Quantitative Risk Analysis level 2 effort for each site. These enhanced regulations require subject matter experts and facilitators to complete portions of the work.

Consumers also conducts routine inspections and commissioned studies investigating the overall conditions of the facilities. Although not comprehensive, the assessments indicate the assets are in 'fair' condition but recognizes the current operations as run-of-river is inconsistent with the original peaking designs conceding efficiency and potential generation revenue. The combination of aging assets, increasing regulatory requirements which have resulted in potentially costly upgrades to some of the Project's spillways, system operations, and expected spend on necessary maintenance to keep the plants operating has raised the question of how to extract the best value out of these assets.

To achieve this goal, Consumers hired WSP USA, Inc. (WSP) to prepare the 2023 Hydropower Roadmap (Roadmap) for the 13 hydroelectric dam sites which reviewed Consumers' provided facility reports and analyzed different outcome scenarios and characterized how to achieve them. This Roadmap analyzed six scenarios that included two for relicensing, three for surrendering the license, and one to investigate divesting. Within this pursuit, an additional goal of developing an economic model as a tool to rank the potential outcomes was later added.

This report details the surrendering considerations and pricing considered in the roadmap for 3 of the 13 hydropower facilities located within the Muskegon River Watershed, including the including Hardy and Croton Dams in Newago County, and Rogers Dam in Mecosta County.

Three surrender scenarios with specific assumptions were considered in preparing the cost estimates for each surrender option:

1. Surrender– No-Power Generation: The no-power generation scenario evaluates surrender of the FERC license while not removing the dam structure. The powerhouse and spillway would be modified to maintain safe flows through the system while disconnecting generation equipment. The dam would remain in place and current reservoir levels would be maintained. Additional capital improvements would be required for long term compliance with dam safety regulations.
2. Surrender and Decommission – Partial Removal: The partial removal scenario evaluates partial removal of the dam via reduction of the earthen dam structure with full removal of the powerhouse and generation facilities. This scenario evaluates the potential to leave some form of upstream reservoir system while developing a new weir control structure. This structure would be designed to fall under state regulations (Natural Resources and Environmental Protection Act (NREPA), Part 315, Dam Safety), not FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir and to prevent the proliferation of invasive species such as the sea lampreys.
3. Surrender and Decommission - Full Removal: The full removal scenario evaluates the complete removal of the dam and reservoirs. The reservoirs would be drained, powerhouse/generation facilities and earthen dam structures fully removed, and the upstream channel and floodplain restored to pre-dam conditions.

For each facility and scenario, a class 5 cost estimate was prepared in Q4 2022 dollars, identifying and quantifying the value of the plant's assets and estimate of the cost of utility separation, decommissioning and demolition, abatement and regulated material removal, environmental and restoration work of the Muskegon River, as well as associated project indirect costs and recommended contingency. Schematics utilized for the evaluation of the Surrender and Decommission – Partial and Full Removal for how the reservoir may be reshaped in the decommissioning restoration are presented. Additional assumptions and limitations by site are presented herein.

2 INTRODUCTION

Consumers Energy Company (Consumers) owns and operates 13 river hydro dam facilities located on the Muskegon, Manistee, Grand, Au Sable, and Kalamazoo Rivers. The average age of these assets is 106 years old and much of each site is original construction and equipment. Consumers would need to start relicensing 11 of the 13 projects with filings signaling their intentions no later than June 30, 2029, meaning a plan for the assets should be in place within the next few years to prepare for filing with Federal Energy Regulatory Commission (FERC). In addition, FERC has recently updated their Part 12 inspection requirements. The revised inspections put more emphasis on Potential Failure Mode Analysis, updated Probable Maximum Flood, and Semi-Quantitative Risk Analysis level 2 effort for each site. These enhanced regulations require subject matter experts and facilitators to complete portions of the work.

Consumers also conducts routine inspections and commissioned studies investigating the overall conditions of the facilities. Although not comprehensive, the assessments indicate the assets are in 'fair' condition but recognizes the current operations as run-of-river is inconsistent with the original peaking designs conceding efficiency and potential generation revenue. The combination of aging assets, increasing regulatory requirements which have resulted in potentially costly upgrades to some of the Project's spillways, system operations, and expected spend on necessary maintenance to keep the plants operating has raised the question of how to extract the best value out of these assets.

To achieve this goal, Consumers hired WSP USA, Inc. (WSP) to prepare the 2023 Hydropower Roadmap (Roadmap) for the 13 hydroelectric dam sites which reviewed Consumers' provided facility reports and analyzed different outcome scenarios and characterized how to achieve them. This Roadmap analyzed six scenarios that included two for relicensing, three for surrendering the license, and one to investigate divesting. Within this pursuit, an additional goal of developing an economic model as a tool to rank the potential outcomes was later added. This report details costs and considerations prepared for 3 of the 13 hydropower facilities located along the Muskegon River system, including Hardy and Croton Dams in Newago County, and Rogers Dam in Mecosta County.

The Muskegon River system is the second largest river system in Michigan. It is in north-central Michigan and incorporates 9 counties including Wexford, Roscommon, Missaukee, Clara, Osceola, Mecosta, Montcalm, Newaygo, and Muskegon. The Muskegon River watershed drains more than 2,700 square miles of land area, and approximately 94 tributaries flow directly into the mainstream.

The three surrendering scenarios include:

- Surrender – No-Power Generation
- Surrender and Decommission – Partial Removal
- Surrender and Decommission – Full Removal.

The objective of the conceptual decommissioning cost estimate is to identify the value of the plant's assets and estimate of the cost of utility separation, decommissioning and demolition, abatement and regulated material removal, environmental work, and restoration of the Muskegon River, as well as associated project indirect costs and recommended contingencies.

2.1 HARDY DAM

The Hardy dam (FERC Project Number 2452), located in the Muskegon River in Big Prairie Township, Newaygo County, Michigan consists of a 114-foot-high, 2,600-foot-long earth embankment dam section with a concrete core wall, a service spillway integral to the powerhouse, and a 600-foot-long fixed-crest auxiliary spillway with a concrete-lined (for the upper 880 feet) discharge channel. The reservoir, with a normal surface area of 3,902 acres at elevation 822.0 feet (U.S. Geological Survey [USGS] datum), has a gross storage of 134,973 acre-feet with depths varying 70-100 feet within the channel that meanders through the impoundment.

Additionally, the dam includes a steel-framed concrete-and-masonry intake structure with upper and lower intake openings, three concrete penstocks to convey water from the lower intake opening to the intake tower, three steel-lined concrete penstocks to convey water from the intake tower to the powerhouse that includes a service spillway, a steel-framed concrete-and-masonry powerhouse containing three generating units with a total installed capacity of 29,229 kW, and a 200-foot-long concrete apron with retaining walls in the tailrace.

2.2 ROGERS DAM

The Rogers dam (FERC Project Number 2451), located in the Muskegon River in Mecosta Township, Mecosta County, Michigan consists of 3 earth embankment dam sections (one section 48-feet-high and two sections 40-feet-high), each with a concrete core wall and totaling 600-feet-long. The dam includes a 40-foot-high, 156-foot-long concrete service spillway with six steel radial gates, a defunct log chute, and a concrete-lined discharge channel extending approximately 100 feet downstream.

Additionally, the dam includes a reservoir with a normal surface area of 449 acres at 861.6 feet (USGS datum) with a gross storage of 4,678 acre-feet, a concrete and concrete-and-masonry powerhouse containing four generating units with a total installed capacity of 5,418 kilowatts (kW), and a 20-foot-long concrete apron with retaining walls in the powerhouse tailrace.

2.3 CROTON DAM

The Croton dam (FERC Project Number 2468), located in the Muskegon River in Croton Township, Newaygo County, Michigan consists of 2 earth embankment dam sections (one section 53-feet-high and one section 19-feet-high), each with a concrete core wall. It additionally includes a 53-foot-high and 240-foot-long concrete service spillway with eight steel radial gates, an overflow weir, and a concrete-lined discharge channel extending approximately 250 feet downstream with a 7-foot-high concrete weir located approximately 53 feet downstream. The dam maintains a reservoir with a normal surface area of 1,209 acres at elevation 722.0 feet (USGS datum) with a gross storage of 21,932 acre-feet, as well as concrete-and-masonry powerhouse containing four generating units with a total installed capacity of 7,473 kW, and a 31-foot-long concrete apron with retaining walls in the tailrace.

3 STUDY APPROACH

3.1 ASSUMPTIONS

WSP analyzed the costs for three scenarios involving the surrender of the hydropower facilities before the current license expires. These scenarios include 1) Surrender – No-Power Generation: 2) Surrender and Decommission – Partial Removal; and 3) Surrender and Decommission – Full removal. Detailed description of these alternatives are as follows:

Surrender – No Power Generation Operation

The no-power generation scenario evaluates surrender of the FERC license while not removing the dam structure. The powerhouse and spillway would be modified to maintain safe flows through the system while disconnecting generation equipment. The dam would remain in place and current reservoir levels would be maintained. Additional capital improvements would be required for long term compliance with dam safety regulations.

Surrender and Decommission - Partial Removal

The partial removal scenario evaluates the partial removal of the dam by reducing the earthen dam structure while fully removing the powerhouse and generation facilities. This reduction would create a sufficient breach to pass the 100-year flood through the reestablished river channel, ensuring that the incremental rise at the dam site would be less than 0.10 foot. This scenario also considers the potential to maintain some form of upstream reservoir system while developing a new weir control structure.

This structure would be designed to fall under state regulations (Natural Resources and Environmental Protection Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir and to prevent the proliferation of invasive species such as the sea lampreys. Exposed sediments and newly exposed shoreline would be stabilized and re-vegetated.

Schematics for the partial removal scenario for the reservoir reservation for each dam structure are provided in their respective appendices of A through C.

Surrender and Decommission - Full Removal

The full removal scenario evaluates the complete removal of the dam and reservoirs. The reservoirs would be drained, powerhouse/generation facilities, earthen dam, concrete spillway, tailrace and retaining structures fully removed, and the upstream channel and floodplain restored to pre-dam conditions. To minimize the transport and improve stabilization of the sediment within the reservoir, the reservoir would be drawn down in a controlled manner. Hydraulic dredging would be performed to approximate the river's original meander to allow the river to re-establish its course through the current reservoir. Contaminated sediments, if present, would be hauled off site and disposed of properly.

Schematics for the full removal scenario for the reservoir reservation for each dam structure are provided in their respective appendices of A through C.

3.2 LIMITATIONS

- Prior costs provided by Consumers for these scenarios and developed by Kiewit Corporation in 2022, as available, and Mead & Hunt (M&H) in 2021 were used as the foundation of these estimates. Sequencing of work follows the descriptions as detailed by M&H with additional measures incorporated following removal as part of the reservoir restoration. Estimates were supplemented and expanded based on similar experiences from other applicable dam removal projects.
- Information related to sediment volumes and characterization are estimated and assumed based on watershed research for potential hazardous contamination. As no data is available at this time, there is significant risk

associated with the uncertainty to the volumes and level of contamination for management. Unless documentation of known hazardous spills were identified for the watershed, it was considered as a mix of non-contaminated and contaminated non-hazardous sediments for removal and disposal, as detailed herein. Sediment investigations would occur after a decision to surrender and decommission were approved.

- These estimates are based on Q4 2022 dollars at the time of preparation.
- Cost estimates, by nature, are as best as the information available at the time of preparation. Estimates should be reconsidered and updated as new information is obtained and as market conditions change.
- Additional assumptions and limitations considered for each cost item to derive the presented unit pricing and quantity are detailed herein.

4 COST ESTIMATE SUMMARY

4.1 CLASS ESTIMATES

Although hydropower costs are highly site-specific with many factors contributing to cost uncertainty, costs accuracy is generally assumed to increase as project development nears completion. As such construction stage cost estimates are necessarily considered the most accurate and are quantitatively defined as such by Association for the Advancement of Cost Engineering (AACE). The level of information or considerations prepared for this independent evaluation, with limitations, would be considered as Class 5 estimate per AACE.

4.1.1 CLASS 5 ESTIMATE

This is known as the rough order of magnitude (ROM) estimate. It is used for the initial screening projects for capital expenditure planning. Since several projects are initially available, estimating each would require a tremendous amount of time and effort. Given the limited preparation, ballpark figures are usually accepted to make business plan projections. Class 5 estimates are drawn from limited information which is about 0 to 2% of the project definition. The information may be nothing more than a basic description of the plant or process, capacity, and location. That is why its accuracy ranges -50% on the low side and +100%on the high side.

Class 5 cost estimate accuracy range: -50% to +100%

Stochastic cost estimating methods are used for obtaining a Class 5 estimate. Examples of these are cost/capacity curves, rule of six-tenths, Lang factor method, scale of operation factors, and cost indices. These techniques use parametric cost estimation methods to deduce the total cost of a given project.

4.2 COST ESTIMATE SUMMARIES

Costs for each surrender scenario were calculated for (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. Detailed descriptions for each item under each scenario are provided below.

All units used in the cost estimate are U.S. Standard and all costs are in US Dollars (4th Quarter 2022 levels) if prepared by WSP. Pricing evaluated and utilized by the previous studies are based on costs at the time of their preparation (e.g. 2021 and early 2022). No price escalation was applied due to proximity in date of preparation and class 5 level estimate being prepared. The conceptual decommissioning cost estimates for each scenario by dam location are included in Appendix A through C.

4.2.1 QUANTITIES AND UNIT COSTS

Quantities of pieces of equipment and/or bulk material commodities used in the cost estimates were intended to be reasonable and representative of projects of this type. Material quantities were prepared by M&H in 2021 for categorial items included within their estimate. As appropriate, WSP simplified unit measurements and unit pricing for subject activities. For additional activity items incorporated by WSP, quantities were estimated from the schematic renderings prepared for each site and included within Appendix A through C, as detailed below. Upon determining corrective unit quantities and unit costs, cost components for each activity were determined by the multiplication of the unit quantity by unit cost, rounded to the nearest whole dollar.

4.2.2 UNCERTAINTY AREAS

This estimate will be based on similar experiences from other projects. Therefore, some specific information about each site is unknown. Additional studies would be needed to determine physical and chemical characteristics of soils and sediments, potential costs required to manage and dispose of potentially contaminated sediments upstream of the structures, type of vegetation and presence of non-native species, archaeological resources and historic structures, hydrology and hydraulic characteristics, as well as ecology and biology upstream and downstream of the structures.

4.2.3 HARDY DAM COST ESTIMATE ACTIVITIES`

Table 4.1 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.1 Hardy Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Remove Transformer & Lines from Powerhouse to 138-kV		X	X
	Leave Powerhouse Intact	X

	Construction Management, Biological Monitoring and O&M	X	X	X
Contingency	Cost Contingency	X	X	X

Remove Transformer & Lines from Powerhouse to 138-kV

Lump sum cost was taken from the M&H cost estimate for removal of the transformer and lines to the 138-kV Croton line. The partial and full removal options assume that the Hardy Plant would be demolished and therefore, electricity would no longer be required.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H cost estimate. The powerhouse structure would be left in place under the non-power operation option. Once the electrical generating equipment had been removed, water intake into the power plant would be plugged with concrete and the power conduits beneath the powerhouse would be filled with sand.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary. Work includes approximately 635-station of the access road to be removed with the remaining left to provide access to the 138-kV corridor.

Remove Septic Tank/Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 73 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Demolish & Remove Intake Structure and Footbridge

Lump sum cost was taken from the M&H cost estimate. Under the partial and complete removal options, the intake structure and footbridge would be demolished, and material removed to an off-site disposal area.

Remove or Lay-Up Equipment

Lump sum cost was taken from the M&H cost estimate. Under the non-power operation option, the turbine-generator would be disabled, and all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance would be decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons ("CFCs") and other hazardous materials routinely associated with the plant's electromechanical equipment.

Remove all Powerhouse Equipment

Lump sum cost was taken from the M&H estimate. Under the partial and full removal options, all the plant electromechanical equipment, controls, protection, and station transformers would be removed from the powerhouse during its decommissioning and transported to an off-site disposal area.

Demolish & Remove Powerhouse Including Spill Tubes, Intake/Tailrace, Retaining Wall & Aprons

Lump sum cost was taken from the M&H estimate with a 50% contingency applied to the lump sum total to account for material quantity variation presented by M&H. Per the M&H estimate, the scope of work for both the partial and full removal scenarios include demolition of the roof, masonry superstructure, reinforced concrete substructure and foundation, substation, gates and valves, tailrace guide walls and aprons, and upstream and downstream sheet pile cutoffs. All the demolished material would be transported offsite for disposal in a designated landfill area.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Demolish and Remove Auxiliary Spillway

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate for this cost activity includes either partial or full decommissioning and removal of the spillway structure. All demolished material would be transported offsite for disposal in a designated landfill/recycled (salvage).

Drain 3,902-Acre Reservoir

Lump sum cost was taken from the M&H cost estimate. Under the partial and complete removal options, the reservoir would be drained in a controlled manner through the powerhouse during removal of the powerhouse structure, intake tower, penstocks, and a section of the embankment dam. The removal will be staged and the effect of lowering the reservoir on project wetlands will be monitored monthly throughout the process. Once these elements of the project have been removed, the embankment dam would be breached sufficiently to allow the 100-year-flood flow to pass through the natural river channel located to the right of the powerhouse structure.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Excavation

Cubic yard unit price was taken from the M&H estimate. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Reinforced Concrete Demo

Cubic yard unit price was taken from the M&H estimate. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This item includes the demolition of reinforced concrete associated with this removal. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Sheet Piling Removal

Cost per square foot was taken from the M&H estimate. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This activity accounts for sheet pile cutoff with all material disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Cost per cubic yard was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall - Sheet Piling Removal

Cost per square foot was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for sheet pile cutoff with all material disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal, a 300-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging

Cubic yard unit price was taken from the M&H estimate. It is assumed that the 300-foot-wide main channel will be re-established with limited dredging. According to M&H's opinion, approximately 1,048,407 cubic yards of material will need to be removed to clear fine-grain sediments and re-establish the channel where necessary beyond the pilot channel. This amount is prorated at 85% to account for limited dredging within the new impoundment for the partial removal. For secondary tributary connections, which total 36,000 linear feet, it is assumed that dredging will occur at a width of 50-feet and an average depth of 4-feet, resulting in an estimated 300,000 cubic yards of material to be removed.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Remove Contaminated Sediments – Removal

Cubic yard unit price was taken from the M&H estimate. Consideration of dredging operation only for removal and loading into a disposal truck of an initial layer of contaminated non-hazardous sediments at the onset of removal. Quantity considers a 12-inch layer of non-hazardous contaminated materials is removed from 10% of the reservoir area for disposal at a registered landfill accepting non-hazardous sediments for both the partial and full removal scenarios.

Remove Contaminated Sediments – Disposal

Unit cost consideration for transportation and disposal fee of non-hazardous contaminated sediments at an offsite facility accepting material.

Salvage

Lump sum cost was taken from the M&H estimate for salvage pricing as detailed in the M&H estimate report. Due to its lower salvage value at the time of their estimate and the level of this cost estimate, pricing for updated market value in salvage rates was not evaluated/applied as it was expected to rebound, which would reduce overall costs considered.

Reconstruct Roadway – Road

Under the partial and complete removal options, the existing 36th Street, which crosses the top of the earth embankment dam, would need to be reconstructed.

Reconstruct Roadway – Bridge

Under partial and complete removal options, the existing 36th Street, which crosses the top of the earth embankment dam, would need to be replaced with a new bridge approximately 875 feet long and 28 feet wide to span the river and descend the east side of the valley.

Apply Erosion Control Measures - Silt Fence

Price per linear foot and unit quantity was taken from the M&H estimate. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Grading & Surface Preparation/Amendments

WSP added cost for grading and surface preparation/amendments for newly exposed sediments within the reservoir for floodplain restoration.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 15% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the Muskegon River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 85% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the Muskegon River, as well as both banks for all tributary lengths.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Channel Creation - Riffle Section at Downstream Tie In

This item involves the placement of river rock along a portion at the downstream limits of work for the riffle bed reconstruction. It is assumed that the riffle section will be 300-feet-wide, 1,000-feet-long, and 2-feet-deep for the full removal while only 500-feet-long for the partial removal. The river rock will be strategically placed to enhance the stability and functionality of the riffle, promoting better water flow and habitat conditions.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot-drop and 3-foot-footer) and 4-foot-width.

Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 95-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 9-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Owner's Cost

An owner’s cost of 15% of the construction subtotal, less contaminated sediment disposal due to its volatility of occurrence and price, was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $796,680 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring and O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) were applied. These costs may be variable as the design develops and permit stipulations are identified.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.4 ROGERS DAM COST ESTIMATE ACTIVITIES

Table 4.2 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.2 Rogers Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Continued Use of 46-kV Substation	X	X	X
	Remove Overhead Lines Between Powerhouse and MTB No. 1	X	X	X
	Move Distribution Line from Plant Bus		X	X
Decommissioning and Demolition	Leave Powerhouse Intact	X

Continued Use of 46-kV Substation

Lump sum cost was taken from the M&H estimate. Work would include retirement and replacement of existing equipment to the Rogers Plant to all continued functionality and service of the 46-kV substation for local distribution to Big Rapids and Stanwood following the surrendering scenario for all three scenarios.

Remove Overhead Lines Between Powerhouse and MTB No. 1

Linear footage and price per linear foot was taken from the M&H. Work includes removal of the overhead lines between the powerhouse and MTB No. 1 for all three scenarios.

Move Distribution Line from Plant Bus

Linear footage and price per linear foot was taken from the M&H. Under the partial and full removal, the distribution lines would no longer be required and removed entirely. Under the no-power generation scenario, electricity for the spillway operations would be required and services left in place to the plant for operation and maintenance of the plant.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H estimate. Scope of work outlined by M&H for the no-power generation scenario includes addressing public safety and environmental concerns to leave the powerhouse in place. This includes installation of precast concrete stoplogs in the power intake and draft tube exits to isolate the powerhouse water conduits following electromechanical equipment removal. Once isolated from reservoir and tailrace, the power conduits would be filled with sand up to the generator gallery floor.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Storage Building

Lump sum cost was taken from the M&H estimate. The onsite storage building will be demolished and disposed of offsite for all three scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary. Work includes approximately 600 feet of the access road to be removed with the remaining left to provide access to the relocated overhead distribution line.

Remove Septic Tank / Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 11 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove or Lay-Up Equipment

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the turbine-generator with all the electromechanical and service equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Remove All Powerhouse Equipment

Lump sum cost was taken from the M&H estimate. For the partial and full removal scenarios, all the powerhouse equipment related to the generation of electricity would be decommissioned and disposed of offsite.

Demolish & Remove Powerhouse Including Spill Tubes, Intake/Tailrace, Retaining Wall & Aprons

Lump sum cost was taken from the M&H estimate with a 50% contingency applied to the lump sum total to account for material quantity variation presented by M&H. Per the M&H estimate, the scope of work for both the partial and full removal scenarios include demolition and disposal of the powerhouse, including roof, masonry superstructure, reinforced concrete substructure and foundation, trashracks, gates and valves, approach and tailrace guide walls and aprons, and upstream and downstream sheet pile cutoffs. All demolished material would be transported offsite for disposal in a designated landfill.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Demolish And Remove Service Spillway Including Concrete Weir and Apron

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate for this cost activity include demolition and removal of the spillway structure, including gates, bridge, concrete weir, and apron. For the partial removal, the spillway guide walls, weir and apron would remain in place with gates removed. For the full removal, the demolition would be complete and include approach guide walls and apron, stilling basin weir, and tailrace guide walls and apron. The upstream sheet pile cutoff would also be removed to below the natural river channel level. All demolished material would be transported offsite for disposal in a designated landfill/recycled (salvage).

Drain 449-Acre Reservoir

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate includes draining the reservoir in a controlled manner through the powerhouse and spillway structure as they are demolished and removed in a staged process. The staged removal of the spillway would require that a steel sheet pile, gravel-filled cellular cofferdam with removable stoplogs, be placed upstream of the spillway. This cofferdam would allow the demolition of the entire spillway while regulating the diversion of river flows through the powerhouse structure. Once the reservoir has been lowered to the spillway foundation slab, the cofferdam would be removed to allow flows to be diverted through the previous spillway area to the natural river channel, and the remaining powerhouse bays, guide walls, and aprons would be removed. Once the powerhouse and spillway structures have been removed, the removal of the embankment dam would be completed. WSP price considers cofferdam and diversion for both scenarios and concrete stoplogs.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Excavation

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Reinforced Concrete Demo

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Sheet Piling Removal

Square foot unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for sheet pile cutoff with all material disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. The earth dams would be completely removed under the full removal scenario. It is assumed excavated earth material will stay onsite to reflect the unit price prepared by M&H.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Cubic yard unit price was taken from the M&H estimate. As part of the earth dam removal, the concrete core wall will be demolished and disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall - Sheet Piling Removal

Square foot unit price was taken from the M&H estimate. This activity accounts for the sheet pile cutoff, in which all of the sheet pile wall as part of the core wall will be removed and disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal, a 200-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging

Cubic yard unit price was taken from the M&H estimate. For both the partial and full removal scenarios, this work includes additional hydraulic dredging of the reservoir area beyond the 200-foot-wide pilot channel during the drawdown process to restore the floodplain characteristics of the Muskegon River. Unit quantities derived from M&H estimate and does not take into consideration additional volume removed for contaminated non-hazardous material. All material is considered non-contaminated and reused onsite. Following removal of the dam.

For the partial removal scenario, WSP considered an 85% quantity reduction in volume removed based on installation of a replacement weir system and upstream reservoir design to maintain a smaller impounded water level.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Remove Contaminated Sediments – Removal

Cubic yard unit price was taken from the M&H estimate. Consideration of dredging operation only for removal and loading into a disposal truck of an initial layer of contaminated non-hazardous sediments at the onset of removal. Quantity considers a 12-inch layer of non-hazardous contaminated materials is removed from the reservoir area for disposal at a registered landfill accepting non-hazardous sediments for both the partial and full removal scenarios.

Remove Contaminated Sediments – Disposal

Unit cost consideration for transportation and disposal fee of non-hazardous contaminated sediments at an offsite facility accepting material.

Salvage

Lump sum cost was taken from the M&H estimate for salvage pricing as detailed in the M&H estimate report. Due to its lower salvage value at the time of their estimate and the level of this cost estimate, pricing for updated market value in salvage rates was not evaluated/applied as it was expected to rebound, which would reduce overall costs considered.

Apply Erosion Control Measures - Silt Fence

Price per linear foot and unit quantity was taken from the M&H estimate. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 15% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the Muskegon River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 85% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the Muskegon River, as well as both banks for all tributary lengths.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Channel Creation - Riffle Section at Downstream Tie In

WSP derived cost for performing additional channel restoration for a length immediately at and above the dam that includes imported rock. For the partial removal, a 300-foot-length is considered upstream of the revised water impounded area. For the full removal, a 600-foot-length is considered for the dam footprint extending to the same termination point as the partial removal.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot-drop and 3-foot-footer) and 4-foot-width.

Fish Passage

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 26-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 6-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Owner's Cost

An owner's cost of 15% of the construction subtotal construction subtotal, less contaminated sediment disposal due to its volatility of occurrence and price, was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $225,289 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring and O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) were applied. These costs may be variable as the design develops and permit stipulations are identified.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.5 CROTON DAM COST ESTIMATE ACTIVITIES

Table 4.3 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.3 Croton Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Remove Overhead Lines Between Powerhouse and MTB No. 1		X	X
Decommissioning and Demolition	Remove Security Fencing		X	X
	Remove Storage Building		X	X
	Remove Office/Storage Building	X	X	X
	Leave Powerhouse Intact	X		
	Remove or Lay-Up Equipment	X		
	Remove Plant Access Road		X	X
	Remove Septic Tank / Drain Field		X	X
	Remove Piezometers		X	X
	Remove All Powerhouse Equipment		X	X
	Modify Spillway to Maintain Flow/Pond Level	X		
	Demolish & Remove Powerhouse Turbine Bay Including Intake / Tailrace, Retaining Walls, and Aprons		X	X
	Demolish And Remove Spillway Including Concrete Weir and Apron		X	X

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Decommissioning and Demolition	Demolish & Remove Powerhouse Generator Hall			X
	Drain 1,209-Acre Reservoir		X	X
	Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Excavation		X	
	Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Reinforced Concrete Demo		X	
	Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Sheet Piling Removal		X	
	Demolish/Remove Entire Earth Dam and Core Wall - Excavation		X	X
	Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition			X
	Demolish/Remove Entire Earth Dam and Core Wall - Sheet Piling Removal			X
	Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel		X	X
	Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging		X	X
	Remove Accumulated Non-Contaminated Sediments - Mob/Demo		X	X
Abatement and Regulated Material Removal	Remove Contaminated Sediments - Removal		X	X
	Remove Contaminated Sediments - Disposal		X	X
Salvage	Salvage		X	X
	Apply Erosion Control Measures - Silt Fence		X	X

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Environmental and Restoration	Apply Erosion Control Measures - Riprap Protection		X	X

	Construction Management, Biological Monitoring and O&M	X	X	X
Contingency	Cost Contingency	X	X	X

Remove Overhead Lines Between Powerhouse and MTB No. 1

Linear footage and price per linear foot was taken from the M&H. Work includes removal of the overhead lines between the powerhouse and MTB No. 1 as part of the partial and full removal scenarios.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Storage Building

Lump sum cost was taken from the M&H estimate. The onsite storage building will be demolished and disposed of offsite as part of the partial and full removal scenarios.

Remove Storage / Office Building

Lump sum cost was taken from the M&H estimate. The onsite storage building will be demolished and disposed of offsite for all three scenarios.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H estimate. Scope of work outlined by M&H for the no-power generation scenario includes addressing public safety and environmental concerns to leave the powerhouse in place. This includes installation of precast concrete stoplogs in the power intake and draft tube exits to isolate the powerhouse water conduits following electromechanical equipment removal. Once isolated from reservoir and tailrace, the power conduits would be filled with sand up to the generator gallery floor.

Remove or Lay-Up Equipment

Lump sum cost was taken from the M&H estimate. Scope of work for this cost activity from M&H, under the no-power generation scenario only, includes disabling the turbine-generator with all the electromechanical and auxiliary equipment related to the generation of electricity and its maintenance decommissioned and laid-up in the powerhouse. The laying-up of equipment would involve the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (CFCs) and other hazardous materials routinely associated with the plant's electromechanical equipment.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary. Work includes approximately 1,000-feet of the access road to be removed with the remaining left to provide access to the relocated overhead distribution line.

Remove Septic Tank / Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 8 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove All Powerhouse Equipment

Lump sum cost was taken from the M&H estimate. For the partial and full removal scenarios, all the powerhouse equipment related to the generation of electricity would be decommissioned and disposed of offsite.

Demolish & Remove Powerhouse Turbine Bay Including Spill Tubes, Intake/Tailrace, Retaining Wall & Aprons

Lump sum cost was taken from the M&H estimate. Per the M&H estimate, the scope of work for both the partial and full removal scenarios includes demolition and disposal of the powerhouse, including roof, masonry superstructure, reinforced concrete substructure and foundation, trashracks, gates and valves, approach and tailrace guide walls and aprons, and upstream and downstream sheet pile cutoffs. All demolished material would be transported offsite for disposal in a designated landfill.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Demolish And Remove Spillway Including Concrete Weir and Apron

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate for this cost activity include demolition and removal of the spillway structure, including gates, bridge, concrete weir, and apron. For the partial removal, the spillway guide walls, weir and apron would remain in place with gates removed. For the full removal, the demolition would be complete and include approach guide walls and apron, stilling basin weir, and tailrace guide walls and apron. The upstream sheet pile cutoff would also be removed to below the natural river channel level. All demolished material would be transported offsite for disposal in a designated landfill/recycled (salvage).

Demolish And Remove Powerhouse Generator Hall

Cubic yard unit price was taken from the M&H estimate. The powerhouse generator hall would be completely removed under the full removal scenario. As part of the powerhouse generator hall removal, the hall will be demolished and disposed of offsite.

Drain 1,209-Acre Reservoir

Lump sum cost was taken from the M&H estimate. Work per the M&H estimate includes draining the reservoir in a controlled manner through the powerhouse and spillway structure as they are demolished and removed in a staged process. The staged removal of the spillway would require that a steel sheet pile, gravel-filled cellular cofferdam with removable stoplogs, be placed upstream of the spillway. This cofferdam would allow the demolition of the entire spillway while regulating the diversion of river flows through the powerhouse structure. Once the reservoir has been lowered to the spillway foundation slab, the cofferdam would be removed to allow flows to be diverted through the previous spillway area to the natural river channel, and the remaining powerhouse bays, guide walls, and aprons would be removed. Once the powerhouse and spillway structures have been removed, the removal of the embankment dam would be completed. WSP price considers cofferdam and diversion for both scenarios and concrete stoplogs.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Excavation

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Reinforced Concrete Demo

Cubic yard unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Demolish/Remove Portion of Earth Dam to Create Sufficient Breach-Sheet Piling Removal

Square foot unit price was taken from the M&H estimate. Work per the M&H estimate includes removal of portions of the embankment dam and core wall between the powerhouse and spillway and the embankment dam adjacent to the powerhouse to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. The core wall sheet pile cutoff would also be removed in this portion of the dam. This activity accounts for sheet pile cutoff with all material disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall – Excavation

Cubic yard unit price was taken from the M&H estimate. The earth dams would be completely removed under the full removal scenario. It is assumed excavated earth material will stay onsite to reflect the unit price prepared by M&H.

Demolish/Remove Entire Earth Dam and Core Wall - Reinforced Concrete Demolition

Cubic yard unit price was taken from the M&H estimate. As part of the earth dam removal, the concrete core wall will be demolished and disposed of offsite.

Demolish/Remove Entire Earth Dam and Core Wall - Sheet Piling Removal

Square foot unit price was taken from the M&H estimate. This activity accounts for the sheet pile cutoff, in which all of the sheet pile wall as part of the core wall will be removed and disposed of offsite.

Remove Accumulated Non-Contaminated Sediments - Dam Pilot Channel

Cubic yard unit price and quantity was taken from the M&H estimate. For both the partial and full removal, a 300-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments - Reservoir Dredging

Cubic yard unit price derived from was taken from the of the reservoir area beyond the 300-foot-wide pilot channel during the drawdown process to restore the floodplain characteristics of the Muskegon River. Unit quantities derived from M&H estimate and does not take into consideration additional volume removed for contaminated non-hazardous material. All material is considered non-contaminated and reused onsite. Following removal of the dam.

For the partial removal scenario, WSP considered an 85% quantity reduction in volume removed based on installation of a replacement weir system and upstream reservoir design to maintain a smaller impounded water level.

Remove Accumulated Non-Contaminated Sediments - Mob/Demob

Lump sum cost was taken from the M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Remove Contaminated Sediments – Removal

Cubic yard unit price was taken from the M&H estimate. Consideration of dredging operation only for removal and loading into a disposal truck of an initial layer of contaminated non-hazardous sediments at the onset of removal. Quantity considers a 12-inch layer of non-hazardous contaminated materials is removed from the 10% of the reservoir area for disposal at a registered landfill accepting non-hazardous sediments for both the partial and full removal scenarios.

Remove Contaminated Sediments – Disposal

Unit cost consideration for transportation and disposal fee of non-hazardous contaminated sediments at an offsite facility accepting material.

Salvage

Lump sum cost was taken from the M&H estimate for salvage pricing as detailed in the M&H estimate report. Due to its lower salvage value at the time of their estimate and the level of this cost estimate, pricing for updated market value in salvage rates was not evaluated/applied as it was expected to rebound, which would reduce overall costs considered.

Apply Erosion Control Measures - Silt Fence

Price per linear foot and unit quantity derived from M&H estimate. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures - Riprap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 15% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the Muskegon River.

Bank Stabilization - Live Stakes & Jute Mat

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 85% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix B for the Muskegon River, as well as both banks for all tributary lengths.

Habitat Restoration – Seeding

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Habitat Restoration – Planting

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 50% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Channel Creation - Riffle Section at Downstream Tie In

WSP derived cost for performing additional channel restoration for a length immediately at and above the dam that includes imported rock. For the partial removal, a 300-foot-length is considered upstream of the revised water impounded area. For the full removal, a 600-foot-length is considered for the dam footprint extending to the same termination point as the partial removal.

Sea Lamprey Control Structure

WSP added cost. To address non-native sea lamprey from migrating upstream, a barrier will need to be designed/installed to prevent their specific passage under the full removal scenario. Costs were considered equivalent for this type of structure as to the concrete weir for the partial removal.

Fish Passage w/ Sea Lamprey Control

WSP added cost. To address fish passage through the existing structure, a fish passage structure would be designed and installed under the no-power and partial removal scenarios. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the no-power scenario, 42-vertical-feet was derived from available lidar/topography information for the local area. Under the partial removal scenario, a 6-vertical-foot drop in water height considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot drop and 3-foot footer) and 4-foot width.

Owner's Cost

An owner’s cost of 15% of the construction subtotal, less contaminated sediment disposal due to its volatility of occurrence and price, was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package

and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $400,000 for a fish ladder design and $351,752 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring and O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) were applied. These costs may be variable as the design develops and permit stipulations are identified.

Cost Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.6 COST ESTIMATE RESULTS SUMMARY

The full conceptual decommissioning cost estimate for each dam site and scenario are provided in Appendix A through C. Tables 4.4 to Table 4.6 provide a summary of total cost by category for Hardy, Rogers, and Croton dams, respectively.

Table 4.4 Hardy Dam Cost Estimate Results Summary

DESCRIPTION	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	$239,902	$115,858	$115,858
Decommissioning and Demolition	$177,116	$35,545,192	$44,445,379
Abatement and Regulated Material Removal	-	$92,596,539	$92,596,539
Salvage	-	$ (135,398)	$ (135,398)
Environmental and Restoration	$4,750,000	$86,425,669	$91,712,779
Subtotal	**$5,167,018**	**$214,547,860**	**$228,735,157**
Project Indirect	$2,674,281	$26,315,002	$28,823,398
Contingency Cost	$516,702	$21,454,786	$22,873,516
Total Project Cost	**$8,358,001**	**$262,317,648**	**$280,432,071**

Note: Variation between totals in the estimates shown in this report and the April 2024 Road Map are due to the following:

1. Duplicate items for seeding the former reservoir bottom were identified in the partial and full removal, one generated from M&H in 2021 and one prepare by WSP. The duplicative pricing from M&H 2021 was removed.
2. Rounding of quantities to the next whole integer were applied in the estimates herein.
3. Verifications of quantity by unit price to equate to WSP Opinion of Costs, rounded to the next whole dollar were applied in the estimates herein.
4. Revision in application of project indirect costs for consistency

Table 4.5 Rogers Dam Cost Estimate Results Summary

DESCRIPTION	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	$66,139	$73,239	$73,239
Decommissioning and Demolition	$517,252	$19,612,261	$24,476,039
Abatement and Regulated Material Removal	-	$7,963,832	$7,963,832
Salvage	-	$(31,000)	$(31,000)
Environmental and Restoration	$1,300,000	$24,127,060	$26,457,656
Subtotal	**$1,883,391**	**$51,745,392**	**$58,939,766**
Project Indirect	$1,167,057	$9,453,915	$10,528,762
Contingency Cost	$188,340	$5,174,540	$5,893,977
Total Project Cost	**$3,238,788**	**$66,373,847**	**$75,362,505**

Note: Variation between totals in the estimates shown in this report and the April 2024 Road Map are due to the following:

1. Rounding of quantities to the next whole integer were applied in the estimates herein.
2. Verifications of quantity by unit price to equate to WSP Opinion of Costs, rounded to the next whole dollar were applied in the estimates herein.
3. Revision in application of project indirect costs for consistency

Table 4.6 Croton Dam Cost Estimate Results Summary

DESCRIPTION	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	-	$71,000	$71,000
Decommissioning and Demolition	$474,776	$31,254,938	$36,447,317
Abatement and Regulated Material Removal	-	$28,690,199	$28,690,199
Salvage	-	$(47,350.00)	$(47,350)
Environmental and Restoration	$2,100,000	$44,310,025	$51,783,317
Subtotal	**$2,574,776**	**$104,278,812**	**$116,944,483**
Project Indirect	$1,490,563	$16,179,165	$18,375,629
Contingency Cost	$257,478	$10,427,882	$11,694,449
Total Project Cost	**$4,322,817**	**$130,885,859**	**$147,014,561**

Note: Variation between totals in the estimates shown in this report and the April 2024 Road Map are due to the following:

1. Rounding of quantities to the next whole integer were applied in the estimates herein.
2. Verifications of quantity by unit price to equate to WSP Opinion of Costs, rounded to the next whole dollar were applied in the estimates herein.
3. Revision in application of project indirect costs for consistency

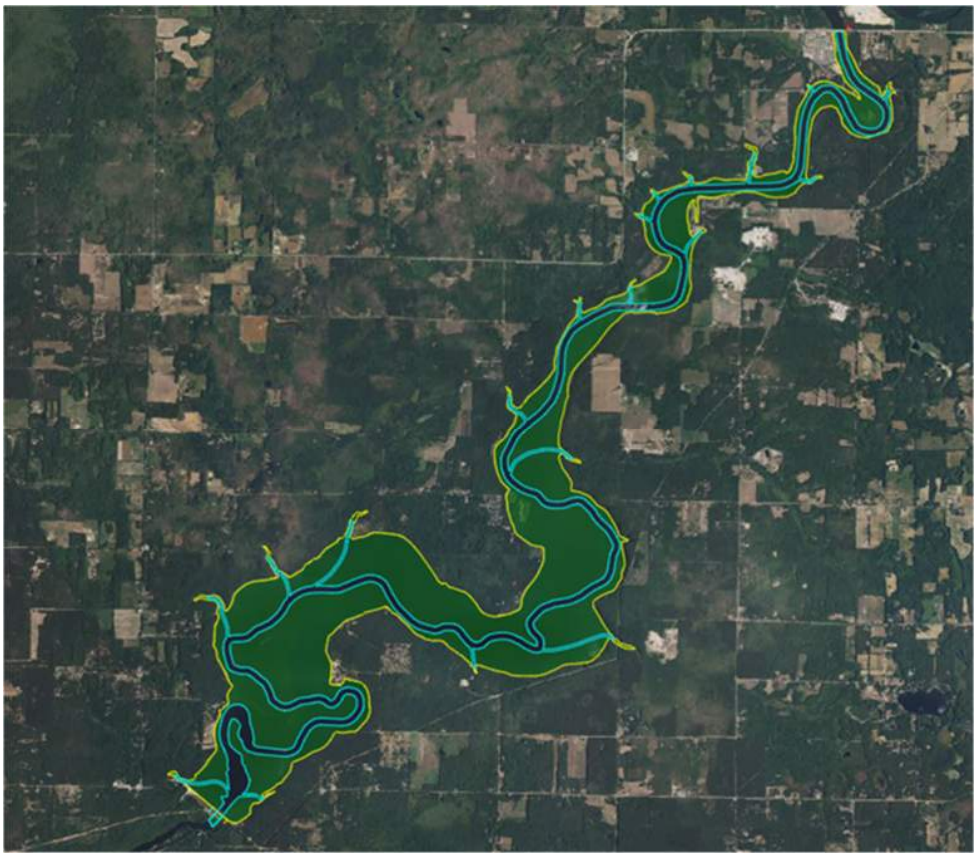
APPENDIX

A HARDY DAM HYDROELECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

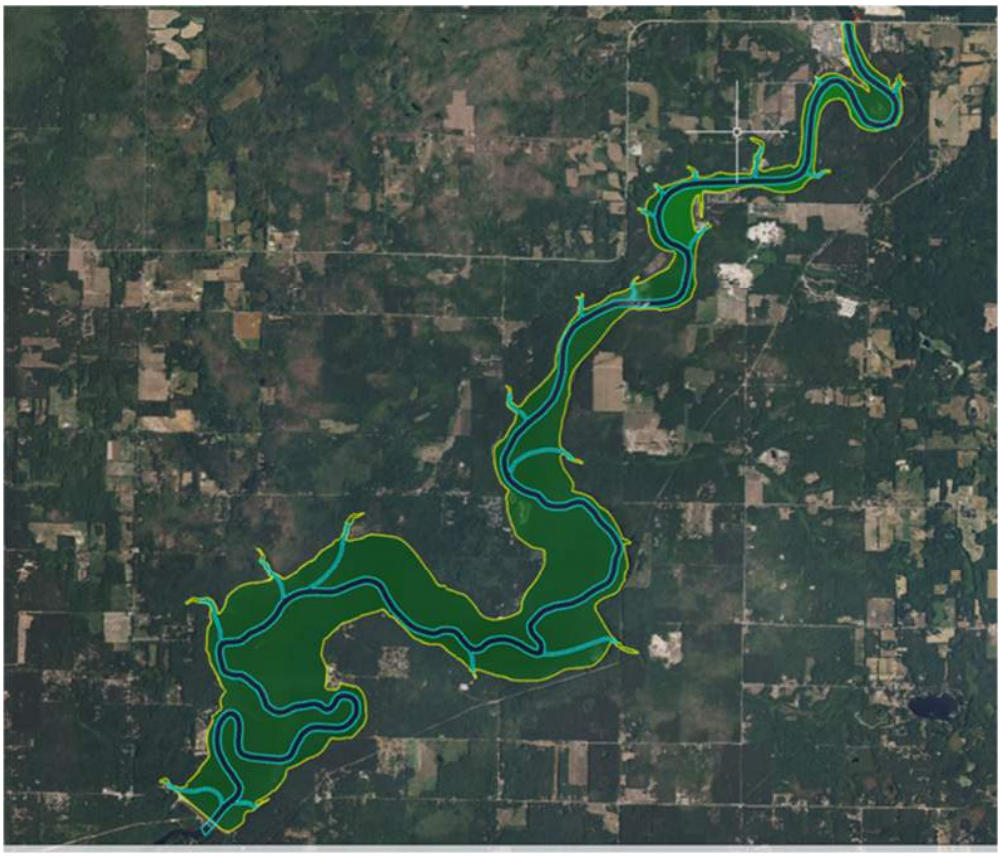


A-1 HARDY DAM SITE SUMMARY

Site Characteristics

- A 114-foot-high and 2,600-foot-long earth embankment dam section with a concrete core wall.
- A 600-foot-long fixed-crest emergency spillway with a concrete-lined (for the upper 880 feet) discharge channel.
- A reservoir with a normal surface area of 3,902 acres at elevation 822.0 feet (USGS datum) and a gross storage of 134,973 acre-feet with depths varying 70'-100' within the channel that meanders through the impoundment.
- A steel-framed concrete-and-masonry intake structure with upper and lower intake openings.
- Three concrete penstocks to convey water from the lower intake opening to the intake tower.
- Three steel-lined concrete penstocks to convey water from the intake tower to the powerhouse.
- A steel-framed concrete-and-masonry powerhouse containing three generating units with a total installed capacity of 29,229 kW.
- 200-foot-long concrete apron with retaining walls in the tailrace. 200-foot-long concrete apron with retaining walls in the tailrace.
- Hydro plant is a peaking facility and regulates flow downstream to the Croton Dam.
- Associated appurtenant structures.

Surrendering – Partial Removal



- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Mitigates water quality and fish passage interests from Michigan DNR
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.
  - Auxiliary spillway and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
  - Water quality (temperature and DO) may still be out of compliance for cold water fisheries under License Article 405.
  - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a SIGNIFICANT HAZARD POTENTIAL

because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:

- Several (>30) inhabited residential properties along left bank between 800 FT to 7,000 FT downstream of dam
- Hardy Dam Recreation Area located approximately 3,000 FT downstream of dam

- Key Considerations
  - Evaluate impact loss in reservoir has on neighboring properties with riparian access and recreational use/access.
    - The majority of reservoir riparian boundary is forested and owned by Consumers, but there are several parks, campgrounds (with dock space), marinas and boat ramps that would likely see significant shoreline retreat.
      - 5 major parks
      - 14 commercial marinas
      - Club and homeowner association uses
      - Individual and group docking sites.
    - Evaluations should include temporary impacts and mechanisms to preserve recreational access (i.e. – during drawdown) and permanent impacts.
    - Impoundment depths exceed 100' near the dam with much of the impoundment in the 70'-100'. Restoration options associated with decommissioning should develop alternatives to preserve a target depth/habitat and minimize dredging.
    - Coordination with MDNR on who would own and manage newly created bottom lands within the impoundment. MDNR focuses on managing newly created bottom lands to restrict non-public development.
    - Under Mead & Hunt assumptions, approximately 3,902 acres converted from open-water impoundment to a 200' wide channel occupying approximately 620 acres. Significant planning and analysis required to determine how to manage existing recreational features under reduced reservoir limits
  - Baseline Studies - Sediment Characterization & Bathymetry
    - Potential for contaminated sediment is significant influence on costs. Grain size distribution also critical for determining dredge volumes required.
    - Bathymetry data critical to model propose conditions to develop preliminary plans and impacts to neighboring stakeholders, recreational features, and aquatic habitat.

Surrendering – Full Removal

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Mitigates water quality and fish passage interests from Michigan DNR
  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.
- Key Considerations
  - Evaluate impact loss in reservoir has on neighboring properties with riparian access and recreational use/access.
    - The majority of reservoir riparian boundary is forested and owned by Consumers, but there are several parks, campgrounds (with dock space),

marinas and boat ramps that would likely see significant shoreline retreat.
    - 5 major parks
    - 14 commercial marinas
    - Club and homeowner association uses
    - Individual and group docking sites.
  - Evaluations should include temporary impacts and mechanisms to preserve recreational access (i.e. – during drawdown) and permanent impacts.
  - Impoundment depths exceed 100' near the dam with much of the impoundment in the 70'-100'. Restoration options associated with decommissioning should develop alternatives to preserve a target depth/habitat and minimize dredging.
  - Coordination with MDNR on who would own and manage newly created bottom lands within the impoundment. MDNR focus on managing newly created bottom lands to restrict non-public development.
  - Under Mead & Hunt assumptions, approximately 3,902 acres converted from open-water impoundment to a 200' wide channel occupying approximately 620 acres. Significant planning and analysis required to determine how to manage existing recreational features.
- Baseline Studies - Sediment Characterization & Bathymetry
  - Potential for contaminated sediments is significant influence on costs. Grain size distribution also critical for determining dredge volumes required.
  - Bathymetry data critical to model propose conditions to develop preliminary plans and impacts to neighboring stakeholders, recreational features, and aquatic habitat.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database.

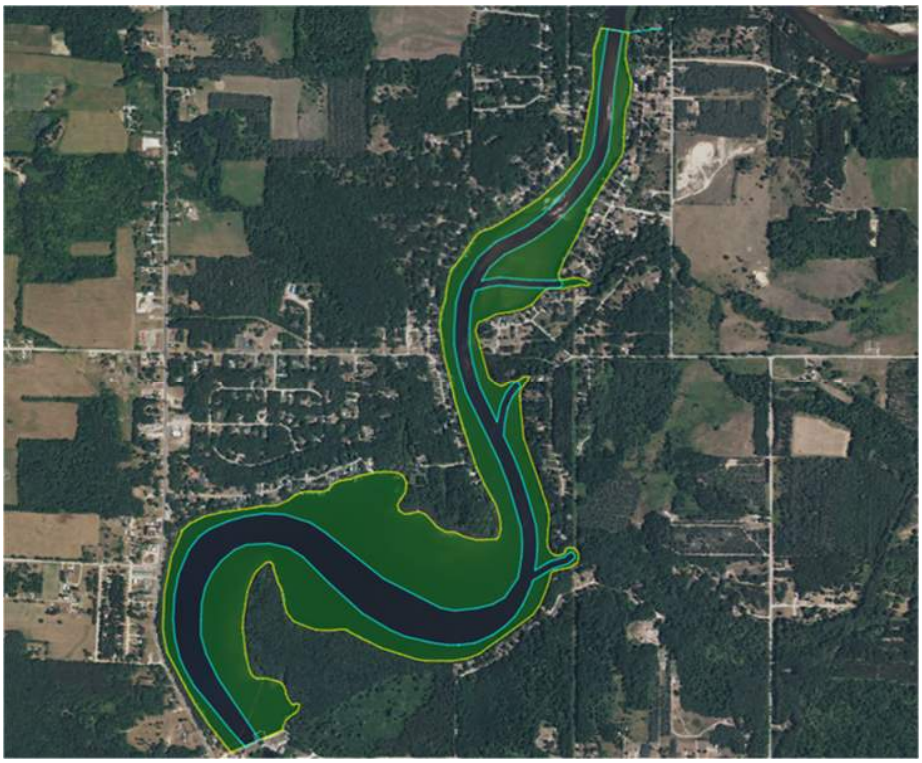
APPENDIX

B ROGERS DAM HYDROELECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

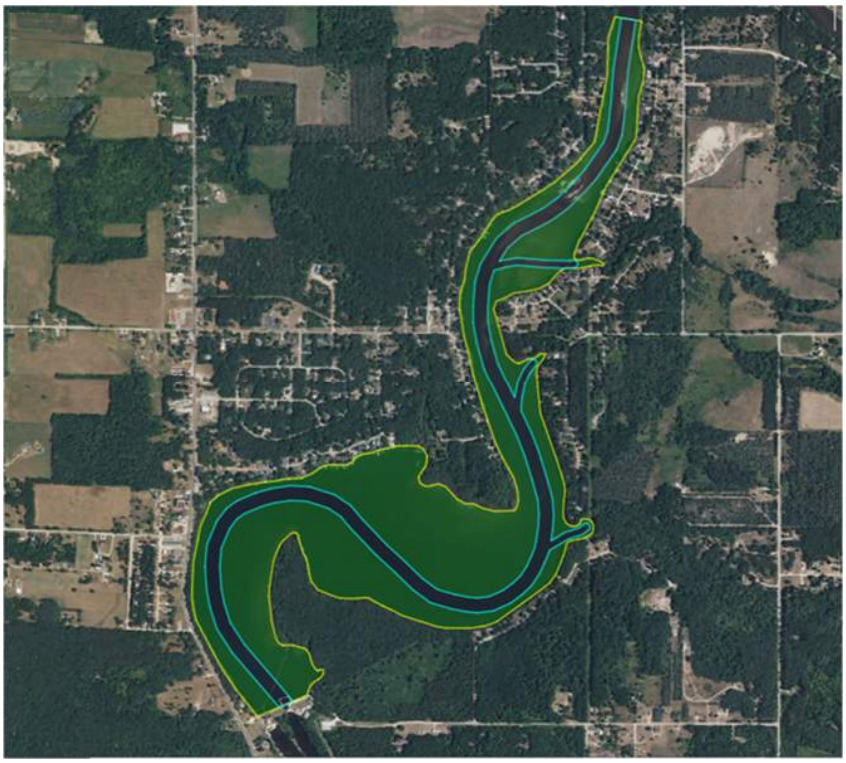


B-1 ROGERS DAM SITE SUMMARY

Site Characteristics

- Three earth embankment dam sections (one section 48 feet high and two sections 40 feet high), each with a concrete core wall and totaling 600 feet long.
- A 40-foot-high, 156-foot-long concrete spillway with six steel radial gates, a defunct log chute, and a concrete-lined discharge channel extending approximately 100 feet downstream.
- A reservoir with a normal surface area of 449 acres at elevation 861.6 feet (U.S. Geological Survey [USGS] datum) and a gross storage of 4,678 acre-feet.
- Reservoir shoreline spans approximately 21.3 miles and contains an estimated 200+ private parcels with riparian frontage, Mecosta Township Ulrich Park, and two MDNR managed boat launches.
- A concrete-and-masonry powerhouse containing four generating units with a total installed capacity of 5,418 kilowatts (kW).
- A 20-foot-long concrete apron with retaining walls in the powerhouse tailrace.
- Associated appurtenant structures.

Surrendering – Partial Removal



- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates regulatory requirements for run-of-river operation coordination with Croton Dam
  - Eliminates risks of water quality violations in future years from elevated temperatures (not specifically an issue now but thermal loading in Rogers manifests in Hardy and Croton)
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.
  - Auxiliary spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
  - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a SIGNIFICANT HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes,

agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:

- 3 inhabited residential properties located along right bank between 300 FT to 700 FT downstream of dam
- 10 inhabited residential properties located along left bank side at around 3,000 FT downstream of dam
- S. State Street Bridge approximately 3,000 FT downstream of dam
- Rt. 131 Bridge approximately 6,300 FT downstream of dam

- Key Considerations
  - Evaluate impact loss in reservoir has on neighboring properties with riparian access and recreational use/access.
    - There are a number (~200+) waterfront private parcels with riparian access that would likely experience shoreline retreat or change as a result of reservoir lowering. Evaluation of proposed conditions critical to early engagement with stakeholders.
    - Mecosta Township Ulrich Park.
    - MDNR manages Mecosta-Big Rapids Township Line Boat Launch & Rogers Height Boat Launch.
    - Evaluate options to perform additional dredging to create tributaries/canals to preserve water access to private properties and recreational facilities or construct new recreational facilities/parks within newly created bottomland/shoreline.
    - Evaluations should include temporary impacts and mechanisms to preserve recreational access (i.e. – during drawdown) and permanent impacts.
    - Coordination with MDNR on who would own and manage newly created bottom lands within the impoundment. MDNR focus on managing newly created bottom lands to restrict non-public development.
    - Under Mead & Hunt assumptions, approximately 499 acres converted from open-water impoundment to a 200' wide channel occupying approximately 75 acres.
  - Baseline studies including sediment characterization and bathymetry are critical to planning and alternative evaluation.
    - Potential contaminants have potential to drive costs considerable if removal is required.
    - Sediment characterization would enable planning for future reuse of dredged sediment to create wetlands, transition areas and uplands within newly created riparian corridor.
    - Updated bathymetry data would enable preliminary modeling of proposed conditions and impacts to neighboring stakeholders, recreational features and maintaining tributary connections.

Surrendering – Full Removal

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates regulatory requirements for run-of-river operation coordination with Croton Dam.
  - Eliminates risks of water quality violations in future years from elevated temperatures (not specifically an issue now but thermal loading in Rogers manifests in Hardy and Croton).
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.
- Key Considerations
  - Evaluate impact loss in reservoir has on neighboring properties with riparian access and recreational use/access.
    - There are a number (~200+) waterfront private parcels with riparian access that would likely experience shoreline retreat or change as a result of reservoir lowering. Evaluation of proposed conditions critical to early engagement with stakeholders.

- Mecosta Township Ulrich Park within buffer zone.
- MDNR manages Mecosta-Big Rapids Township Line Boat Launch & Rogers Height Boat Launch.
- Evaluate options to perform additional dredging to create tributaries/canals to preserve water access to private properties and recreational facilities or construct new recreational facilities/parks within newly created bottomland/shoreline.
- Evaluations should include temporary impacts and mechanisms to preserve recreational access (i.e. – during drawdown) and permanent impacts.
- Coordination with MDNR on who would own and manage newly created bottom lands within the impoundment. MDNR focus on managing newly created bottom lands to restrict non-public development.
- Under Mead & Hunt assumptions, approximately 499 acres converted from open-water impoundment to a 200' wide channel occupying approximately 75 acres.

- Baseline studies including sediment characterization and bathymetry are critical to planning and alternative evaluation.

	Drain 449-acre reservoir	LS	$ 957,351.00	1	$ 957,351.00
	Demolish/remove entire earth dam and core wall - excavation	CY	$ 14.64	84,952	$ 1,243,545.00
	Demolish/remove entire earth dam and core wall - reinforced concrete den	CY	$ 207.00	500	$ 103,500.00
	Demolish/remove entire earth dam and core wall - sheet piling removal	SF	$ 2.36	14,000	$ 33,032.00
	Remove accumulated non-contaminated sediments - Dam Pilot Channel	CY	$ 11.81	136,800	$ 1,615,509.00
	Remove accumulated non-contaminated sediments - Reservoir Dredging	CY	$ 7.09	2,357,644	$ 16,716,597.00
	Remove accumulated non-contaminated sediments - Mob/Demob	LS	$ 118,077.00	1	$ 118,077.00
Abatement and Regulated Material Removal	Remove contaminated Sediments - Removal	CY	$ 7.09	54,143	$ 383,871.00
	Remove contaminated Sediments - Disposal	TON	$ 70.00	108,285	$ 7,579,961.00
Salvage	Salvage	LS	$ (31,000.00)	1	$ (31,000.00)
Environmental and Restoration	Apply erosion control measures - silt fence	LF	$ 5.00	18,000	$ 90,000.00
	Apply erosion control measures - riprap protection	CY	$ 150.00	5,000	$ 750,000.00
	Reuse (grading) of non-contaminated excavated & dredged material	CY	$ 8.00	2,442,596	$ 19,540,768.00
	Bank Stabilization - Hard Structure	LF	$ 333.33	4,908	$ 1,635,984.00
	Bank Stabilization - Live Stakes & Jute Mat	LF	$ 54.53	34,672	$ 1,890,665.00
	Habitat Restoration - Seeding	Acre	$ 3,100.00	262	$ 813,720.00
	Habitat Restoration - Planting	Acre	$ 3,072.00	131	$ 403,185.00
	Channel creation - Riffle Section at downstream tie in	CY	$ 150.00	8,889	$ 1,333,334.00
	Subtotal				**$ 58,939,766.00**
Project Indirect	Owner's Cost				$ 7,703,971.00
	Baseline Studies, Engineering and Permitting				$ 1,797,594.00
	Construction Management, Biological Monitoring and O&M				$ 1,027,197.00
Contingency	Contingency				$ 5,893,977.00
Total Project Costs	**Total**				**$ 75,362,505.00**

Notes:

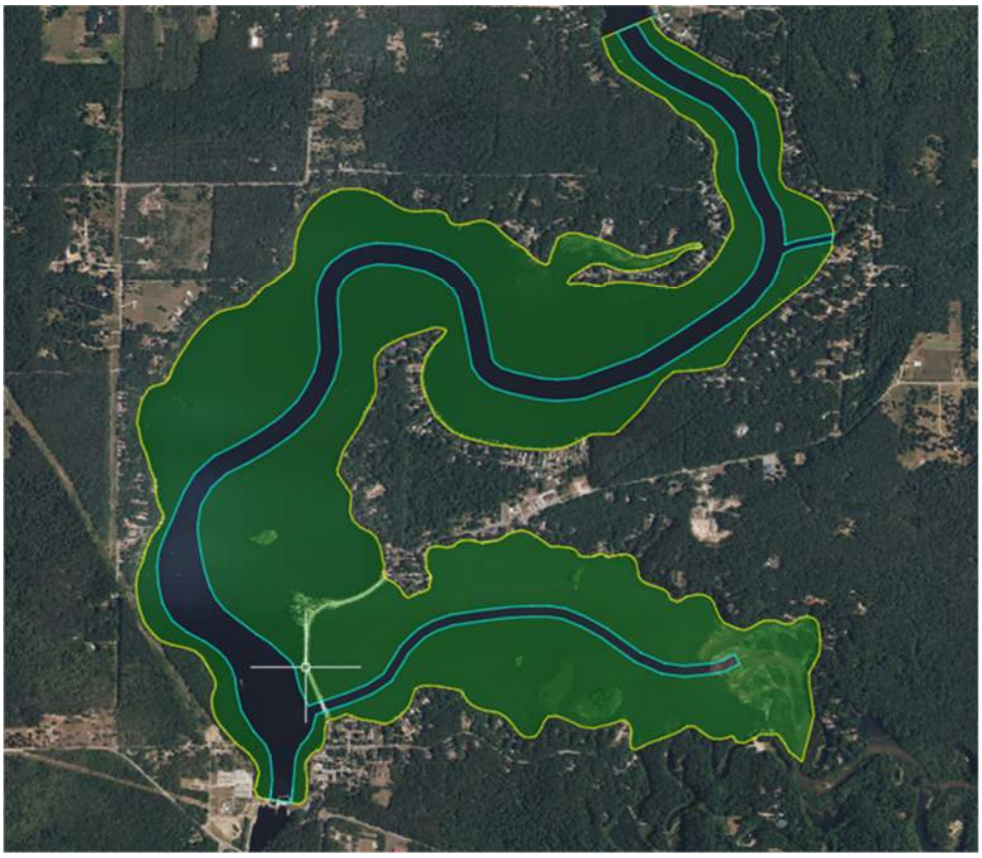
1. Removal and disposal of contaminated sediment based on limited data and actual quantity and level of effort may vary considerably.

2. Reservoir restoration assumes the excavated and dredged non-contaminated soil and sediment are reused on site and the entire newly exposed reservoir bottom will require grading, surface amendments, seeding and planting.

3. WSP unit costs based on Mead & Hunt Retirement Studies, Kiewit Infrastructure Co. Cost Estimates and WSP's internal cost database.

APPENDIX

C CROTON DAM HYDROELECTRIC PLANT CONCEPTUAL DECOMMISSIONING COST ESTIMATE

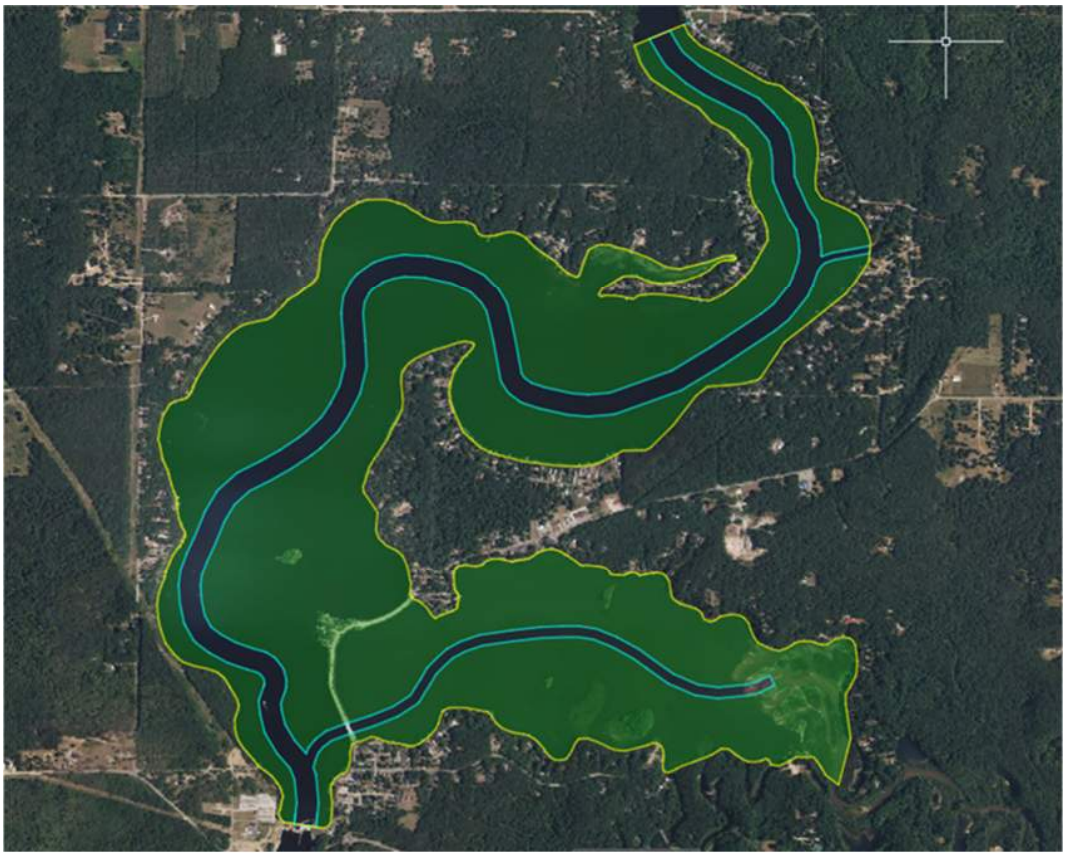


C-1 CROTON DAM SITE SUMMARY

Site Characteristics

- Two earth embankment dam sections (one section 53 feet high and one section 19 feet high), each with a concrete core wall.
- A 53-feet-high and 240-feet-long concrete spillway with eight steel radial gates, an overflow weir, and a concrete-lined discharge channel extending approximately 250 feet downstream with a 7-feet-high concrete weir located approximately 53 feet downstream.
- A reservoir with a normal surface area of 1,209 acres at elevation 722.0 feet (USGS datum) and a gross storage of 21,932 acre-feet.
- A concrete-and-masonry powerhouse containing four generating units with a total installed capacity of 7,473 kW.
- A 31-feet-long concrete apron with retaining walls in the tailrace.
- Associated appurtenant structures.

Surrendering – Partial Decommissioning



- Pros
  - Reduces legal liability and maintenance required of the existing facilities.
  - Mitigates many of the regulatory requirements associated with the existing spillway & reservoir.
  - Fish passage improved but requires installation of fish passage system; discontinuation of MDNR stocking.
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.
  - Spillways and other features not required for dam breach are left in place. Consideration should be made for future use/maintenance.
  - Water quality (temperature and potential DO may still be out of compliance for cold water fisheries under License Article 405.
  - Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational

use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a SIGNIFICANT HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists. This opinion is based on the following considerations:

- 1 inhabited residential property along left bank approximately 2,400 FT downstream of dam
- Several (>30) inhabited residential properties along right bank between 4,800 FT to 12,500 FT downstream of dam
- Croton Drive Bridge approximately 750 FT downstream of dam
- Happy Campers Campground approximately 1,500 FT downstream of dam

- Key Considerations
  - Evaluate future use of newly created shoreline and bottomland within impoundment.
    - MDNR focus on managing newly created bottomlands to restrict non-public development.
    - Property loss value evaluations for loss in property value for private properties with diminished riparian access. (500+ properties, many with dock space)
    - Under Mead & Hunt assumptions, approximately 925 acres converted from open water impoundment to upland or wetland. Considerations for selective additional dredging to preserve channels in critical areas.
  - Sea Lamprey control and treatment
    - Hydroplant turbines are critical for mixing for lampricide for downstream treatment of Sea Lamprey. Consultation with MDNR on alternative methods recommended. Currently, treatment occurs every 2-4 years at a cost of approximately $1.1M per treatment.
    - Dam is critical physical barrier for blocking upstream migration of Sea Lamprey. The dam protects nearly 200 miles of the Muskegon River. Removal should consider newly constructed barriers to limit upstream migration in consultation with MDNR.
  - Baseline Studies - Sediment Characterization & Bathymetry
    - Potential for contaminated sediments is significant influence on costs. Grain size distribution also critical for determining dredge volumes required.
    - Bathymetry data critical to model propose conditions to develop preliminary plans and impacts to neighboring stakeholders, recreational features and aquatic habitat.

Surrendering – Full Decommissioning

- Pros
  - Eliminates legal liability and maintenance of existing facilities.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
  - Eliminates issues with water quality (temperature and potential DO)
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Potential for contaminated sediments & disposal could substantially increase costs.

- Key Considerations
    - Evaluate future use of newly created shoreline and bottomland within impoundment.
        - MDNR focus on managing newly created bottomlands to restrict non-public development.
        - Property loss value evaluations for loss in property value for private properties with diminished riparian access. (500+ properties, many with dock space)
        - Under Mead & Hunt assumptions, approximately 925 acres converted from open water impoundment to upland or wetland. Considerations for selective additional dredging to preserve channels in critical areas.
    - Sea Lamprey control and treatment
        - Hydroplant turbines are critical for mixing for lampricide for downstream treatment of Sea Lamprey. Consultation with MDNR on alternative methods recommended.
        - Dam is critical physical barrier for blocking upstream migration of Sea Lamprey. The dam protects nearly 200 miles of the Muskegon River. Removal should consider newly constructed barriers to limit upstream migration in consultation with MDNR.
        - Barrier system should be installed to prevent upstream migration of invasive species (sea lamprey and round goby); refer to Fish Pass System example by Great Lakes Fishery Commission.
    - Baseline Studies - Sediment Characterization & Bathymetry
        - Potential for contaminated sediments is significant influence on costs. Grain size distribution also critical for determining dredge volumes required.
        - Bathymetry data critical to model propose conditions to develop preliminary plans and impacts to neighboring stakeholders, recreational features and aquatic habitat.

C-2 CROTON DAM NO-POWER GENERATION SCENARIO CONCEPTUAL ESTIMATE

Consumers Energy
Croton Hydroplant
Decommissioning Cost Evaluation - Non-Power Surrender

Category	Cost Activity	Unit	Unit Cost	Quantity	WSP Opinion of Cost
Decommissioning and Demolition	Remove office/storage building	LS	$ 94,462.00	1	$ 94,462.00
	Leave powerhouse intact	LS	$ 203,198.00	1	$ 203,198.00
	Remove of lay-up equipment	LS	$ 88,558.00	1	$ 88,558.00

1 EXECUTIVE SUMMARY

Consumers Energy Company (Consumers) owns and operates 13 river hydro dam facilities located on the Muskegon, Manistee, Grand, Au Sable, and Kalamazoo Rivers. The average age of these assets is 106 years old and much of each site is original construction and equipment. Consumers would need to start relicensing 11 of the 13 projects with filings signaling their intentions no later than June 30, 2029, meaning a plan for the assets should be in place within the next few years to prepare for filing with Federal Energy Regulatory Commission (FERC). In addition, FERC has recently updated their Part 12 inspection requirements. The revised inspections put more emphasis on Potential Failure Mode Analysis, updated Probable Maximum Flood, and Semi-Quantitative Risk Analysis level 2 effort for each site. These enhanced regulations require subject matter experts and facilitators to complete portions of the work.

Consumers also conducts routine inspections and commissioned studies investigating the overall conditions of the facilities. Although not comprehensive, the assessments indicate the assets are in 'fair' condition but recognizes the current operations as run-of-river is inconsistent with the original peaking designs conceding efficiency and potential generation revenue. The combination of aging assets, increasing regulatory requirements which have resulted in potentially costly upgrades to some of the Project's spillways, system operations, and expected spend on necessary maintenance to keep the plants operating has raised the question of how to extract the best value out of these assets. To achieve this goal, Consumers hired WSP USA, Inc. (WSP) to prepare the 2023 Hydropower Roadmap (Roadmap) for the 13 hydroelectric dam sites which reviewed Consumers' provided facility reports and analyzed different outcome scenarios and characterized how to achieve them. This Roadmap analyzed six scenarios that included two for relicensing, three for surrendering the license, and one to investigate divesting. Within this pursuit, an additional goal of developing an economic model as a tool to rank the potential outcomes was later added.

This report details the surrendering considerations and pricing considered in the roadmap for Webber Hydroelectric Dam, 1 of the 13 hydropower facilities located within the Grand River Watershed, in Jackson County, Michigan.

Three surrender scenarios with specific assumptions were considered in preparing the cost estimates for each surrender option:

1. Surrender– No-Power Generation: The no-power generation scenario evaluates surrender of the FERC license while not removing the dam structure. The powerhouse and spillway would be modified to maintain safe flows through the system while disconnecting generation equipment. The dam would remain in place and current reservoir levels would be maintained. Additional capital improvements would be required for long term compliance with dam safety regulations.
2. Surrender and Decommission – Partial Removal: The partial removal scenario evaluates partial removal of the dam via reduction of the earthen dam structure with full removal of the powerhouse and generation facilities. This scenario evaluates the potential to leave some form of upstream reservoir system while developing a new weir control structure. This structure would be designed to fall under state regulations (Natural Resources and Environmental Protection Act (NREPA), Part 315, Dam Safety), not FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir and to prevent the proliferation of invasive species such as the sea lampreys.
3. Surrender and Decommission - Full Removal: The full removal scenario evaluates the complete removal of the dam and reservoirs. The reservoirs would be drained, powerhouse/generation facilities and earthen dam structures fully removed, and the upstream channel and floodplain restored to pre-dam conditions.

For the subject facility and scenario, a class 5 cost estimate was prepared in Q4 2022 dollars, identifying and quantifying the value of the plant's assets and estimate of the cost of utility separation, decommissioning and demolition, abatement

and regulated material removal, environmental and restoration work of the Grand River, as well as associated project indirect costs and recommended contingency. Schematics utilized for the evaluation of the Surrender and Decommission – Partial and Full Removal for how the reservoir may be reshaped in the decommissioning restoration are presented. Additional assumptions and limitations by site are presented herein.

2 INTRODUCTION

Consumers Energy Company (Consumers) owns and operates 13 river hydro dam facilities located on the Muskegon, Manistee, Grand, Au Sable, and Kalamazoo Rivers. The average age of these assets is 106 years old and much of each site is original construction and equipment. Consumers would need to start relicensing 11 of the 13 projects with filings signaling their intentions no later than June 30, 2029, meaning a plan for the assets should be in place within the next few years to prepare for filing with Federal Energy Regulatory Commission (FERC). In addition, FERC has recently updated their Part 12 inspection requirements. The revised inspections put more emphasis on Potential Failure Mode Analysis, updated Probable Maximum Flood, and Semi-Quantitative Risk Analysis level 2 effort for each site. These enhanced regulations require subject matter experts and facilitators to complete portions of the work.

Consumers also conducts routine inspections and commissioned studies investigating the overall conditions of the facilities. Although not comprehensive, the assessments indicate the assets are in 'fair' condition but recognizes the current operations as run-of-river is inconsistent with the original peaking designs conceding efficiency and potential generation revenue. The combination of aging assets, increasing regulatory requirements which have resulted in potentially costly upgrades to some of the Project's spillways, system operations, and expected spend on necessary maintenance to keep the plants operating has raised the question of how to extract the best value out of these assets.

To achieve this goal, Consumers hired WSP USA, Inc. (WSP) to prepare the 2023 Hydropower Roadmap (Roadmap) for the 13 hydroelectric dam sites which reviewed Consumers' provided facility reports and analyzed different outcome scenarios and characterized how to achieve them. This Roadmap analyzed six scenarios that included two for relicensing, three for surrendering the license, and one to investigate divesting. Within this pursuit, an additional goal of developing an economic model as a tool to rank the potential outcomes was later added. This report details costs and considerations prepared for the Webber Hydroelectric Dam, 1 of the 13 hydropower facilities located along the Grand River system, Jackson County.

The Grand River system is the second largest river basin in Michigan. It is in the southwestern lower peninsula of Michigan and incorporates 19 counties including Hillsdale, Jackson, Washtenaw, Livingston, Calhoun, Eaton, Ingham, Shiawassee, Gratiot, Clinton, Ionia, Montcalm, Mecosta, Barry, Allegan, Kent, Newaygo, Muskegon, and Ottawa counties. The Grand River watershed drains more than 5,575 square miles of land area, and has 5,320 miles of tributaries flowing directly into the mainstream.

The three surrendering scenarios include:

- Surrender – No-Power Generation
- Surrender and Decommission – Partial Removal
- Surrender and Decommission – Full Removal.

The objective of the conceptual decommissioning cost estimate is to identify the value of the plant's assets and estimate of the cost of utility separation, decommissioning and demolition, abatement and regulated material removal, environmental work, and restoration of the Grand River, as well as associated project indirect costs and recommended contingencies.

2.1 WEBBER DAM

The Webber dam (FERC Project Number P-2566), located in the Grand River in Lyons Township, Iona County, Michigan consists of two 32-foot-high earth embankment dam sections totaling 730 ft in length with a concrete core wall and a 33-foot-high concrete service spillway with ten steel radial gates and a fixed-crest overflow section that discharges to a concrete apron extending 105 feet downstream. The reservoir, with a normal surface area of 660 acres at elevation 684.4 feet (U.S. Geological Survey [USGS] datum), has a gross storage of 6,000 acre-feet.

Additionally, the dam includes a concrete masonry powerhouse with two generating units with a total capacity of 3,250kW as well as a 186-foot long concrete-lined tailrace with retaining walls and a downstream weir. The Michigan Department of Natural Resource currently operates a fishway at the dam.

3 STUDY APPROACH

3.1 ASSUMPTIONS

WSP analyzed the costs for three scenarios involving the surrender of the hydropower facilities before the current license expires. These scenarios include 1) Surrender – No-Power Generation: 2) Surrender and Decommission – Partial Removal; and 3) Surrender and Decommission – Full removal. Detailed description of these alternatives are as follows:

Surrender – No Power Generation Operation

The no-power generation scenario evaluates surrender of the FERC license while not removing the dam structure. The powerhouse and spillway would be modified to maintain safe flows through the system while disconnecting generation equipment. The dam would remain in place and current reservoir levels would be maintained. Additional capital improvements would be required for long term compliance with dam safety regulations.

Surrender and Decommission - Partial Removal

The partial removal scenario evaluates the partial removal of the dam by reducing the earthen dam structure while fully removing the powerhouse and generation facilities. This reduction would create a sufficient breach to pass the 100-year flood through the reestablished river channel, ensuring that the incremental rise at the dam site would be less than 0.10 foot. This scenario also considers the potential to maintain some form of upstream reservoir system while developing a new weir control structure.

This structure would be designed to fall under state regulations (Natural Resources and Environmental Protection Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir and to prevent the proliferation of invasive species such as the sea lampreys. Exposed sediments and newly exposed shoreline would be stabilized and re-vegetated.

Schematics for the partial removal scenario for the dam structure are provided in Appendix A.

Surrender and Decommission - Full Removal

The full removal scenario evaluates the complete removal of the dam and reservoirs. The reservoirs would be drained, powerhouse/generation facilities, earthen dam, concrete spillway, tailrace and retaining structures fully removed, and the upstream channel and floodplain restored to pre-dam conditions. To minimize the transport and improve stabilization of the sediment within the reservoir, the reservoir would be drawn down in a controlled manner. Hydraulic dredging would be performed to approximate the river's original meander to allow the river to re-establish its course through the current reservoir. Contaminated sediments, if present, would be hauled off site and disposed of properly.

Schematics for the full removal scenario for the dam structure are provided in Appendix A.

3.2 LIMITATIONS

- Prior costs provided by Consumers for these scenarios and developed by Kiewit Corporation in 2022, as available, and Mead & Hunt (M&H) in 2021 were used as the foundation of these estimates. Sequencing of work follows the descriptions as detailed by M&H with additional measures incorporated following removal as part of the reservoir restoration. Estimates were supplemented and expanded based on similar experiences from other applicable dam removal projects.
- Information related to sediment volumes and characterization are estimated and assumed based on watershed research for potential hazardous contamination. As no data is available at this time, there is significant risk associated with the uncertainty to the volumes and level of contamination for management. Unless documentation of known hazardous spills were identified for the watershed, it was considered as a mix of non-

contaminated and contaminated non-hazardous sediments for removal and disposal, as detailed herein. Sediment investigations would occur after a decision to surrender and decommission were approved.

- These estimates are based on Q4 2022 dollars at the time of preparation.
- Cost estimates, by nature, are as best as the information available at the time of preparation. Estimates should be reconsidered and updated as new information is obtained and as market conditions change.
- Additional assumptions and limitations considered for each cost item to derive the presented unit pricing and quantity are detailed herein.

4 COST ESTIMATE SUMMARY

4.1 CLASS ESTIMATES

Although hydropower costs are highly site-specific with many factors contributing to cost uncertainty, costs accuracy is generally assumed to increase as project development nears completion. As such construction stage cost estimates are necessarily considered the most accurate and are quantitatively defined as such by Association for the Advancement of Cost Engineering (AACE). The level of information or considerations prepared for this independent evaluation, with limitations, would be considered as Class 5 estimate per AACE.

4.1.1 CLASS 5 ESTIMATE

This is known as the rough order of magnitude (ROM) estimate. It is used for the initial screening projects for capital expenditure planning. Since several projects are initially available, estimating each would require a tremendous amount of time and effort. Given the limited preparation, ballpark figures are usually accepted to make business plan projections. Class 5 estimates are drawn from limited information which is about 0 to 2% of the project definition. The information may be nothing more than a basic description of the plant or process, capacity, and location. That is why its accuracy ranges -50% on the low side and +100%on the high side.

Class 5 cost estimate accuracy range: -50% to +100%

Stochastic cost estimating methods are used for obtaining a Class 5 estimate. Examples of these are cost/capacity curves, rule of six-tenths, Lang factor method, scale of operation factors, and cost indices. These techniques use parametric cost estimation methods to deduce the total cost of a given project.

4.2 COST ESTIMATE SUMMARIES

Costs for each surrender scenario were calculated for (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. Detailed descriptions for each item under each scenario are provided below.

All units used in the cost estimate are U.S. Standard and all costs are in US Dollars (4th Quarter 2022 levels) if prepared by WSP. Pricing evaluated and utilized by the previous studies are based on costs at the time of their preparation (e.g. 2021 and early 2022). No price escalation was applied due to proximity in date of preparation and class 5 level estimate being prepared. The conceptual decommissioning cost estimates for each scenario for the subject dam are included in Appendix A.

4.2.1 QUANTITIES AND UNIT COSTS

Quantities of pieces of equipment and/or bulk material commodities used in the cost estimates were intended to be reasonable and representative of projects of this type. Material quantities were prepared by M&H in 2021 for categorial items included within their estimate. As appropriate, WSP simplified unit measurements and unit pricing for subject activities. For additional activity items incorporated by WSP, quantities were estimated from the schematic renderings prepared for the subject site and included within Appendix A, as detailed below. Upon determining corrective unit quantities and unit costs, cost components for each activity were determined by the multiplication of the unit quantity by unit cost, rounded to the nearest whole dollar.

4.2.2 UNCERTAINTY AREAS

This estimate will be based on similar experiences from other projects. Therefore, some specific information about the site is unknown. Additional studies would be needed to determine physical and chemical characteristics of soils and sediments, potential costs required to manage and dispose of potentially contaminated sediments upstream of the structures, type of vegetation and presence of non-native species, archaeological resources and historic structures, hydrology and hydraulic characteristics, as well as ecology and biology upstream and downstream of the structures.

4.2.3 WEBBER DAM COST ESTIMATE ACTIVITIES

Table 4.1 provides an outline of estimate cost activities and which activities apply to each scenario. Each activity is associated with the following categories: (1) Utility Separation, (2) Decommissioning and Demolition, (3) Abatement and Regulated Material Removal, (4) Salvage (asset recovery), (5) Environmental and Restoration, (6) Project Indirect, and (7) Contingency. A description of each activity and what is considered in deriving the unit price and quantity by scenario are detailed below.

Table 4.1 Webber Dam Cost Estimate Activities by Scenario

CATEGORY	COST ACTIVITY	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	Remove Substation		X	X
	Remove Lines from Plant to Substation		X	X
Decommissioning and Demolition	Leave Powerhouse Intact	X		
	Remove Security Fencing		X	X
	Remove Plant Access Road		X	X

	Owner's Cost	X	X	X
	Baseline Studies, Engineering and Permitting	X	X	X
	Construction Management, Biological Monitoring, And O&M	X	X	X
	Contingency	X	X	X

Remove Substation

Lump sum cost was taken from the M&H cost estimate. The substation would no longer be necessary as the facility would no longer produce electricity under the partial and full removal scenarios, therefore, the substation would be removed.

Remove Lines from Plant to Substation

Cost per linear foot was taken from the M&H cost estimate. The buried cable from the powerhouse to the substation would no longer be required under the partial and full removal scenarios, so it would be removed.

Leave Powerhouse Intact

Lump sum cost was taken from the M&H cost estimate. The powerhouse structure would be left in place under the non-power operation option. Once the electrical generating equipment had been removed, water intake into the power plant would be plugged with concrete and the power conduits beneath the powerhouse would be filled with sand.

Remove Security Fencing

Price per linear foot was taken from the M&H estimate. Security fencing for the facility would be removed and disposed of offsite as part of the partial and full removal scenarios.

Remove Plant Access Road

Price per station (100-feet-per-station) was taken from the M&H estimate. Under the partial and full removals, the access road to the powerhouse would no longer be necessary. Work includes approximately 2-station of the access road to be removed.

Remove Septic Tank/Drain Field

Lump sum cost was taken from the M&H estimate. For both the partial and full removal, work includes the removal of the plant's septic tank and drain field with contaminated material disposed offsite.

Remove Piezometers

Price per each was taken from the M&H estimate. For both the partial and full removal, the embankment dam would no longer impound the reservoir and all 7 of the project piezometers would be either excavated and removed or abandoned and capped below grade.

Remove All Powerhouse Equipment

Lump sum cost was taken from the M&H estimate. Under the partial and full removal options, all the plant electromechanical equipment, controls, protection, and station transformers would be removed from the powerhouse during its demolition and transported to an off-site disposal area.

Remove or Lay Up Equipment

Lump sum cost was taken from the M&H cost estimate. Under the non-power operation option, the turbine-generator would be disabled, and all the equipment related to the generation of electricity would be decommissioned and laid-up in the powerhouse. This includes the draining and removal of petroleum-based products from hydraulic systems and operators, as well as chlorofluorocarbons (" CFC's") and other hazardous materials.

Demolish and Remove Concrete/Masonry - Powerhouse

Price per cubic yard was taken from the estimate by M&H. Under the partial and complete removal scenarios, concrete and masonry associated with the dam and powerhouse structure will no longer be necessary and will be removed.

Remove Trash Racks

Cost per ton was taken from the M&H estimate. Under the partial and complete removal scenarios, trash racks will no longer be necessary and will be removed.

Remove Gates – Powerhouse

Cost per ton was taken from the M&H estimate. Under the partial and complete removal scenarios, gates will no longer be necessary in the powerhouse and will be removed.

Demolish and Remove Concrete - Spillway

Price per cubic yard was taken from the estimate by M&H. Under the partial and complete removal scenarios, concrete associated with the spillway will be demolished and removed and will be removed.

Remove Gates - Spillway

Cost per ton was taken from the M&H estimate. Under the partial and complete removal scenarios, gates in the spillway will no longer be necessary and will be removed.

Remove Walkway and Hoist Rails

Cost per ton was taken from the M&H estimate. Under the partial and complete removal scenarios, walkways and hoist rails will no longer be necessary and will be removed.

Remove Hoists

Cost per ton was taken from the M&H estimate. Under the partial and complete removal scenarios, hoists will no longer be necessary and will be removed.

Drain Reservoir

Lump sum cost provided from M&H cost estimate. Under the partial and complete removal options, the reservoir would be drained in a controlled manner through the powerhouse and spillway during removal of the powerhouse structure. The removal will be staged and the effect of lowering the reservoir on project wetlands will be monitored monthly throughout the process. Removal of the spillway will require the installation of a temporary cofferdam.

Remove Earth Dam: Excavation

Cubic yard unit price was taken from the M&H estimate. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Remove Portion of Earth Dam: Excavation

Cubic yard unit price was taken from the M&H estimate for a similar structure. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This activity accounts for the earth material excavation, which is considered to stay onsite for reuse above the restored floodplain.

Remove Earth Dam: Concrete Demolition

Cubic yard unit price was taken from the M&H estimate for a similar structure. Under the full removal option, the embankment dam and core wall would be removed entirely. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Remove Portion of Earth Dam: Concrete Demolition

Cubic yard unit price was taken from the M&H estimate for a similar structure. Under the partial removal option, the embankment dam and core wall would be removed to provide a breach of sufficient size to pass the 100-year flood without causing an incremental rise of more than 0.10 foot through the project site. This item includes the demolition of reinforced concrete associated with this removal. This activity accounts for the concrete demolition portion of the removal with all material disposed of offsite.

Modify Spillway to Maintain Flow/Pond Level

Lump sum cost was taken from the M&H estimate. M&H scope of work for this cost activity detail modifications to the operation of the gated spillway would be made to allow the regulation of releases from the impoundment like those that had occurred during generating operations to maintain normal reservoir operating levels. The modified operations would allow continued releases during normal and project flood conditions.

Dam Pilot Channel

Cubic yard unit price by WSP, derived from comparable projects. For both the partial and full removal, a 200-foot-wide pilot channel would be developed to approximate the river's original meander to allow the river to reestablish its course through the reservoir. This will be conducted during the drawdown process of the reservoir lowering. All material is considered non-contaminated and reused onsite following removal of the dam.

Remove Accumulated Non-Contaminated Sediments

Cubic yard unit price was taken from the M&H estimate. It is assumed that the 200-foot-wide main channel will be re-established with limited dredging. According to M&H's opinion, approximately 1,008,390 cubic yards of material will need to be removed to clear fine-grain sediments and re-establish the channel where necessary beyond the pilot channel. This amount is prorated at 66% to account for limited dredging within the new impoundment for the partial removal.

Remove Contaminated Soil

Cubic yard unit price was taken from the M&H estimate. Consideration of dredging operation only for removal and loading into a disposal truck of an initial layer of contaminated non-hazardous sediments at the onset of removal. Quantity considers a 12-inch layer of non-hazardous contaminated materials is removed from 10% of the reservoir area for disposal at a registered landfill accepting non-hazardous sediments for both the partial and full removal scenarios.

Disposal of Contaminated Soil

Unit cost consideration for transportation and disposal fee of non-hazardous contaminated sediments at an offsite facility accepting material.

Reuse (Grading) of Non-Contaminated Excavated & Dredged Material

WSP added cost for site grading of excavated and non-contaminated sediments to remain onsite. Following decommissioning of the dam and dredging of the sediments, this activity would account for the additional handling/spreading of sediments above the restored floodplain to displace and then permanently stabilize materials (accounted for in other cost activities) onsite.

Grading & Surface Preparation/Amendments

WSP added cost for grading and surface preparation/amendments for newly exposed sediments within the reservoir for floodplain restoration.

Channel Creation - Riffle Section at Downstream Tie-In

This item involves the placement of river rock along a portion at the downstream limits of work for the riffle bed reconstruction. It is assumed that the riffle section will be 200-feet-wide, 1,000-feet-long, and 2-feet-deep for the partial and full. The river rock will be strategically placed to enhance the stability and functionality of the riffle, promoting better water flow and habitat conditions.

Mobilization/Demobilization

Lump sum cost taken from M&H estimate. Work includes mobilization and demobilization of hydraulic dredging operation for all sediment removal work.

Seed Former Reservoir Bottom

WSP derived cost for providing permanent seeding of restored reservoir and dam area for stabilization of sediment/soils and reservoir restoration.

Plant Former Reservoir Bottom

WSP derived cost for providing riparian reforestation along the restored channel system. Quantity assumed 100% of the seeded areas for both the partial and full removal are planted at a 480 stem per acre with No. 2 container tree and shrubs.

Concrete Weir Installation

WSP derived costs for the partial removal scenario. This structure would be designed to fall under state regulations (Act (NREPA), Part 315, Dam Safety), rather than FERC regulations. Structures would be approximately six feet in height to be defined as the lowest hazard classification potential feasible by location while achieving the goal of maintaining some form of upstream reservoir. Unit pricing considers as pile supported reinforced concrete structure with a 9-foot-height (6-foot drop and 3-foot-footer) and 4-foot-width.

Fish Passage

WSP added cost. A fish ladder is already in place at Webber Dam so a new structure would only be necessary under the partial removal scenario. Unit quantity was derived based on water surface variation from upstream to downstream for vertical linear foot of passage necessary. Under the partial removal scenario, a 9-vertical-foot drop in water height was considered after removal of the existing dam and construction of the concrete weir to maintain small amounts of upstream ponding.

Apply Erosion Control Measures: Silt Fence

Price per linear foot and unit quantity derived WSP project experience. Work includes temporary silt fence implemented within the reservoir during dam removal and reservoir restoration until the site is stabilized and completed.

Apply Erosion Control Measures: Rip Rap Protection

WSP developed price and quantity for temporary riprap used for temporary stabilization activities during dam removal for both the partial and full removal scenarios.

Bank Stabilization - Hard Structure

WSP added cost for provided reinforced banks (riprap) for stabilization of the restored channel through the reservoir. Quantity assumes 15% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the Grand River.

Bank Stabilization - Live Stakes and Jute Matting

WSP added cost for provided bank stabilization of restored channel systems with live stakes and jute matting of the restored channel through the reservoir. Quantity assumes 85% of both banks of the restored linear footage of the main channel system depicted in the schematics presented in Appendix A for the Grand River, as well as both banks for all tributary lengths.

Salvage Value

Lump sum cost derived from M&H estimate for salvage pricing as detailed in the M&H estimate report. Due to its lower salvage value at the time of their estimate and the level of this cost estimate, pricing for updated market value in salvage rates was not evaluated/applied as it was expected to rebound, which would reduce overall costs considered.

Owner's Cost

An owner's cost of 15% of the construction subtotal, less contaminated sediment disposal, was applied to each scenario to cover Consumers costs in project management and indirect costs for implementing the surrender scenario.

Baseline Studies, Engineering and Permitting

This project indirect covers costs for an engineering firm to perform the baseline studies (environmental investigations and sampling, surveys, hydraulic modeling, etc.) required for the scenario, prepare an associated design and bid package and obtaining required regulatory. Support and developing studies to obtain FERC approval for surrendering are also considered within this project indirect.

For the non-power scenario, 3.5% of the construction subtotal with an additional $5,000 for environmental surveys of structures, $253,547 for the environmental/social impact study (prepared by M&H for the non-power evaluation) were applied.

For the partial removal scenario, 3.5% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) with an additional $400,000 for a concrete weir and fish ladder design were applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

For the full removal scenario, 3.5% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) was applied. It is assumed the price for the environmental/social impact study would be captured within the 3.5% of the construction subtotal.

Construction Management, Biological Monitoring, And O&M

This item is variable by scenario. This project indirect captures costs associated with an engineering firm providing construction management and biological monitoring, as well as post construction monitoring, as needed, associated with the surrender scenario. For the non-power scenario, 10% of the construction subtotal was applied and assumes no biological monitoring or post construction monitoring activities would be required. For the partial and full removal scenarios, 2% of the construction subtotal (less contaminated sediment disposal due to its volatility of occurrence and price) were applied. These costs may be variable as the design develops and permit stipulations are identified.

Contingency

A contingency of 10% was applied on the subtotal of work (excluding project indirect costs) based on the scale and class of the cost estimate with the associated risks and uncertainties based on available (and lack of) data pertaining to sediments.

4.2.4 COST ESTIMATE RESULTS SUMMARY

The full conceptual decommissioning cost estimate for the subject site under each scenario is provided in Appendix A. Table 4.4 provides a summary of the total cost by category.

Table 4.22 Webber Dam Cost Estimate Results Summary

DESCRIPTION	NON-POWER OPERATION	PARTIAL REMOVAL	FULL REMOVAL
Utility Separation	-	$74,390	$74,395
Decommissioning and Demolition	$497,728	$12,342,410	$14,298,560
Abatement and Regulated Material Removal	-	$13,622,094	$13,622,094
Salvage	-	($59,129)	($59,129)
Environmental and Restoration	-	$17,683,734	$19,945,443
Subtotal	**$497,728**	**$43,663,499**	**$47,881,363**
Project Indirect	$400,401	$6,713,253	$7,177,915
Contingency Cost	$49,773	$4,366,350	$4,788,137
Total Project Cost	**$947,902**	**$54,743,102**	**$59,847,415**

Note: Variation between totals in the estimates shown in this report and the April 2024 Road Map are due to the following:

1. Leave Powerhouse Intact was not included in the summation of the subtotal from the Non-Power Operation in the 2023 Hydropower Roadmap estimate.
2. Rounding of quantities to the next whole integer were applied in the estimates herein.
3. Verifications of quantity by unit price to equate to WSP Opinion of Costs, rounded to the next whole dollar were applied in the estimates herein.

APPENDIX

A WEBBER DAM HYDROELECTRIC PLANT CONCEPTUAL DEMOLITION COST ESTIMATE

A-1 WEBBER DAM SITE SUMMARY

Site Characteristics

- Two, 32-foot-high earth embankment dam sections, each with a concrete core wall and totaling 730 feet in length.
- A 33-foot-high concrete spillway with ten steel radial gates and a fixed-crest overflow section which discharge to a concrete apron extending approximately 105 feet downstream.
- A reservoir with a normal surface area of 660 acres at elevation 684.4 feet (U.S. Geological Survey [USGS] datum) and a gross storage of 6,000 acre-feet.
- A concrete and masonry powerhouse containing two generating units with a total installed capacity of 3,250 kilowatts (kW).
- A 186-foot-long concrete-lined tailrace with retaining walls and downstream weir.
- Associated appurtenant structures.
- Fish ladder owned and operated by Michigan DNR (not in FERC license)
- Canoe portage trail around west side of dam.
- One to two dozen private residences/docks on reservoir

Relicensing Issues

- Major license (referenced in License Order, subject to form L-3)
- Considerable fisheries resource issues
- Considerable Public Recreation Facilities
- Limited private property adjacent to shoreline

Future License Conditions

- Operations monitoring/automation
- Recreation monitoring or enhancements
- RTE and Wildlife Species Management Plans
- Invasive vegetation monitoring plan
- Fish stocking/funding
- Recreation enhancements (portage improvements, paddler trail opportunities)
- Land/Shoreline Management
- Historic Properties Management Plan
- Operational restrictions (run-of-river monitoring, seasonal shutdowns)
- Seasonal shutdown (April) for downstream salmonid smolt migration

Risks to Operating under another 50-year License

- Invasive fish passage if downstream barriers are removed
- Continued responsibility to meet regulatory requirements.
- Continued responsibility to operate and maintain the equipment, powerhouse, dam, and mitigation measures like recreation sites
- Unforeseen changes in restrictions in dam safety regulations/requirements

Condition Assessment Reports

POWERHOUSE

Based on the Technical Memorandum dated April 27, 2022, titled “Webber Hydroelectric Dam 2021 Powerhouse Condition Assessment Results Memo,” The exterior and interior powerhouse structure was given a 'Green' rating, indicating that that major repair will not be needed for about 10 to 20 years. While no immediate major repairs are required, additional maintenance and monitoring is recommended to prevent further need for repairs.

OTHER STRUCTURES

The Phase 2 (Visual and Non-Destructive Testing) condition assessment was completed by Golder on September 28 and 29, 2018 and consisted of the above-water concrete features/structures (Downstream Left Embankment Retaining Wall Segments 1 and 2, Downstream Powerhouse Piers, Downstream Right Embankment Retaining Wall, Downstream Spillway Apron (Exposed), Downstream Triangle, Fish Ladder, Fixed Crest Spillway, Left Wing Wall/Abutment, Right Wing Wall/Abutment, Spillway Abutment, Spillway, Piers, and Weir - Left

Segment and Right Segment, Training Wall Segments 1 and 2, Upstream Spillway Piers, Upstream Triangle).

The key findings from the Webber condition assessment identified one site feature (segment 2 of the training wall) that was rated as ORANGE (1 to 3 years before major repairs or replacement is necessary). One site feature (segment 1 of the training wall) was rated as BLUE (5 to 10 years before major repairs or replacement is necessary). Continued monitoring of segment 2 of the left embankment retaining wall is recommended to determine if the movement noted during the inspection is on-going. In addition, periodic maintenance including cleaning and sealing of the joints in the downstream left embankment retaining wall, fixed crest spillway and between the spillway abutment and left embankment retaining wall is recommended. Other structures that were inspected during this condition assessment and are included in this report were given a Green rating (10 to 20 years before major repairs or replacement is necessary).

DIVE INSPECTIONS

- July 20-21 and September 28, 2022:
    - The underwater portions of the Webber Hydroelectric Dam were in overall good condition. All features/structures were given a green rating, indicating that that major repair will not be needed for about 10 to 20 years. Deficiencies were limited to spalling, concrete aggregate pop-outs, minor to moderate cracking, surface scaling/erosion, and concrete surface flaking.
    - Additional underwater monitoring is recommended every 5 years. Continued removal of debris from the upstream powerhouse trash racks and spillway is also recommended.

FERC Part 12 Process

COMPREHENSIVE ASSESSMENT VS. PERIODIC INSPECTION – IMPACT ON COSTS:

The new Part 12 process replaces a program that previously included one type of inspection being performed on a five-year cycle. The new Part 12 process now includes two types of inspections, alternating on the same 5-year cycle. The first type, called a Periodic Inspection (PI), is described by FERC as a "performance-focused" inspection of project features. The second type, called a Comprehensive Assessment (CA), is described by FERC as a "deep dive" into the project with a project team of experts participating as part of the process. While FERC has generically stated that the CA will be more involved than the traditional Part 12 process, we have reason to expect that Owners may have to spend $250k to $500k to conduct a comprehensive assessment.

CURRENT PART 12 RECOMMENDATIONS:

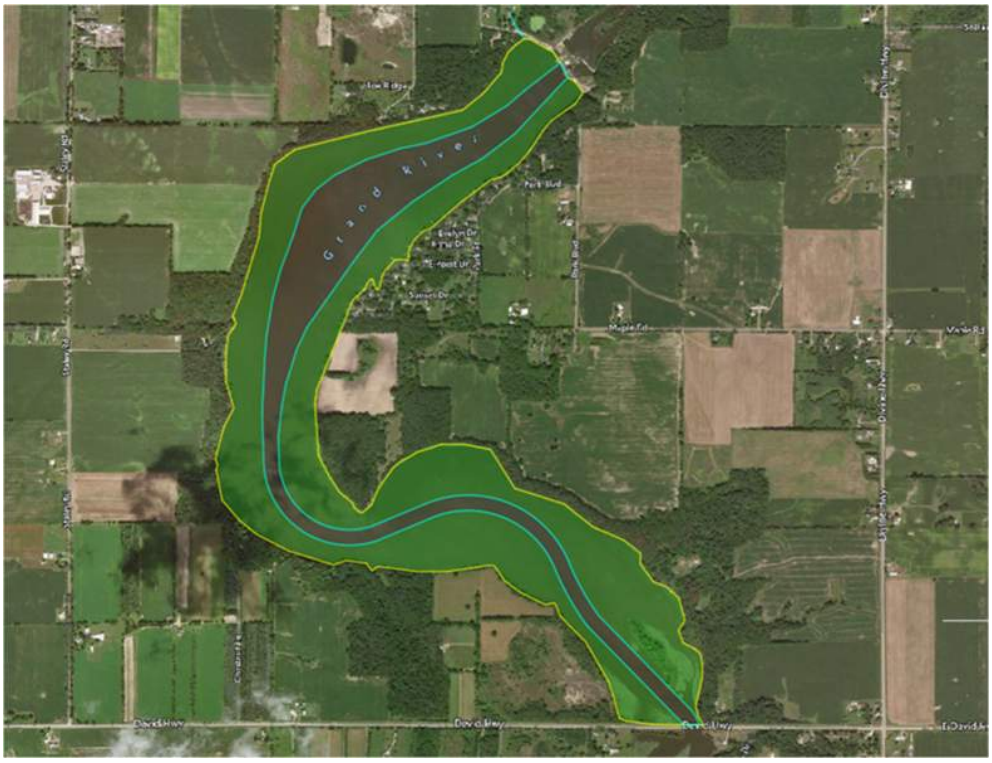
Based on a review of recommendations in the most recent Part 12 Report, most recommended repairs and/or studies are minor in nature and will not require as significant amount of capital to implement. The exception to this is the potential for repair of the tumble bay slab pending the study to determine the mechanism causing voids.

Current Remediation Projects in LTFP

- Unit 1 Overhaul and Generator Rewind – Capital
- Left Downstream Spillway Abutment Wall Replacement – Capital

- Unit 2 2400V Switchgear Replacement – Capital
- Unit 1 Concrete Repairs – O&M

Remediation Projects not in LTFP

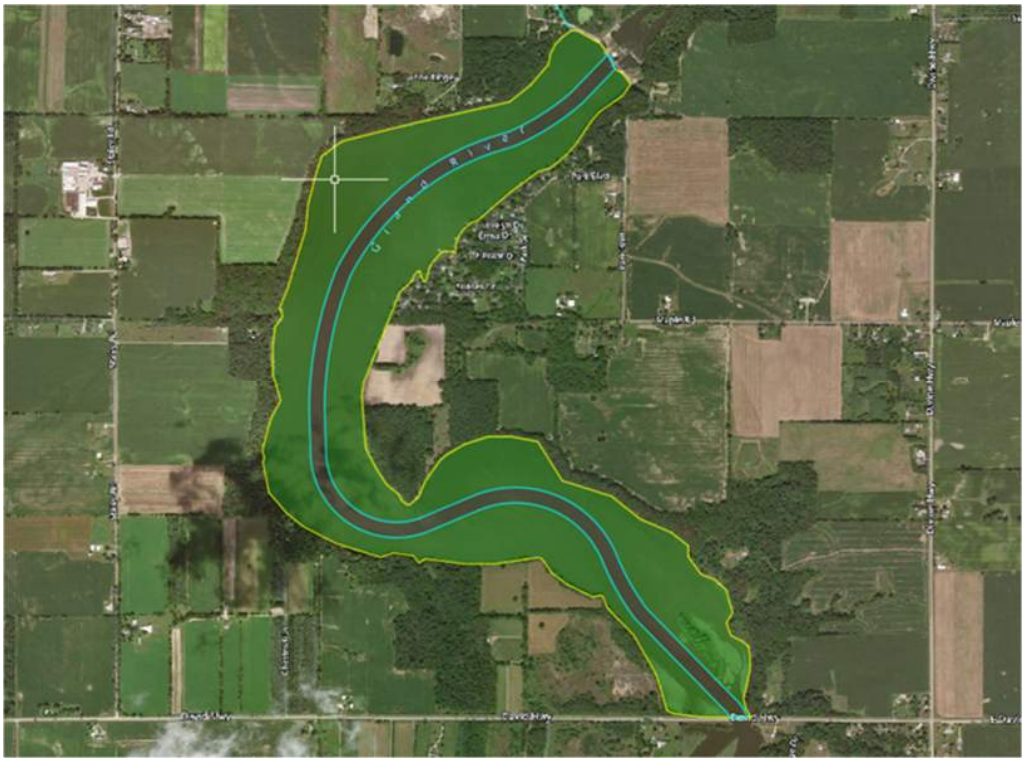


- Upstream Triangle Concrete Wall Remediation
- Right Embankment Toe Seepage Repair
- Core Wall Extension
- Unit 2 Bolt Replacement
- Draft Tube Concrete Repairs
- Downstream Powerhouse Pier Concrete Repairs
- Unit 2 Concrete Repairs

Generation

The Webber development consists of 2 units with a calculated maximum generation capacity of 37,668 MWH. Based on the Hydro Optimization report dated June 30, 2020, the average annual generation from 2011 to 2019 was 11,271 MWH, contributing 3% of the total generation from all 13 dam sites. With remediation, the average annual generation can be increased to 18,900 MWH.

Surrendering (projected to 2041 at end of licensing period and following FERC decommissioning process)



Decommissioning (Partial)

- Pros
  - Reduces legal liability and maintenance of existing facilities.
  - Fish ladder already installed.
  - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.
- Cons/Risks
  - This option will require significant coordination with regulatory agencies and external stakeholders due to changes in land use, majority of surrounding property is residential
  - New fish passage installation required.
  - May also still cause sediment transport issues.
  - Public disapproval of this option due to its socioeconomic and recreational impact (does not solve issue of poo portage for anglers and recreational boaters and paddlers).

- May serve as sea lamprey barrier with recent removal of Lyons Dam and potential removal of the partially failed Wager Dam downstream.
- Endangered unionid mussels at dam impoundment and tailwaters may be impacted by dam removal.
- Sediment release from removal may impact restoration conducted for Lyons Dam removal and potential Wager Dam removal downstream
- Impoundment may buffer water quality impacts associated with extensive upstream development, agriculture, septic issues, and point sources.
    - Potential for contaminated sediment removal and disposal will add significant cost burden.
- Consumers is evaluating the installation of a 6 FT weir as part of the partial removal option in order to maintain a portion of the reservoir for recreational use. It is WSP's opinion that under present day Michigan law, such a dam structure would be classified as having a LOW HAZARD POTENTIAL because its failure may cause damage limited to isolated inhabited homes, agricultural buildings, structures, secondary highways, short line railroads, or public utilities, where environmental degradation may be significant, or where danger to individuals exists.

Decommissioning (Full)

- Pros
    - Eliminates legal liability and maintenance of existing facilities.
    - Fish ladder already installed.
    - Mitigates many of the regulatory requirements associated with existing spillway & reservoir.

  - Eliminates responsibility to maintain and operate the powerhouse and aging dam and other associated structures.
  - Habitat can be restored along the entire footprint of the dam.
  - Eliminates sediment transport issues
  - Improved portage for anglers and recreational boaters and paddlers. A new boat launch downstream of Webber Dam is desired by the community now that the downstream Lyons Dam has been removed, but full removal of Webber may solve this issue.
- Cons/Risks
  - Significant coordination with regulatory agencies and external stake holders on potential changes in land use, riparian ownership, and aquatic habitat within the reservoir.
  - Public disapproval of this option due to its socioeconomic and recreational impact.
  - May serve as sea lamprey barrier with recent removal of Lyons Dam and potential removal of the partially failed Wager Dam downstream.
  - Endangered unionid mussels at dam impoundment and tailwaters may be impacted by dam removal.
  - Sediment release from removal may impact restoration conducted for Lyons Dam removal and potential Wager Dam removal downstream
  - Impoundment may buffer water quality impacts associated with extensive upstream development, agriculture, septic issues, and point sources.
    - Potential for contaminated sediment removal and disposal will add significant cost burden.

License Surrendering (Non-Power Operation)

- Pros
  - Lower initial cost burden
  - Maintain existing reservoir for recreational use. This option will likely be associated with the least public resistance as it will have the least immediate socioeconomic and recreational impact.
  - Contaminated sediments do not need to be removed and transported offsite.
  - Fish ladder already installed.
  - No disturbance to endangered unionid mussels found in dam impoundment and tailwaters.
  - Serves as sea lamprey barrier if partially failing Wager Dam is removed downstream.
- Cons/Risks
  - Legal liability associated with facilities and equipment surrendered in place. The dam structure and spillway will need to comply with all current and future FERC regulations that are required for surrender.
    - Future repairs to dam structure.
  - Transport of sediment and woody debris is also not improved through this option.

Divesting

Relicensing decision is further out than the Au Sable, Manistee, and Muskegon River projects. Putting this project on the market as part of a large portfolio is a near term action that can inform the next decisions. There is time before having to make a decision on relicensing or surrender.

A-2 WEBBER DAM NO-POWER GENERATION SCENARIO CONCEPTUAL ESTIMATE

Comsumers Hydropower
Webber Dam
Decommissioning Cost Evaluation

Category	Cost Activity	WSP Unit Cost	Quantity	WSP Opinion of Cost
Decommisioning and Demolition	Leave powerhouse intact	$ 320,606.00	1	$ 320,606.00
	Remove or lay up equipment	$ 88,564.00	1	$ 88,564.00

STATE OF MICHIGAN

BEFORE THE MICHIGAN PUBLIC SERVICE COMMISSION

In the matter of the application of **CONSUMERS ENERGY COMPANY** for approval of the sale of its River Hydroelectric Generating Fleet, related Power Purchase Agreement, and other Relief	)	Case No. U-21985

DIRECT TESTIMONY

OF

JASON R. COKER

ON BEHALF OF

CONSUMERS ENERGY COMPANY

October 2025

INTRODUCTION

Q. Please state your name and business address.

A. My name is Jason R. Coker, and my business address is One Energy Plaza, Jackson, Michigan 49201.

Q. By whom are you employed and in what capacity?

A. I am employed by Consumers Energy Company ("Consumers Energy" or the "Company") as the Director of Regulatory Policy and Research.

Q. Please describe your educational background.

A. I graduated from Western Michigan University in 1999 with a Bachelor of Business Administration Degree, majoring in accounting. I am also a Certified Public Accountant registered in the state of Michigan.

Q. Please describe your professional experience.

A. From 1999 to 2003, I worked as a staff auditor at Willis and Jurasek, PC in Jackson, Michigan where I conducted financial audits and prepared income tax returns. In 2003, I became the Director of Accounting for Delhi Charter Township in Holt, Michigan, overseeing payroll, accounts payable, accounting, financial reporting, and budgeting.

In 2005, I joined Consumers Energy as a General Accounting Analyst II in the Technical Accounting and Accounting Policy Department. My responsibilities included implementing new financial accounting standards, researching technical accounting issues, and reviewing contracts for accounting implications. In 2009, I was promoted to Senior Accounting Analyst and assumed responsibility for restricted stock accounting and certain Securities and Exchange Commission reporting disclosures, while continuing my previous duties. In 2012, I assumed responsibility for accounting and reporting of contingencies, including those related to Consumers Energy's manufactured gas plants.

In 2016, I joined the Rates and Regulation Department as a Senior Rate Analyst II in the Revenue Requirement Section and was promoted to Principal Rate Analyst in 2018. My responsibilities included developing, analyzing, and reviewing the Company's monthly return studies. These include studies pertaining to balance sheet working capital, cost of capital, return on investment, and Return on Equity ("ROE"). I also assisted in the development of analyses related to the Company's revenue requirements and the preparation of electric and gas rate case filings at the Michigan Public Service Commission ("MPSC" or the "Commission"). Additionally, I calculated the monthly Gas Cost Recovery ("GCR") factor and conducted various ad hoc studies pertaining to cost of capital, ROE, and revenue requirements. I was promoted to Director of Regulatory Policy and Research in 2024.

Q. What are your responsibilities as the Director of Regulatory Policy and Research at Consumers Energy?

A. As the Director of Regulatory Policy and Research, I lead the development and analysis of regulatory strategies that support the Company's electric and gas operations. My responsibilities include overseeing policy research, regulatory filings, and coordinating with internal subject matter experts to ensure our positions are well-supported and aligned with applicable regulatory frameworks. I also work closely with regulatory agencies, stakeholders, and industry groups to advocate for policies that promote reliability, affordability, and sustainability for customers.

Q. Have you previously filed testimony with the Commission?

A. Yes.

Q. Please state the proceedings you have been involved in.

A. I sponsored testimony in the following cases:

Case No. 17943-R – Consumers Energy GCR reconciliation case;

Case No. U-18166 – Consumers Energy Saginaw Trail Pipeline Act 9 Filing;

Case No. U-18322 – Consumers Energy electric rate case;

Case No. U-18411 – Consumers Energy GCR plan case;

Case No. U-18424 – Consumers Energy gas rate case;

Case No. U-20075 – Consumers Energy GCR reconciliation case;

Case No. U-20209 – Consumers Energy GCR reconciliation case;

Case No. U-20233 – Consumers Energy GCR plan case;

Case No. U-20234 – Consumers Energy GCR reconciliation case;

Case No. U-20322 – Consumers Energy gas rate case;

Case No. U-20650 – Consumers Energy gas rate case;

Case No. U-20963 – Consumers Energy electric rate case;

Case No. U-21090 – Consumers Energy 2021 integrated resource plan;

Case No. U-21224 – Consumers Energy electric rate case; and

Case No. U-21389 – Consumers Energy electric rate case.

Q. What is the purpose of your direct testimony in this proceeding?

A. The purpose of my direct testimony is to present the proposed accounting entries showing the effect of the proposed sale of Consumers Energy's 13 river hydroelectric generating plants ("River Hydros") and present the Company's proposed treatment of transaction costs, retention costs, and the gain on the sale of the River Hydros. My testimony will also

discuss the financial compensation mechanism ("FCM") associated with the power purchase agreement ("PPA").

Q. Are you sponsoring any exhibits in this proceeding?

A. Yes. I am sponsoring the following exhibits:

Exhibit A-10 (JRC-1) Projected Revenue Requirement

Exhibit A-11 (JRC-2) Projected Customer Rate Impacts

Q. Were these exhibits prepared by you or under your direction and supervision?

A. Yes.

Q. Please provide the name and principal business address of the applicant.

A. The applicant is: Consumers Energy Company, One Energy Plaza, Jackson, Michigan 49201.

Q. Please provide the name and address of the persons authorized to receive notices and communications regarding this application.

A. Notices and communications regarding this Application should be sent to the following Consumers Energy employees:

Jason R. Coker
One Energy Plaza
Jackson, Michigan 49201
(517) 474-2265 (phone)

jason.coker@cmsenergy.com

Bret A. Totoraitis

(517) 788-0835 (phone)
(517) 788-2470 (fax)
bret.totoraitis@cmsenergy.com

ACCOUNTING ENTRIES AND PROPOSALS

Q. Please summarize the main components of the transaction that are relevant to the transaction related accounting entries.

A. Consumers Energy has entered into an agreement to sell its 13 River Hydros (collectively the "River Hydro Fleet") to Confluence Hydro LLC ("Confluence") for a nominal price of

$1 per facility ("the hydro sale"). As part of the transaction, Consumers Energy will also enter into a 30-year Power Purchase Agreement ("PPA") with Confluence to purchase the electric output from the River Hydro Fleet.

The Company also purchased five properties downstream from Rogers Dam, in order to eliminate the need for the Rogers Spillway Project—resulting in an estimated $130 million in customer savings. The Plant in Service balance includes the costs associated with the acquisition of those properties and related demolition costs.

Company witness Richard T. Blumenstock provides additional details regarding the transaction in his direct testimony.

Q. What are the anticipated projected balances of the River Hydro Fleet-related accounts at the time of closing?

A. The Company assumed a closing date of March 31, 2027, for purposes of illustrating the proposed journal entries, based on the estimated timing of regulatory approvals. The projected balances were determined based on the actual net book value as of August 31, 2025, adding the incremental capital expenditures necessary for safe and reliable operations, and subtracting depreciation that is expected to be recovered through customer rates through March 31, 2027. This results in a projected net book value of the River Hydro Fleet of negative $28,900,000, i.e. the depreciation collected, including cost of removal, exceeded the total of capital investments in the plant. The projected balances at that time are provided in the following table.

Account Name	**A/C #**	**Debit Balance**	**Credit Balance**
Accumulated depreciation	108		443,700,000
CWIP	107	132,700,000	
Plant in Service	101	282,100,000	

These balances also serve as the Company's pro forma financial statements to reflect the impact of the transaction. Aside from the entries shown above, there are no other material impacts to the Company's financial statements resulting from the transaction.

Q. What accounting entry does the Company propose to record at the time of closing?

A. The Company proposes to record the following journal entry at the time of closing. The amounts of the journal entry are projected assuming a closing date of March 31, 2027. The actual journal entry amounts will likely vary due to the timing of regulatory approvals, actual transaction costs incurred, variances in maintenance costs, etc.

Account Name	**A/C #**	**DR**	**CR**
To record the proceeds from the sale			
Account Receivable	143	13	
Electric Plant Purchased or Sold	102		13
To remove original cost of plant at the time of sale closing (shown as 3/31/2027)			
CWIP	107		132,700,000
Plant in Service	101		282,100,000
Accumulated depreciation	108	414,800,000	
To remove the depreciation reserve for the assets at time of sale closing (show as 3/31/2027)			
Accumulated depreciation	108	443,700,000	
Electric Plant Purchased or Sold	102		443,700,000

To record gain on sale			
Gain on disposition of property	421.1		28,900,013
Electric Plant Purchased or Sold	102	28,900,013	
To record selling expenses to net with gain			
Gain on disposition of property	421.1	7,613,000	
Accumulated depreciation	108		7,613,000
To defer gain on sale for future refund			
Regulatory liabilities	254		21,287,013
Other income and deductions	426.5	21,287,013	

Q. How were the projected amounts of the journal entry determined?

A. The projected amounts were determined based on the projected net book value as described previously in this testimony. The projected net book value of the River Hydro Fleet of negative $28,900,000 will be removed from the Company's balance sheet. A receivable of $13 will be recorded for the nominal purchase price. The projected gain of $21,287,013 reflects the difference between the projected net book value of the River Hydro Fleet and the nominal purchase price, adjusted for estimated transaction costs of $7,613,000. The Company projects a net gain but acknowledges that unforeseen events and timing could cause the outcome of the transaction to result in either a net gain or a net loss and commits to transparently reporting the result once known.

Q. What does the Company propose to do with the gain on the transaction?

A. The Company proposes to defer the gain in a regulatory account for refund to customers. Should the outcome of the transaction result in a net loss, the Company proposes to defer the loss in a regulatory account. The method of recovery of any deferred loss would then be requested in the first electric rate case after the closing of the transaction.

Q. Does the Company have any additional accounting requests?

A. Yes. The Company has accounting requests for the following items related to the transaction: employee retention costs, incremental employee costs, and depreciation expense.

Q. What is the Company's proposal regarding employee retention costs related to the transaction?

A. The Company proposes to defer the employee retention costs of $14.5 million in a regulatory account. These employee retention costs are supported in the testimony of Company witness Adam J. Monroe. The Company further requests to net these costs against the deferred gain on the sale. The method of recovery of this net deferred balance would then be requested in the first electric rate case after the closing of the transaction.

Q. What are the incremental employee costs?

A. The incremental employee costs reflect the costs of onboarding additional employees to allow for adequate training ahead of the hydro sale closing. These are operational costs the Company will incur to support continuity of operations before and after the sale. Company witness Monroe provides additional details regarding the incremental employee costs in his direct testimony.

Q. What is the Company's proposal regarding the incremental employee costs related to the transaction?

A. The Company proposes to defer the incremental employee costs in a regulatory account. These incremental employee costs are expected to be approximately $4.9 million and are supported in the testimony of Company witness Monroe. The Company further requests to net these costs against the deferred gain on the sale. The method of recovery of this net deferred balance would then be requested in the first electric rate case after the closing of the transaction.

Q. Please summarize instances where the applicant, or any party to the transaction, intends to seek rate recovery of transaction costs, acquisition premiums, goodwill, or control premiums, and if so, what are the projected amounts?

A. The Company anticipates incurring approximately $27 million in transaction-related costs, including $14.5 million in employee retention costs, $4.9 million in incremental employee costs, and $7.6 million in legal and engineering expenses. As described above, the Company seeks regulatory approval to defer the retention costs and incremental employee costs and net them against the gain on the sale and include the net deferred balance in its next electric rate case. The legal and engineering costs are included in the calculation of the gain on the transaction.

There are no acquisition premiums, goodwill, or control premiums associated with this transaction.

Q. What is the Company's proposal regarding depreciation expense on the River Hydro Fleet?

A. If depreciation continues to be collected in rates after regulatory approvals are received, the Company proposes to record any over-collection as a regulatory liability, to be refunded to customers. The refund of any deferred amounts would be addressed in a future electric rate case.

Q. Is Consumers Energy making any additional commitments to the Commission that are not included in the transaction documents.

A. Yes, the Company is committing to refunding any net gain, if one is realized, from the transaction to customers, net of employee retention and incremental employee costs, as detailed earlier in this section of my testimony. Additionally, the Company will defer and subsequently refund to customers any depreciation expense collected in rates following regulatory approval of the sale.

Q. Are there any transaction-related savings credits being provided to customers?

A. While the transaction documents do not identify transaction-related savings credits, the Company is committing to refunding the net gain, if any, from the transaction, after accounting for employee retention and incremental employee costs, and will also refund any depreciation collected in rates after regulatory approval of the sale, as described previously. These could be regarded as transaction-related savings credits.

FINANCIAL COMPENSATION MECHANISM

Q. Do the proposed PPAs qualify for an FCM under MCL 460.6t(15) and MCL 460.1028(8)?

A. Yes. MCL 460.6t(15) provides that the Commission "shall authorize a financial incentive" for a PPA "with an entity that is not affiliated with that utility" when the PPA is for

"renewable energy resources or a third-party contract for energy storage systems or clean energy systems." MCL 460.1028(8) includes identical language. Confluence is an entity that is not affiliated with Consumers Energy. Furthermore, the River Hydro Fleet qualifies as "renewable energy resources" because (i) they are resources that naturally replenish over a human, not a geological, time frame and that are ultimately derived from water power and (ii) they produce electricity by converting the kinetic energy of moving water released through dams.

Q. How is the proposed FCM calculated?

A. The proposed FCM is calculated as the product of contract payments in each year multiplied by the Company's pretax weighted average cost of permanent capital comprised of long-term debt obligations and equity of the Company's total capital structure as determined by the Commission's final order in the Company's most recent electric general rate case. Specifically, the Company proposes an FCM initially based on a pre-tax weighted average cost of permanent capital of 8.75%, consistent with the weighted average cost of capital approved in Case No. U-21585 or such other pre-tax weighted average cost of permanent capital as may be in effect as the result of a final order in a subsequent Consumers Energy electric rate case at the time of the Commission's final order in this proceeding.

Q. What relief is Consumers Energy requesting from the Commission?

A. Consumers Energy respectfully requests that the Commission recognize that the PPA is eligible for an FCM in its final order in this case, consistent with MCL 460.6t(15) and MCL 460.1028(8).

INTERCONNECTION COSTS

Q. Does the Company expect to incur other costs related to the River Hydro Fleet?

A. Yes. The Company expects to incur approximately $20 million in interconnection costs to upgrade the substations serving the River Hydro Fleet. The units are grandfathered and have not been upgraded to modern interconnection standards. However, the Company has an obligation to perform these upgrades to mitigate the risk to public safety once these assets are turned over to a third party. The Company has eight years to complete the upgrades.

Q. What is the Company requesting regarding these interconnection costs?

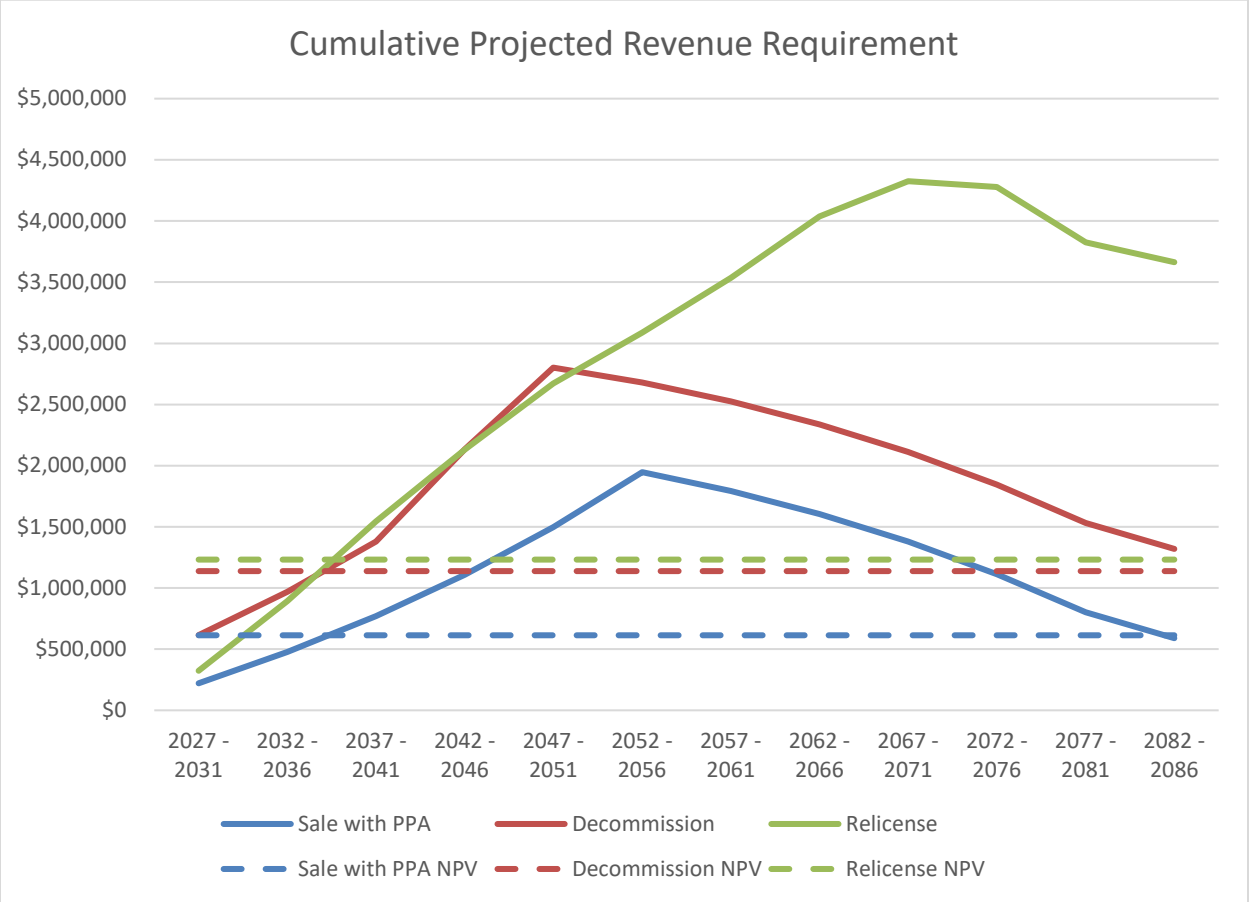
A. The Company intends to include these costs in future electric rate requests, as it would any other capital expenditure and recover them through base rates. The Company requests the Commission to determine that these future costs can be included in base rates, subject to a reasonableness and prudency review.

CUSTOMER IMPACTS

Q. Please explain Exhibit A-10 (JRC-1).

A. Exhibit A-10 (JRC-1) calculates the revenue requirement for the option to sell the River Hydro Fleet, the option to decommission the River Hydro Fleet, and the option to relicense and continue operating the River Hydro Fleet.

Lines 1 through 8 calculate the estimated revenue requirement of selling the River Hydro Fleet and entering into a PPA to purchase the electric output from the River Hydro Fleet. Line 2 calculates the impact of amortizing the projected net gain over the 30-year life of the PPA. Line 3 calculates the impact of the amortization of the deferred retention costs over the 30-year life of the PPA. Line 4 calculates the impact of the amortization of the deferred incremental employee costs over the 30-year life of the PPA. Line 5 shows



the costs of the PPA, which are supported by Company witness Blumenstock. Line 6 adds the cost to purchase replacement power. Line 7 reduces the revenue requirement for the market revenues associated with the power purchased. Line 8 is the revenue requirement associated with the sale of the River Hydro Fleet and is the sum of lines 2 through 6 less line 7.

Lines 9 through 28 show the calculation of the revenue requirement of decommissioning the hydro facilities at the end of their license periods. Lines 10 through 13 calculate the average plant balance for each year. Line 14 shows the depreciation rate that is necessary to fully depreciate the plant balance by 2050, the final year of decommissioning. Lines 15 through 19 calculate the average depreciation reserve for each year. Line 15 shows the beginning depreciation reserve for each year. Line 16 shows the depreciation expense, which is calculated by multiplying the average plant balance on line 13 by the depreciation rate on line 14. Line 17 shows the decommission spend or Cost of Removal, which is sponsored by Company witness Blumenstock. Line 18 is the ending depreciation reserve, which is calculated by adding lines 15 and 16 and subtracting line 17. Line 19 is the average depreciation reserve for the year which is calculated by dividing the sum of lines 15 and 18 by 2. Line 20 is the average rate base, which is calculated by summing lines 13 and 19. Line 22 calculates the return on rate base by multiplying line 20 by the weighted average cost of capital on line 21. Line 23 is the O&M expense, which is sponsored by Company witness Blumenstock. Line 24 is the depreciation expense from line 16. Property Taxes are shown on line 25. Replacement Power Cost is shown on line 26. Market Revenues are shown on line 27. The Revenue Requirement is shown on line 28. It is the sum of lines 22 through 26 less line 27.

Lines 29 through 47 show the calculation of the revenue requirement associated with the decision to relicense and continue operating the River Hydro Fleet. The calculation is similar to that of the decommissioning revenue requirement calculation.

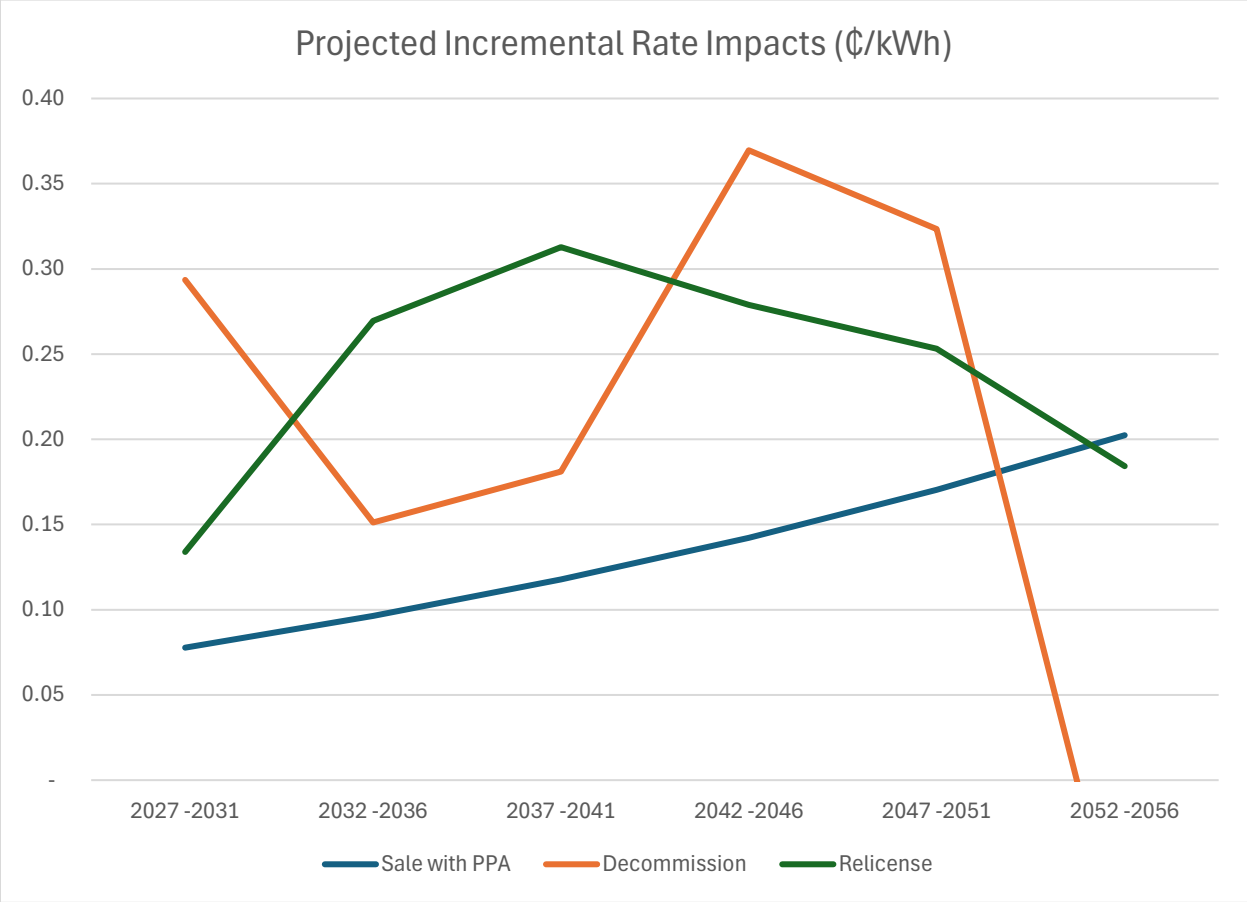
Q. Please describe the results of the revenue requirement calculations for the three options the Company considered.

A. The chart below presents the total revenue requirement for each scenario along with the net present values of those scenarios. It shows that the option to sell the River Hydro Fleet is the lowest cost option.

Q. Why did you include market revenue in your rate analysis when Mr. Blumenstock did not include it in his business case analysis?

A. Mr. Blumenstock's business case analysis did not include market revenue since it is equivalent in all scenarios and would have identical impacts on each business case. For further explanation, see the direct testimony of Company witness Blumenstock. My rate impact analysis includes market revenues since they will have an actual impact on electric rates.

Q. Please explain Exhibit A-11 (JRC-2).



A. Exhibit A-11 (JRC-2) calculates the impact to customer rates for the option to sell the River Hydro Fleet, the option to decommission the River Hydro Fleet, and the option to relicense and continue operating the River Hydro Fleet. Lines 1 through 12 calculate the customer rate impact of the three options by dividing the revenue requirement calculated on Exhibit A-10 (JRC-1) by projected total mega-watt hours sold. Lines 14 through 18 show the revenue requirements of the three options and amounts approved in rates in Case No. U-21585 for the River Hydro Fleet by five-year periods. Lines 19 through 23 show the cumulative revenue requirements for the three options plus the amounts included in rates per the order in Case No. U-21389 by five-year periods. Lines 24 through 27 show the net present value of each of the three options. Line 28 shows the projected sales in megawatt hours by five-year periods. Lines 29 through 32 calculate the customer rate impact by five-year period in cents per kilowatt hour. Lines 33 through 36 calculate the incremental customer rate impact by five-year periods by subtracting the revenue requirement approved in rates on line 18 from the revenue requirement of the options shown on lines 15 through 17 and then dividing the result by the projected sales on line 28. Lines 37 through 40

calculate the differences between the customer impacts of the various options.

Q. Please describe the projected impact of the transaction on customer rates.

A. The chart below provides a visual summary of the projected impact on customer rates. The option to sell the River Hydro Fleet and enter into a PPA with Confluence shows incremental rate impacts between 0.08 ¢/kWh and 0.20 ¢/kWh over the 30-year term of the PPA. The option to decommission the River Hydro Fleet shows incremental rate impacts between 0.15 ¢/kWh and 0.37 ¢/kWh over the 30-year term of the PPA. Beginning around 2051, the option to decommission would result in a reduction to customer rates due to the plants being fully decommissioned and the removal of depreciation expense for the River Hydro Fleet from the revenue requirement. The option to relicense the River Hydro Fleet shows incremental rate impacts between 0.13 ¢/kWh and 0.31¢/kWh over the 30-year term of the PPA. Selling the River Hydro Fleet has favorable customer rate impacts when compared with decommissioning and relicensing the River Hydro Fleet. The savings for customers when comparing selling the River Hydro Fleet with decommissioning range from 0.05 ¢/kWh in the 2032 - 2036 period to 0.23 ¢/kWh in the 2042 - 2046 period. Decommissioning the River Hydro Fleet would briefly have positive customer rate impacts between 2051, when the River Hydro Fleet would be fully decommissioned, and 2056, when the PPA term would expire, but the savings in those years would not be enough to offset the substantially higher customer rate impacts in the preceding years. The incremental rate impacts to customers from selling the River Hydro Fleet, compared to relicensing, range from an increase of 0.08 ¢/kWh in the 2077–2081 period to a savings of 0.38 ¢/kWh in the 2062–2066 period. Over the next 30 years, the projected incremental impacts range from an increase of 0.02 ¢/kWh (2052–2056) to a savings of

0.19 ¢/kWh (2037–2041).

Q. Is this transaction in customers' best interests?

A. Yes. The Company has selected the lowest cost option for customers. The PPA will cost customers less than it would cost them if the Company were to decommission the plants at the end of the term of each facility's operating license and will also cost less than it would cost if the Company chose to relicense and continue operating the River Hydro Fleet.

CAPITAL STRUCTURE

Q. Will this transaction impair the jurisdictional regulated utility's ability to raise the necessary capital or to maintain a reasonable capital structure?

A. No, this transaction will not have any impact or impairment on the utility's ability to raise future capital or maintain a reasonable capital structure. The amount of capital necessary

to fulfill Consumers Energy's obligation in this transaction is not material to the overall capital structure. Accordingly, this transaction will also have no material impact on the Company's cost of capital.

Q. Please provide a description of any new entities created to facilitate the transaction.

A. Hull Street Energy created a wholly owned subsidiary, Confluence, LLC, to facilitate the transaction and to own and operate the River Hydro Fleet.

Q. Please provide a summary of the capital structure of all parties to the transaction prior to the closing of the transaction and after the closing of the transaction.

A. Consumers Energy is well capitalized prior to the closing of the transaction. This transaction will not have a significant impact on the capital structure of Consumers Energy. Consumers Energy's capital structure will not be materially impacted by the capital outlays required by this transaction.

Confluence is owned via a partnership structure, with Hull Street Energy Partners III, LP holding a 70.43% ownership share and HSE Confluence Hydro Parallel, LLC holding a 29.57% ownership share. Confluence has no preferred stock and no bonded indebtedness. Confluence will have the financial resources of the PPA payments available to complete necessary improvements and to operate the River Hydro Fleet.

STATE AND LOCAL TAX IMPACTS

Q. Please describe the effect of the transaction on the Company's state and local tax liability.

A. The proposed transaction should not have a material impact on the Company's state and local income tax liabilities, nor should it have a material impact on the Company's state and local non-income tax liabilities. Confluence will assume responsibility for all local property taxes associated with the divested properties at the closing date. The amount of

property taxes associated with the River Hydro Fleet is $2,459,390 as detailed in Schedule 8.4(b)(i)(C) of the PSA which is filed in this case as Confidential Exhibit A-1 (RTB-1).

CONCLUSION

Q. Please summarize your direct testimony.

A. In summary, the proposed sale of the River Hydro Fleet and the associated Power Purchase Agreement with Confluence Hydro LLC represent a prudent and customer-focused strategy. The transaction enables long-term cost savings, avoids significant capital expenditures, and ensures continued access to renewable energy resources.

Consumers Energy respectfully requests Commission approval of the sale and the PPA, including the FCM. Additionally, the Company seeks approval to include the cost of acquiring five properties downstream from the Rogers Dam in the calculation of the gain on the sale and authorization to offset the projected gain on the sale, including transaction costs, of approximately $21.3 million against employee retention costs of approximately $14.5 million and incremental employee costs of approximately $5 million, and to propose a method to recover the net balance in its next general electric rate case following the outcome of this case. Lastly, the Company requests to defer for future refund any depreciation expense collected in rates after regulatory approval of the sale. This approach ensures transparency and fairness in the treatment of transaction-related costs and benefits.

Q. Does this conclude your direct testimony?

A. Yes, it does.

STATE OF MICHIGAN

BEFORE THE MICHIGAN PUBLIC SERVICE COMMISSION

In the matter of the application of **CONSUMERS ENERGY COMPANY** for approval of the sale of its River Hydroelectric Generating Fleet, related Power Purchase Agreement, and other Relief	)	Case No. U-21985

DIRECT TESTIMONY

OF

ADAM J. MONROE

ON BEHALF OF

CONSUMERS ENERGY COMPANY

November 2025

Q. Please state your name and business address.

A. My name is Adam J. Monroe, and my business address is 330 Chestnut Street, Cadillac, Michigan 49601.

Q. By whom are you employed and in what capacity?

A. I am employed by Consumers Energy Company ("Consumers Energy" or the "Company") as the Executive Director of Hydro Generation.

Qualifications

Q. Please describe your educational background.

A. In 2006, I received a Bachelor of Science in Civil Engineering from Michigan Technological University. I have been a registered Professional Engineer in the state of Michigan since 2010.

Q. Please describe your business experience.

A. I began my employment with Consumers Energy in 2006 as an Engineering Services Engineer. In 2007, I accepted a position as the River Hydro Dam Safety Engineer and in 2012 I was promoted to River Hydro Chief Dam Safety Engineer. In 2018, my role was retitled to Chief Dam Safety Engineer and in 2021 I was promoted to my current position in which I am responsible for dam safety, management, and operation of Consumers Energy's hydroelectric plants.

Q. Have you previously provided testimony before the Michigan Public Service Commission ("MPSC" or the "Commission")?

A. Yes, I provided testimony in the following MPSC cases:

- Case No. U-21224: Application of Consumers Energy for authority to increase its rates for the generation and distribution of electricity and for other relief;

- Case No. U-21389: Application of Consumers Energy for authority to increase its rates for the generation and distribution of electricity and for other relief; and

- Case No. U-21585: Application of Consumers Energy for authority to increase its rates for the generation and distribution of electricity and for other relief.

Q. What is the purpose of your direct testimony in this proceeding?

A. The purpose of my direct testimony is to support the Company's request to sell its river hydro fleet ("the Facilities") to Confluence Hydro, LLC ("Confluence"), a subsidiary of Hull Street Energy ("Hull Street"). Consumers Energy will transfer the Facilities, including equipment and land, and associated liabilities, by entering into four primary agreements with Confluence: (i) the Purchase and Sale Agreement ("PSA"), the Environmental Indemnity Agreement ("EIA"), the Regulatory Disallowance Agreement ("RDA"), and the Power Purchase Agreement ("PPA"). All such agreements work together to effectuate the transaction.

My direct testimony will specifically:

- Explain the organization charts depicting the current and proposed post transaction corporate structures;

- Explain if there will be any labor force reductions associated with the transaction;

- Provide a description of any proposed safeguards for stabilizing wages and benefits associated with the transaction Bid development, stages, due diligence, negotiations;

- Explain the people that will be transitioning with the transaction;

- Explain whether the proposed action would have an adverse impact on the provision of safe energy service in this state; and

- Provide assessment of Hull Street's safety performance.

Q. Are you sponsoring any exhibits with your direct testimony?

A. No

Q. How are the following sections of your direct testimony organized?

A. My direct testimony is divided into two sections. Section I will describe organization structure and employee matters. Section II will describe the safe operation of the hydro fleet post close.

SECTION I

EMPLOYEE MATTERS

Q. The Facilities are currently operated within the River Hydro Organization of Consumers Energy. Please describe the organization structure of the River Hydro Organization prior to the sale of the Facilities to Confluence.

A. The River Hydro Organization currently consists of 59 core staff (salaried and union positions), which includes active vacancies. This staff is broken down into Operations and Maintenance, Engineering, Dam Safety, and Licensing, all reporting up through the Executive Director of Hydro Generation, which is my current role. The Executive Director of Hydro Generation reports to the Vice President of Generation Operations within Consumers Energy's Electric Supply Organization.

Q. Explain the breakdown between salaried and union positions within the River Hydro Organization.

A. There are a total of 27 salaried employees and 32 union employees within the River Hydro Organization. As noted above, this number includes current vacancies which may be backfilled prior to the closing of the sale.

Q. Please explain any changes to the corporate structure at Consumers Energy as a result of the sale.

A. The River Hydro Organization is part of Consumers Energy and is not an affiliate or subsidiary of Consumers Energy. Therefore, when the River Hydro Organization transitions to Confluence, there will be no changes to the Company's and/or CMS Energy's corporate structure.

Q. Please describe the organization structure for the River Hydro Organization post sale transition.

A. As part of the sale, the entire River Hydro Organization, including all 59 employee positions, will become part of Confluence. As explained above, Confluence is a wholly owned subsidiary of Hull Street and it is expected that, as part of the sale, Confluence will transfer each individual Facility into a wholly owned subsidiary of Confluence.

Q. Please describe if any employees will lose their job or be laid off due to the transaction.

A. There will be no labor reduction because of this transaction at Consumers Energy or within the River Hydro Organization. As part of the sale, each River Hydro Organization employee will be eligible to receive a job offer from Confluence to continue employment with Confluence on comparable terms. Since the terms of employment for the union River Hydro Organization are governed by a Working Agreement (i.e. collective bargaining agreement), those employees will have the option of: (i) transferring to Confluence Hydro or (ii) taking a different position at the Company.

Q. Please explain why it is important that Consumers Energy employee positions transition to Confluence as a part of the sale.

A. Consumers Energy and Confluence both recognize the importance of the people that safely operate, maintain, and support the 13 river hydros. While Confluence's parent, Hull Street, has extensive experience operating hydros, the transfer of the Company's employees to Confluence will further ensure that Confluence will have a world-class, efficient, and safe workforce on day one with the transition of staff. This helps ensure the operational excellence that has been instilled at these facilities over the past 100 years will be passed on to Confluence.

Q. Explain if all Consumers Energy River Hydro Employees will transition to Confluence Hydro at the time of closing the sale.

A. All salaried river hydro employee positions will transition to Confluence Hydro at the time of sale. The salaried employees will not have the option to stay at Consumers Energy. The union river hydro positions will also transition to Confluence Hydro at the time of sale, but, as explained above and in more detail below, per the Working Agreement, the employees in those positions will also have the option to be placed in a new position and remain a Consumers Energy employee.

Q. Explain if there are any additional employees that will transition to Confluence Hydro at the time of sale.

A. Yes, there are additional employees that will be hired into the river hydro organization to support the transition. This includes full-time Consumers Energy employees and contracted employees.

Q What are the incremental employee costs for the additional hydro staff?

A. The incremental employee costs reflect the costs of onboarding additional operation resources to allow for adequate training ahead of the hydro sale closing. These resources are expected to include up to 20 hydro operators at approximately $200K per year per person, six office workers at approximately $150K per year per person and two office workers at $200K per year per person. These are operational costs the Company will incur to support continuity of operations before and after the sale.

Q. What is the Company's proposal regarding the incremental employee costs related to the transaction?

A. The Company proposes to defer the incremental employee costs into a regulatory account. These incremental employee costs are expected to be approximately $4.9 million. The Company further requests to net these costs against the deferred gain on the sale. The method of recovery of this net deferred balance would then be requested in the first electric rate case after the closing of the transaction.

Q. Please explain why Union Employees will have the option to remain Consumers Energy Employees.

A. The Working Agreement between Consumers Energy and the Utility Workers Union of America and its Michigan State Utility Workers Council provides that represented employees have Article VII, Section 9 transfer rights through the final closing date of the sale and Article VII, Section 17 and Appendix 46 placement rights. Represented employees that stay at Consumers Energy post-closing of sale will be placed in a job within 60 miles of their headquarter location.

Q. Please provide a description of any proposed safeguards for stabilizing wages and benefits associated with the transaction.

A. The PSA, as provided in Exhibit A-1 (RTB-1), provides salary and benefits safeguards for the transferred employees to ensure that these employees can continue employment with Confluence on comparable employment terms. For the transferred salaried employees, these employees will receive comparable employment terms for a minimum of a year following sale closing. For the transferred union employees, these employees will continue employment pursuant to the terms of the Working Agreement, which Confluence has agreed to be bound by and assume as part of the sale.

Q. Please explain if there are any agreements in place to ensure employees remain at the Facilities to ensure adequate staffing for safe operation until the closing of the transaction.

A. Yes, to ensure necessary staffing at the Facilities through the closing date, as well as the need to continue to ensure safe operation of the Facilities after the sale, Consumers Energy is providing River Hydro Organization employees with a retention incentive program which will be memorialized in retention agreements with each employee.

Q. Please explain the union employee retention agreement and separation payments.

A. The terms of the union retention agreement are as follows: (i) a bonus of 5% of annual base pay (as of the date the agreement is offered) in exchange for signing the Agreement within the agreed upon number of days of its offer; (ii) a bonus of 95% of annual base pay (as of the final closing of the sale date) if employee agrees to forfeit their Article VII, Section 9 transfer rights through the final closing date of the sale; and (iii) bonus of 50% of annual base pay (as of the final closing of the sale date) if the employee forfeits their Article VII,

Section 17 and Appendix 46 placement rights. These bonus options may be stacked – meaning an eligible employee is eligible to elect each of the three bonuses (totaling 150% of annual base pay). In addition, employees eligible for a pension, but under fifty-five (55) years of age, will receive a one-time payment for the early vesting of such pension and employees eligible for retiree healthcare will receive a one-time payment to supplement loss of such retiree healthcare. Union employees are also eligible for a separation payment per the working agreement.

Q. Please explain the salaried employee retention agreement and separation payments.

A. The salaried employee retention agreement includes: (i) a retention payment of 150% of annual base pay as of the final closing of the sale; (ii) employees eligible for a pension, but under fifty-five (55) years of age, will receive a one-time payment for the early vesting of such pension; (iii) employees eligible for retiree healthcare will receive a one-time payment to supplement loss of such retiree healthcare ; (iv) eligible employee will receive a one-time payment to supplement the loss of non-vested restricted stock; and (v) there is also a payment of 12 weeks of regular straight time pay plus an additional sum equal to one week of regular straight time pay for each complete year of service, up to a maximum of 26 weeks.

SECTION II

SAFETY PERFORMANCE

Q. Please explain whether the proposed action would have an adverse impact on the provision of safe energy service in this state.

A. There is no expected adverse safety impact as a result of this transaction. As a part of the Request for Proposal ("RFP") process, Consumers Energy evaluated potential buyers'

safety records. This included a review of whether the potential buyer had an Owners Dam Safety Program ("ODSP"), experience operating hydroelectric dams, their relationship with the Federal Energy Regulatory Commission ("FERC") and their compliance record with FERC license requirements. As a part of the evaluation, Hull Street supported the safety record and experience to operate the Facilities safely.

In addition, as explained above, Consumers Energy River Hydro Organization employee positions will transition to Confluence as a part of the sale. Confluence will have a world-class, efficient, and safe workforce on day one with the transition of staff. If the Union operations staff elects to stay at Consumers Energy, the Company intends to backfill operator positions in the interim period prior to the close date so that as many River Hydro Organization employees can transition as possible. Consumers Energy has an agreement with the union to hire river hydro operator staff that will not have contractual transfer or placement rights. Their positions will go with the sale of the dams. The plan is to hire these positions filled by January 2026 to ensure they have the proper time to be trained and certified on the operation. This plan will ensure the same operational excellence at the Facilities will continue after the sale closes.

Q. As set forth above, Hull Street is the parent company to Confluence. Please explain Hull Street's experience in safely operating hydroelectric dams.

A. Hull Street has a long track record of successfully owning and operating hydroelectric facilities across North America. This includes the acquisition and improvement of 47 hydro assets within the past decade. Hull Street currently owns one hydroelectric dam, Boott Hydro located in Lowell, Massachusetts. Hull Street maintains an ODSP for the facility and there have been no material dam safety incidents or license violations. In

addition, Hull Street's management team has significant history/experience with safely operating river hydro and other generation assets. Hull Street is also a member of the National Hydropower Association which keeps them informed of industry standards and best practices.

Q. What is the ODSP?

A. The ODSP is required for FERC-licensed hydroelectric facilities to ensure dam safety and compliance with FERC dam safety requirements. The ODSP is intended to ensure that employees, agents, and consultants have a complete understanding and a constant awareness of the need to fully comply with all necessary dam safety measures and requirements. Hull Street has an ODSP in place for its current hydroelectric facility.

Q. Describe FERC's regulation of the Facilities.

A. FERC comprehensively regulates the Facilities under Part I of the Federal Power Act and corresponding regulations. FERC's jurisdiction and authority includes dam safety, environmental protection, and operations. Each Facility is governed by the terms of its specific FERC project license and corresponding documents (e.g. Land Management Plans), which impose a variety of restrictions and obligations on the Company under federal law.

Q. Please describe the FERC regulation of the Facilities post-closing of the sale.

A. All 13 FERC licenses (i.e. one for each Facility) will be transferred to Confluence and will be valid through the end of the existing license period, most of which are set to expire in 2034. This includes all requirements in the FERC licenses for dam safety, operation, land management, and recreation. Confluence will assume all legal responsibility for the hydroelectric projects' condition and operation. Prior to the end of the existing license

period for the facilities, Confluence will be responsible for filing any license renewal applications with FERC for their continued operation.

Q. Please describe if FERC will have a review of Hull Street's safety record.

A. FERC will review Confluence's technical capabilities to operate the facility safely, as well as Confluence's financial ability to safely maintain their hydroelectric projects as a part of the FERC license transfer process. This review will include an assessment of Confluence's existing dam safety program, as well as Confluence's overall technical expertise to safely operate the facilities in accordance with the FERC licenses.

Q. Does this conclude your direct testimony?

A. Yes, it does.

STATE OF MICHIGAN

BEFORE THE MICHIGAN PUBLIC SERVICE COMMISSION

In the matter of the application of **CONSUMERS ENERGY COMPANY** for approval of the sale of its River Hydroelectric Generating Fleet, related Power Purchase Agreement, and other Relief	))))))	Case No. U-21985

DIRECT TESTIMONY

OF

ANGELA THOMPKINS

ON BEHALF OF

CONSUMERS ENERGY COMPANY

October 2025

Q. Please state your name and business address.

A. My name is Angela Thompkins and my business address is 1 Energy Plaza, Jackson, Michigan 49201

Q. By whom are you employed and in what capacity?

A. I am employed by Consumers Energy Company ("Consumers Energy" or the "Company") as the Vice President of Community and Media Relations and Chief Diversity Officer.

Qualifications

Q. Please describe your educational background.

A. In 1998 I received a Bachelor of Science degree from Eastern Michigan University; followed by a Juris Doctor from Thomas M. Cooley Law School in 2002; and an LL.M. in Labor and Employment Law in 2008 from Wayne State University Law School. I am also licensed to practice law in the state of Michigan.

Q. Please describe your business experience.

A. Prior to joining Consumers Energy I held a variety of roles in the legal, automotive, food service industries, and education. These roles included Prosecuting Attorney with the City of Detroit; Labor Relations with DaimlerChrysler, LLC: local and state lobbyist for Chrysler, LLC; Director of Fair Housing for Legal Aid and Defender, Detroit; Human Resources Manager at US Foodservice; and adjunct professor at Henry Ford Community College and Eastern Michigan University.

I began my employment with Consumers Energy in 2013 as a Human Resources Business Partner and held a variety of positions within the Company including: Manager, Diversity and Inclusion; Director of Diversity and Inclusion and Talent Acquisition; Executive Director of Diversity and Inclusion; Vice President and Chief Diversity Officer;

and my current role as Vice President of Community and Media Relations and Chief Diversity Officer.

Q. Please describe the role of the Community Engagement team.

A. The Consumers Energy Community Affairs team consists of 18 Community Affairs Managers across the Company's service territory. The Community Affairs Managers live within the geographical areas they represent. By living in the communities they serve, the Community Affairs Managers can identify and understand the unique needs of each community and provide equitable and sustainable solutions and help remove barriers to access. The team is responsible for building trusted and meaningful relationships with municipal leaders, community influencers, community organizations and serve as a liaison between the Company and the community. As the Company's voice within the communities, the Community Affairs Managers develop relationships to ensure all community groups and voices are heard and include but are not limited to ALICE populations, environmental justice communities, rural areas, and seniors.

Q. Have you previously provided testimony before the Michigan Public Service Commission ("MPSC" or the "Commission")?

A. Yes. I testified in the Company's Electric Rate Case, Case No. U-21585.

Q. What is the purpose of your direct testimony in this proceeding?

A. The purpose of my direct testimony is to support the Company's request to sell its river hydro fleet to Confluence Hydro, LLC ("Confluence"). Consumers Energy has agreed to sell the river hydro generation fleet assets and transfer the associated liabilities by entering into four agreements with Confluence, a fund company of Hull Street Energy. The Purchase and Sale Agreement, the Environmental Indemnity Agreement, the Regulatory

Disallowance Agreement, and the Power Purchase Agreement work together to effectuate the transaction. Toward that end I will explain the Company's two-year community engagement strategy with the communities surrounding the Company's river hydro assets to ensure all voices were heard and considered in the Company's decision making process.

Q. Are you sponsoring any exhibits with your direct testimony?

A. Yes, I am sponsoring the following exhibits:

Exhibit A-12 (AT-1)	Economic Impact Study for Alcona Dam;
Exhibit A-13 (AT-2)	Economic Impact Study for Calkins Bridge Dam;
Exhibit A-14 (AT-3)	Economic Impact Study for Cooke Dam;
Exhibit A-15 (AT-4)	Economic Impact Study for Croton Dam;
Exhibit A-16 (AT-5)	Economic Impact Study for Five Channels Dam;
Exhibit A-17 (AT-6)	Economic Impact Study for Foote Dam;
Exhibit A-18 (AT-7)	Economic Impact Study for Hardy Dam;
Exhibit A-19 (AT-8)	Economic Impact Study for Hodenpyl Dam;
Exhibit A-20 (AT-9)	Economic Impact Study for Loud Dam;
Exhibit A-21 (AT-10)	Economic Impact study for Mio Dam;
Exhibit A-22 (AT-11)	Economic Impact Study for Rogers Dam;
Exhibit A-23 (AT-12)	Economic Impact Study for Tippy Dam;
Exhibit A-24 (AT-13)	Economic Impact Study for Webber Dam; and
Exhibit A-25 (AT-14)	2024 Prosperity Group Final Report.

Q. Were these exhibits prepared by you or under your direction and supervision?

A. Exhibits A-12 (AT-1) through A-25 (AT-14) were extracted from Consumer's Energy's records kept in the ordinary course of business and are an accurate copy of that record.

SECTION I

COMMUNITY ENGAGEMENT STRATEGY

Q. How does Consumers Energy proactively engage communities?

A. Consumers Energy is deeply embedded in the communities it serves. The Consumers Energy Community Affairs team members serve on over 130 community boards. On those boards, the Company cultivates trusting relationships and leverages the opportunity to inform, educate, and engage with community leaders regarding issues and topics involving the Company and its customers. These memberships allow for two-way engagement with members in their respective communities.

Q. Please describe the Company's Community Engagement plan related to the request to sell the hydroelectric fleet to Confluence.

A. In early 2021, Consumers Energy began discussions about the future of its 13 hydroelectric dams located throughout the Lower Peninsula of Michigan. These discussions eventually led to an effort by Consumers Energy to make public its intent to decide on the future of these Facilities from three potential options. As part of the discussion and the plan to go public, it was determined there was a need for a comprehensive communications plan and a community engagement plan for each dam that would guide Consumers Energy in how it would interact with and work with each community regarding the three future options. Consumers Energy retained Public Sector Consultants ("PSC"), a Lansing-based nonpartisan research and leading consulting firm that specializes in public engagement, to help develop a community engagement plan and to lead community conversations to better understand the impact of Consumers Energy's hydro Facilities. The goal of the plan was to ensure Consumers Energy created an opportunity for all interested stakeholders to have

a voice in the process in a meaningful way. Consumers Energy committed to transparency throughout this process. As such, the Company, with assistance from PSC, developed "The Future of Hydroelectric in Michigan" website as a place to provide up-to-date information and details of the information provided at each community meeting. These stakeholder conversations began in 2022 and concluded in 2024 with a final report (Exhibit A-25 (AT-14)) that summarizes the input and feedback from each community.

SECTION II:

COMMUNITY ENGAGEMENT – YEAR ONE

Q. Please describe the Company's Community Engagement activities in 2022.

A. Consumers Energy and PSC met with and received detailed opinions and feedback from United States Forest Service, Great Lakes Fishery Commission, Michigan Department of Natural Resources, and the Michigan Hydro Relicensing Coalition. Additionally, Consumers Energy and PSC held public meetings at all 13 dams starting in late August and ending in mid-October. The 13 meetings were attended by approximately 1,700 people and Consumers Energy received approximately 570 comments via email and/or online. The key details provided at each meeting were:

- Overview of Consumers Energy Hydro Operations and key areas of importance such as safety, regulatory, environment and community;
- The disclosure and overview of the three future scenarios; and
- Timeline of Hydro Strategy.

PSC conducted property-owner surveys to residents within 100 feet of Consumers Energy's FERC boundary. 1,381 surveys were completed and returned resulting in a 60% return rate or 1,381 out of 2,312 landowners. At the request of the public and community leaders, Consumers Energy contracted with PSC to complete an economic contribution plan for

each dam as well as a statewide economic contribution analysis. (Exhibits A-12 (AT-1) through Exhibit A-24 (AT-13)).

Over year one, Consumers Energy held in-person public meetings for all 13 dams with a focus on providing an overview of Hydro Operations, the disclosure and overview of the three future scenarios, and an overall timeline for the future Hydro Strategy.

COMMUNITY ENGAGEMENT – YEAR TWO (2023)

Q. Please describe the Company's Community Engagement activities in 2023.

A. Consumers Energy and PSC created a community engagement plan to develop local prosperity groups where the dams are located as a means for getting more in-depth information about the local sentiment and needs for each of the potential options and included stakeholders who were both for and against the dams. The feedback from the prosperity groups would be used to inform and influence the Company's decision. Based on the number of inquiries about the option to sell all 13 hydro Facilities, Consumers Energy investigated the possibility of a sale as one of the options. Throughout 2023, the Company worked to develop a Request for Proposals ("RPFs") that would entice bids for the purpose of determining if sale was truly an option to be considered. In July, PSC completed economic contribution studies for all 13 hydro Facilities with the goal of determining the economic contribution these Facilities provide to the local economy. The data provided included the gross regional product, the number of jobs, and the amount of local, state, and federal tax effects from recreational and related spending at the Facilities. Consumers Energy and PSC held public meetings for all 13 dams but combined some dams into one meeting resulting in a total of 10 public meetings being held in person.

- The key details provided at the meetings were:
  - Overview of 2022 meetings;

- Overview of adjacent landowner and engagement survey, economic contribution study for that dam, and the statewide economic contribution analysis;
- Update on Hydro Strategy including the external funding options and the investigation into sale of the dams being a new option;
- Discussed Hydro impact on residential, business, and industrial customers; and
- Discussed the development of a community prosperity meeting for 2024.

Consumers Energy and PSC also held two virtual meetings. The meetings covered the same context as the individual hydro meetings, but with a more statewide focus and with a goal of reaching non-dam communities and stakeholders.

Over the course of year two Consumers Energy held 10 in-person public meetings and two virtual public meetings. The meetings focused on an overview of the 2022 public meetings, discussion on external funding options, the investigation into the sale of the dams, the impact to customers and the development of community prosperity groups. In addition, PSC completed a contribution study for each dam, a statewide economic contribution analysis, and community engagement report for each dam.

COMMUNITY ENGAGEMENT – YEAR THREE (2024)

Q. Please describe the Company's Community Engagement activities in 2024.

A. PSC completed economic impact studies for all 13 hydro Facilities with the goal of determining the impact a partial removal or full removal of the dam would have on the local economy. The data provided included the gross regional product, the number of jobs, and the amount of local, state, and federal tax effects from recreational and related spending at the Facilities. The resulting data for each dam reflects a significant negative impact. However, PSC observed that over the long term, recreational activity is likely to return.

Consumers Energy and PSC worked with the communities at the 13 dams to develop prosperity groups, organized by river:

- Au Sable River: Cooke, Foote, Loud and Five Channels dams
- Au Sable River: Mio dam
- Au Sable River: Alcon dam
- Muskegon River: Rogers, Croton and Hardy dams
- Manistee River: Hodenpyl and Tippy dams
- Kalamazoo River: Calkins Bridge dam
- Grand River: Webber dam

Four meetings were held with each prosperity group. Each meeting provided Consumers Energy with the ability to provide updates and answer questions regarding the Hydro Strategy. The key focus of each meeting was to present a question with a focus on the following:

- Meeting 1: What are the existing strengths/assets in the community?
- Meeting 2: Which strengths/assets can we build upon with the dam? Without the dam?
- Meeting 3: What is Consumers Energy's role in helping us reach the community's aspirations?
- Meeting 4: How will we reach our community's aspirations?

A final report was developed and provided to the public in December 2024. (Exhibit A-25 (AT-14)). Closing out 2024, Consumers Energy informed the prosperity groups that the Company was working through the RFPs received and determining which, if any, were viable potential buyers. Consumers Energy made a commitment to full transparency and stated that the Company would inform the prosperity groups once a decision was made.

COMMUNITY ENGAGEMENT – YEAR FOUR (2025)

Q. Please describe the Company's Community Engagement activities in 2025.

A. In April, PSC sent the prosperity groups an email providing an update on the Hardy Dam Spillway project and how Consumers Energy was implementing a temporary pause in construction due to the current RFP negotiations. In June, PSC sent an email to the prosperity groups providing an update on the RFP process stating that (i) Consumers Energy believed a sale of the dams to be the best path forward for customers and (ii) negotiations were in progress, although no final decision has been reached. In September, prior to a public announcement, Consumers Energy hosted a virtual meeting with all seven prosperity groups and informed the groups of the agreement with Confluence to buy all 13 dams. Throughout the remainder of the year, Consumers Energy plans to host in-person meetings with the communities to answer questions and introduce members of Confluence operations and leadership teams. Consumers Energy also plans to meet with each of the seven prosperity groups.

Q. Please describe Exhibit A-12 (AT-1) (Alcona).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Alcona Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Alcona Dam include:

- A reduction of $1 million in gross regional product and 41 jobs; and
- A reduction of $376,041 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

Q. Please describe Exhibit A-13 (AT-2) (Calkins).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Calkins Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Calkins Dam include:

- A reduction of $2.9 million in gross regional product and 41 jobs; and
- A reduction of $587,668 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

The partial removal of the dam would also impact adjacent property values, including:

- A reduction of $24.5 million in market value to adjacent properties; and
- A reduction of $389,643 in local and state property tax revenue due to the decreased market value.

The full removal of the dam would also impact adjacent property values, including:

- A reduction of $35.6 million in market value to adjacent properties; and
- A reduction of $507,303 in local and state property tax revenue due to the decreased market value.

Q. Please describe Exhibit A-14 (AT-3) (Cooke).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Cooke Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Cooke Dam include:

- A reduction of $1.3 million in gross regional product and 40 jobs; and
- A reduction of $423,383 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

Q. Please describe Exhibit A-15 (AT-4) (Croton).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Croton Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Croton Dam include:

- A reduction of $629,499 in gross regional product and 15 jobs;
- A reduction of $187,095 in local, county, state, and federal taxes through direct, indirect, and induced; and
- Tax effects from recreational spending.

The partial or full removal of the dam would also impact adjacent property values, including:

- A reduction of $25.3 million in market value to adjacent properties; and
- A reduction of about $372,837 in local and state property tax revenue due to the decreased market value.

Q. Please describe Exhibit A-16 (AT-5) (Five Channels).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Five Channels Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Five Channels Dam include:

- A reduction of 92,476in gross regional product and 3 jobs; and
- A reduction of $29,183 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

Q. Please describe Exhibit A-17 (AT-6) (Foote).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Foote Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Foote Dam include:

- A reduction of $4.7 million in gross regional product and 151 jobs; and
- A reduction of $1.6 million in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

Q. Please describe Exhibit A-18 (AT-7) (Hardy).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Hardy Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Hardy Dam include:

- A reduction of $10.7 million in gross regional product and 251 jobs; and
- A reduction of $3.1 million in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

The partial or full removal of the dam would also impact adjacent property values, including:

- A reduction of $237,503 in market value to adjacent properties; and
- A reduction of $2,740 in local and state property tax revenue due to the decreased market value.

Q. Please describe Exhibit A-19 (AT-8) (Hodenpyl).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Hodenpyl Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed

dozens of interviews with local public officials, recreational asset manager,s and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Hodenpyl Dam include:

- A reduction of $6.8 million in gross regional product and 167 jobs; and
- A reduction of $1.9 million in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

Q. Please describe Exhibit A-20 (AT-9) (Loud).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Loud Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Loud Dam include:

- A reduction of $146,927 in gross regional product and 4 jobs; and
- A reduction of $46,341 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

Q. Please describe Exhibit A-21 (AT-10) (Mio).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Mio Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local

stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Mio Dam include:

- A reduction of $1.5 million in gross regional product and 39 jobs; and
- A reduction of $897,308 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

The partial or full removal of the dam would also impact adjacent property values, contributing:

- A reduction of $689,408 in market value to adjacent properties; and
- A reduction of $9,906 in local and state property tax revenue due to the decreased market value.

Q. Please describe Exhibit A-22 (AT-11) (Rogers)

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Rogers Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Rogers Dam include:

- A reduction of $363,395 in gross regional product and 11 jobs; and
- A reduction of $110,316 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

The partial removal of the dam would also impact adjacent property values, including:

- A reduction of $6,709,742 in market value to adjacent properties; and
- A reduction of $95,763 in local and state property tax revenue due to the decreased market value.

The full removal of the dam would also impact adjacent property values, including:

- A reduction of $12,768,166 in market value to adjacent properties; and
- A reduction of $104,426 in local and state property tax revenue due to the decreased market value.

Q. Please describe Exhibit A-23 (AT-12) (Tippy).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Tippy Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Tippy Dam include:

- A reduction of $3 million in gross regional product and 64 jobs; and
- A reduction of $862,909 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

Q. Please describe Exhibit A-24 (AT-13) (Webber).

A. This exhibit contains a comprehensive report, conducted by a third party, to analyze the impacts of partial or full removal of the Webber Dam on the economies surrounding the river hydroelectric facility. The economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. The consultant completed dozens of interviews with local public officials, recreational asset managers, and local stakeholders as part of the data collection process. The potential economic impacts of the partial or full removal of the Webber Dam include:

- A reduction of $281,817 in gross regional product and 7 jobs; and
- A reduction of $83,332 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending.

The partial or full removal of the dam would also impact adjacent property values, contributing:

- A reduction of $1.1 million in market value to adjacent properties; and
- A reduction of $9,943 in local and state property tax revenue due to the decreased market value.

Q. Please explain Exhibit A-25 (AT-14) (Prosperity Group Final Report).

A. The 2024 prosperity group final report consists of feedback from the seven community stakeholder groups tasked with generating their ideas of community prosperity under three different scenarios for the river hydros—whether the river hydro is relicensed, sold, or decommissioned—and in so doing, provide counsel to the Company. Guided by facilitators, prosperity group members provided their perspectives and honed their recommendations for the different scenarios in multiple meetings convened between April and November 2024. The framing questions used to shape the prosperity groups' feedback for each of the three possible scenarios is listed below.

1. Relicensing—How would the prosperity group like Consumers Energy to build a community benefits package in the next relicensing period?
2. What would the prosperity group like Consumers Energy to ask for on behalf of the community should a sale occur?
3. Decommissioning – What are the key investments the prosperity group would like Consumers Energy to make to support the long-term prosperity of the community post-impoundment?

Through various group and individual exercises, facilitated discussions, and presentations on topics such as rural economic development, dam removal and river restoration, and fisheries and wildlife, group members identified priorities for each scenario along with key

actions and launch steps. These priorities were shared with Consumers Energy and taken under advisement as the Company considered its long-term strategy for the river hydro fleet.

In summary, Consumers Energy supported the creation of seven prosperity groups for each river hydro community composed of diverse stakeholders and led by community-based conveners. The Company recognizes the economic contribution the dams and reservoirs have created for communities, and wants to be a partner in supporting community prosperity and demonstrating its long-term commitment to communities. Consumers Energy seeks to build lasting relationships for local prosperity during and after it makes this decision. Consumers Enegy heard from hundreds of people at community meetings in person, plus it has continued to receive input from stakeholders to this day. The Company respects that there are a wide range of opinions about what Consumers Energy might do, and that highlights the role that dams and reservoirs play in shaping the culture and the economy of many Michigan communities. A majority of people have encouraged the Company to find a solution that preserves the reservoirs.

CHARITABLE CONTRIBUTIONS

Q. Please describe Consumers Energy's charitable giving program.

A. Consumers Energy has a long-standing history of supporting Michigan communities, including through the Consumers Energy Foundation, which has been active since 1990.

Q. Will Consumers Energy continue charitable contributions and community support if the sale is approved?

A. The Company's commitment to charitable giving and community support is independent of any specific transaction or energy project. Consumers Energy's charitable efforts have been and will continue to be focused on supporting local needs. These contributions align

with the Company's three focus areas: People, Planet, and Prosperity, and are delivered through grants, sponsorships, and employee volunteerism. Consumers Energy's employee volunteer programs and matching grants to causes and communities that employees care about will remain in place. CMS Energy and Consumers Energy Foundation Programs for Employees and Retirees do not change with the sale of the hydros. These programs include matching gifts, volunteer investment grants, and caring for community grants that can be applied to eligible nonprofit organizations based in Michigan and in the U.S.

Q. Does this conclude your direct testimony?

A. Yes, it does.

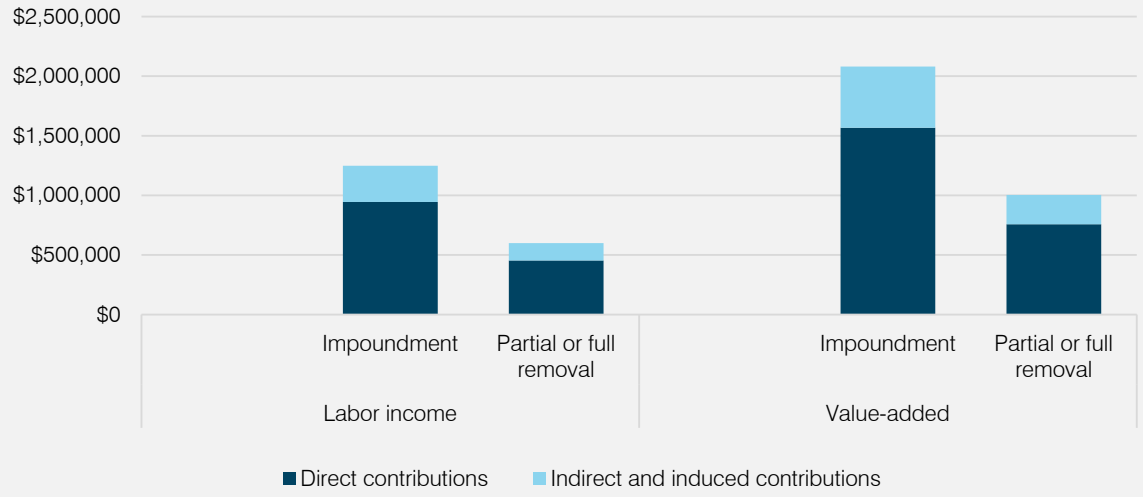
Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Alcona Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 41 fewer jobs in the region and a $1 million reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

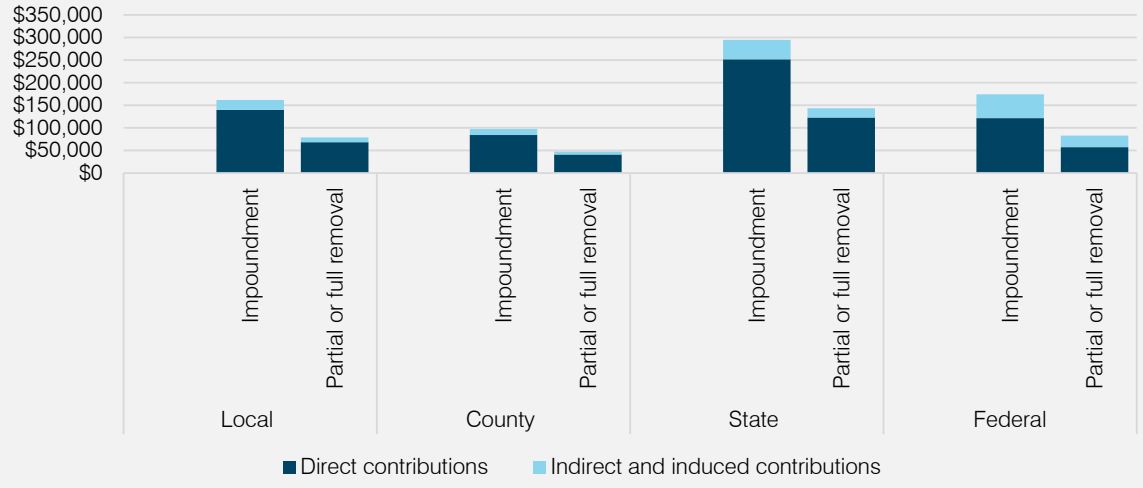

EXHIBIT 2. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $376,041 fewer contributions in total annual tax revenue, with $284,336 of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts— Impoundment and Partial or Full Removal

Source: PSC analysis

Property Value Analysis

PSC compiled assessed and taxable values from the Alcona County Equalization Department for the tax (calendar) year 2022. In other studies of Consumers dams, PSC conducted a property analysis to estimate the impact of partial and/or full dam removal on properties adjacent to the pond. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

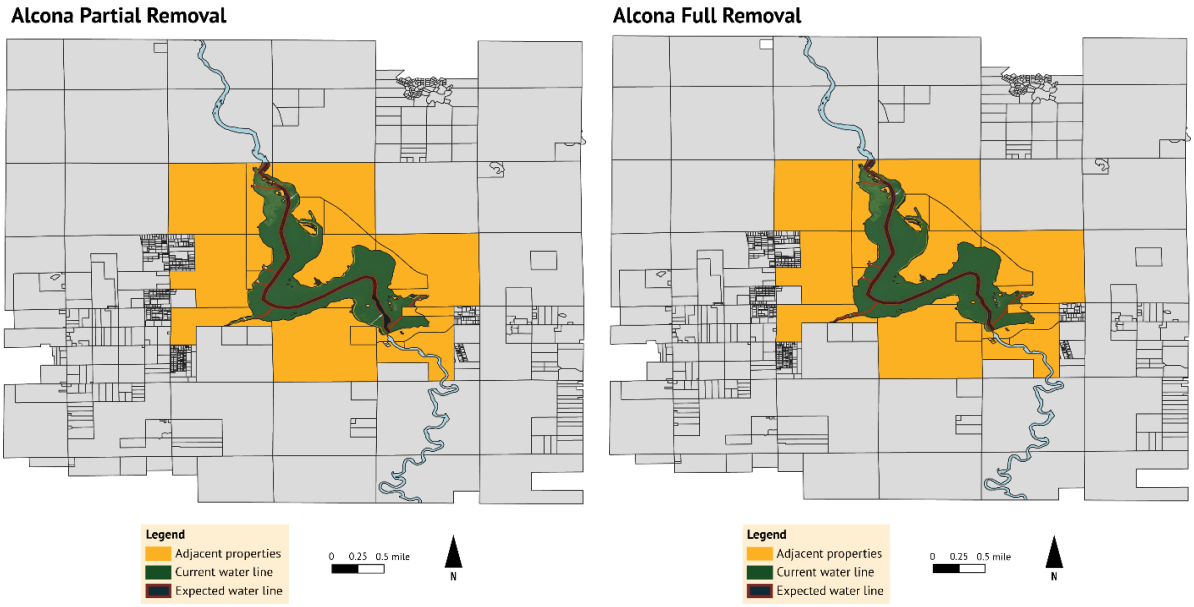
PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Alcona Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background



Alcona Dam is one of six Consumers Energy hydroelectric dams on the Au Sable River in the northwestern Lower Peninsula. Surrounded by the Huron National Forest, it is about three miles west of Glennie, Alcona County, in Curtis Township. Home to approximately 1,200 individuals, Curtis Township represents about one-tenth of the county's total population. Alcona Dam is the longest of Consumers Energy's 13 hydroelectric dams at 4,820 feet. It is 60 feet high and creates an impoundment, Alcona Dam Pond, of approximately 1,075 acres.

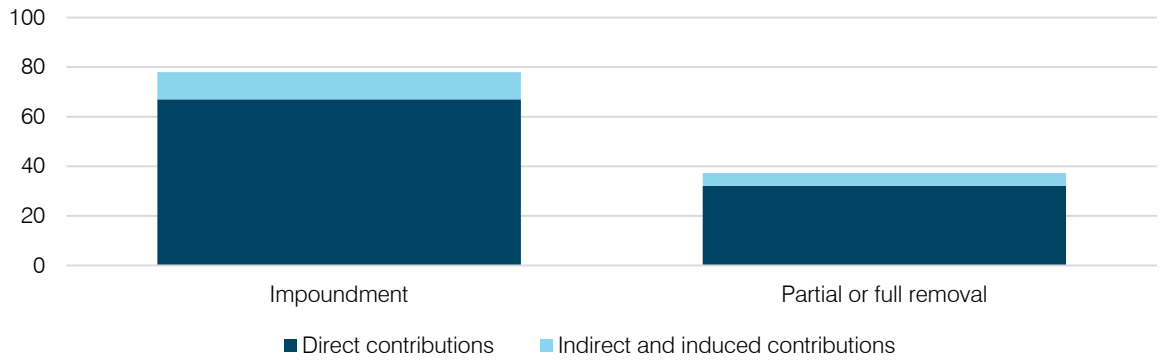
Environmental Context

While no decision has been made on the Alcona Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Where hydrologic conditions persist over time, wetlands will form. This will likely occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal. Exhibit 4 shows the projected shifts in water line and current impoundment-adjacent parcels.

EXHIBIT 4. Partial and Full Removal Parcel Analysis

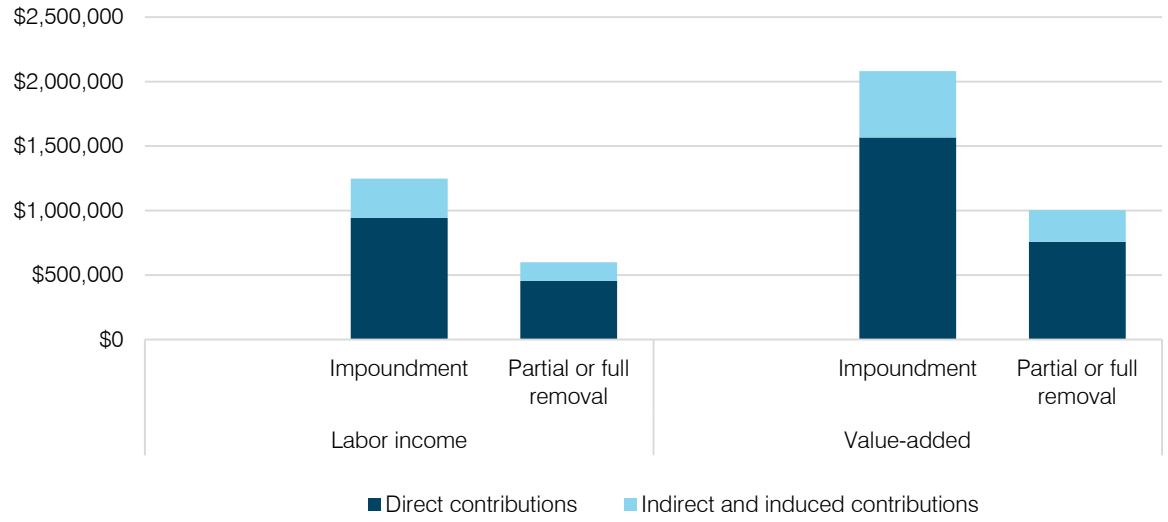
The historic survey maps for the Alcona Dam Pond are limited but indicate that larger areas of uplands are likely to form in the lower impoundment (near the current dam). There is propensity for wetland formation between the river bends in the lower impoundment unless specifically separated with impounded sediment fill. Based on the MNFI wetland viewer, the upper impoundment would also likely have significant wetland formation where prolific wetland complexes have been identified. Given the impoundment's size, upland areas would be expected to form in the wider impoundment areas with selective wetland formation near tributaries, inside channel bends, and lower elevations within the restored topography.



Economic Impact Analysis

To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis



After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC conducted a single analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Alcona Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 41 fewer jobs in the region and a $1 million reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

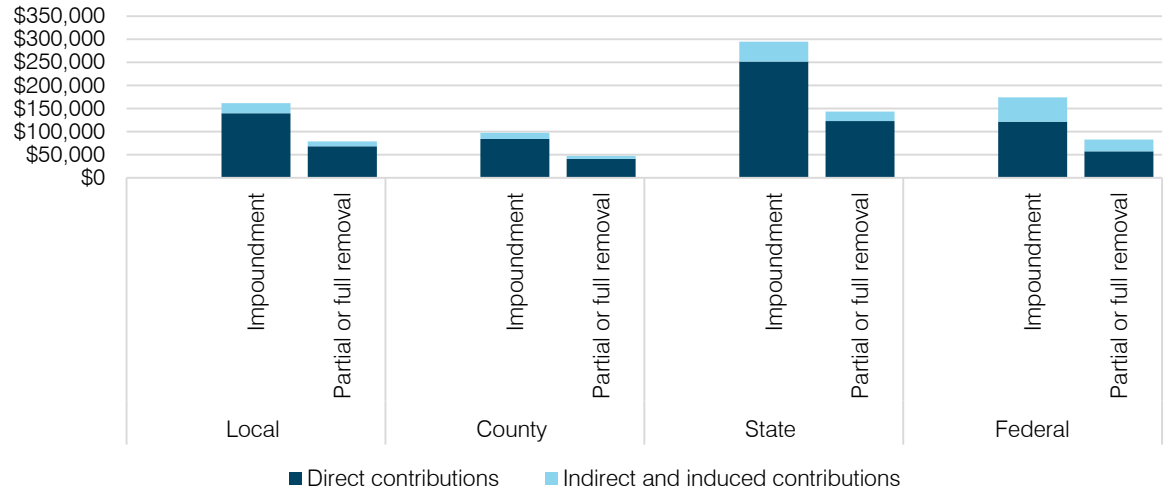


EXHIBIT 6. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $376,041 fewer contributions in total annual tax revenue, with $284,336 of that reduction at the local, county, and state levels (Exhibit 3).

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Alcona Dam Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).

Property Value Analysis

PSC compiled assessed and taxable values from the Alcona County Equalization Department for the tax (calendar) year 2022. In other Consumers dam studies, PSC conducted a property analysis to estimate the impact of partial and full dam removal on impoundment-adjacent properties. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Alcona Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Alcona Dam, which includes:

- A reduction of $1 million in gross regional product and 41 jobs
- A reduction of $376,041 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

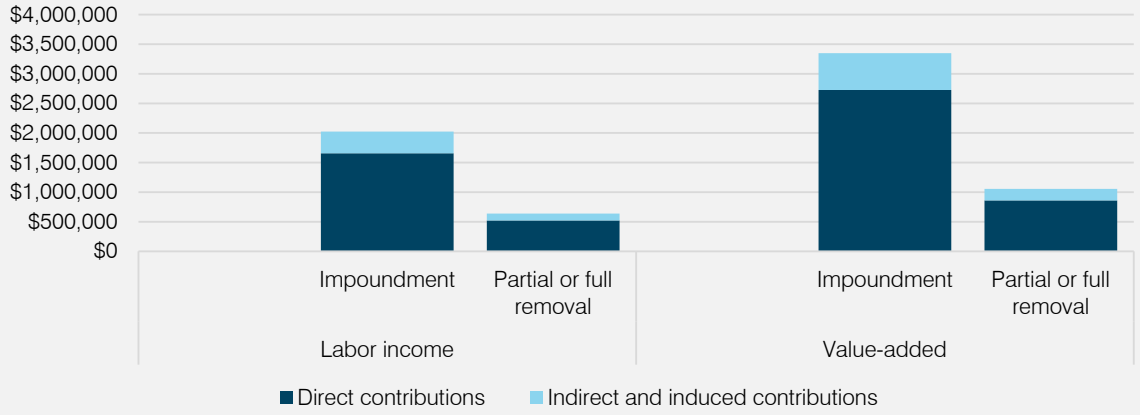
Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's Methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Calkins Bridge Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 41 fewer jobs in the region and a $2.9 million reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

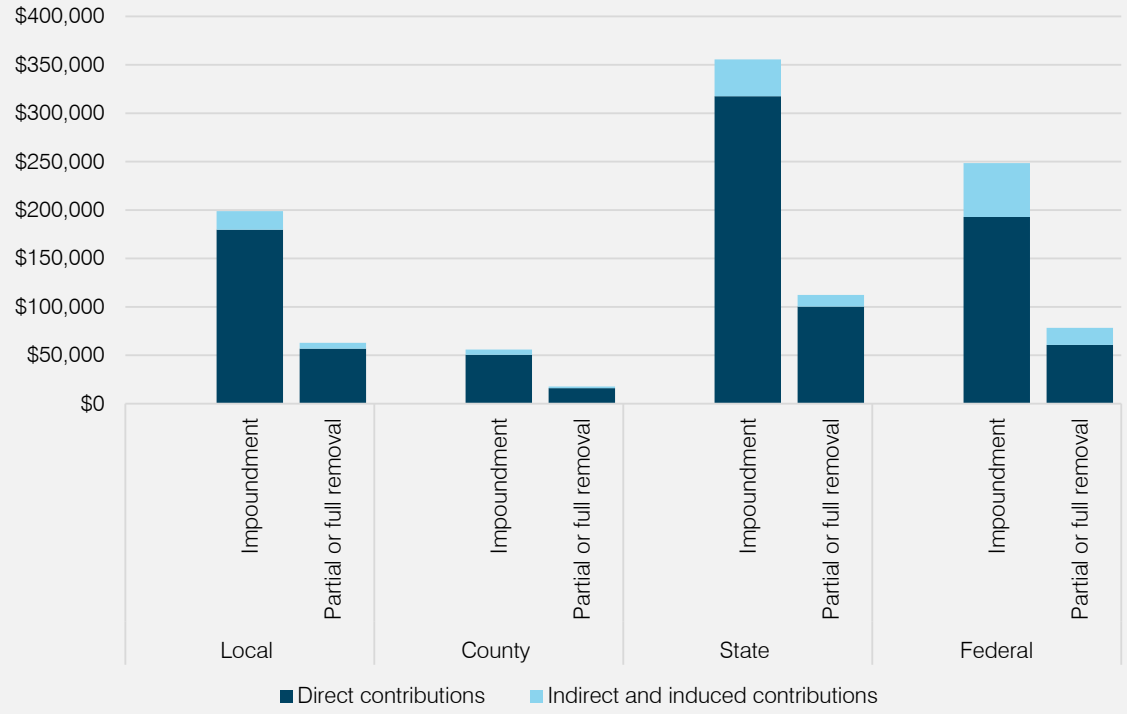


EXHIBIT 2. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $587,668 fewer contributions in total annual tax revenue, with $417,470 of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts— Impoundment and Partial or Full Removal

Source: PSC analysis

Property Value Analysis

To better understand the dam removal impacts on residential property values, PSC analyzed the potential net change in property values and associated annual property tax impact (Exhibit 4).

EXHIBIT 4. Property Analysis Results

	Partial Removal	Full Removal
Number of Properties Analyzed	460	460
Expected Net Property Value Impacts		
Assessed value	-$12,269,842	-$17,785,492
Market value[1]	-$24,539,684	-$35,570,984
Expected Net Property Tax Revenue Impacts[2]		
Taxable value	-$9,397,994	-$13,755,448
Tax revenues	-$389,643	-$570,303
Average millage	41.460	41.460

Sources: Allegan County Equalization Department; PSC analysis

[1] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[2] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's Methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g., partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Property Analysis

Projecting changes in property values is a major component in calculating the economic impact of partially or fully removing the Calkins Bridge Dam. There are two related implications for the local economy. First, changes in the value of one's property affect household wealth. According to the Federal Reserve Board, the value of housing makes up approximately one-half of household wealth on average (Iacoviello 2011; Bostic et al. 2009). Accordingly, unexpected changes in property values can have significant implications for one's financial security. As households spend out of both income and wealth, a change in wealth has economic implications and may result in changes in household expenditures. While the potential for changes in household expenditures exists in what economists call the wealth effects on consumption. Wealth effects on consumption are relatively small as households seek to balance wealth accumulation and lifetime expenditures. Accordingly, this analysis sets out to document the changes in wealth as measured in the expected changes in residential housing values but makes no assumptions on changes in household purchasing behavior because of such wealth effects. Second, public revenues for local government units largely rely on property taxes levied based on the value of the community's underlying properties. Accordingly, a change in property values will have direct implications for government revenues necessary to support public services like the emergency services, local schools, parks, and others. Therefore, in addition to projecting changes in regional wealth, the property analysis will also project expected impacts on public revenues through residential property taxation.

Calkins Bridge Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background

Calkins Bridge Dam, or Allegan Hydroelectric Plant, is the only Consumers Energy hydroelectric dam on the Kalamazoo River. Located in Valley Township, with a population of about 1,800, the Calkins Bridge Dam is near Allegan State Game Area, a 50,000-acre forest. Calkins Bridge Dam was completed in 1935. It is about 30 feet tall and about 1,335 feet in length. The Calkins Bridge Dam impoundment is known as Lake Allegan and is approximately 1,600 acres in area.

Environmental Context

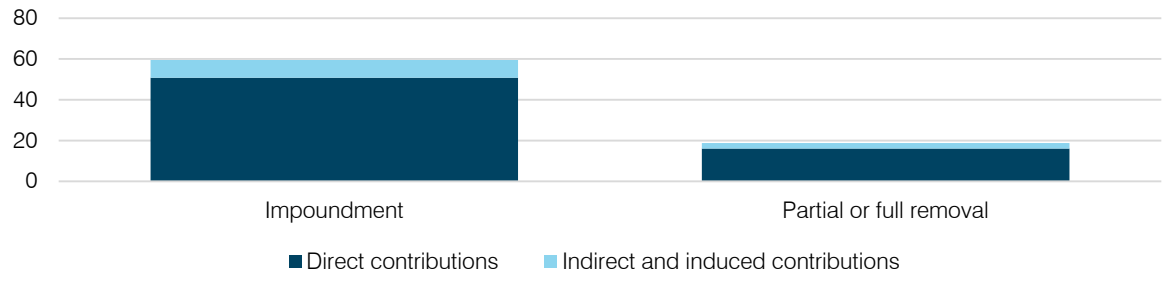
While no decision has been made on the Calkins Bridge Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Where hydrologic conditions persist over time, wetlands will form. This transition likely will occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal.

Partial and full removal scenarios for the Calkins Bridge Dam are likely to produce significantly different environmental conditions for the current impoundment, particularly on its lower end near the dam. A partial removal of the dam is likely to maintain a sizable impoundment within the existing lower impoundment area. The bottomlands exposed in the lower impoundment that are closer to the existing dam would be expected to form as upland areas. Within the middle and upper impoundment, a mix of wetland and upland habitat types is expected to form. Wetlands will likely form along inside bends of the restored channel, along tributaries entering the impoundment, and near where existing adjacent wetland complexes are present and would likely drain toward the restored channel.

A full dam removal is likely to produce significantly more upland habitat formation in the lower impoundment area than would a partial removal. Neither the historic survey of the dam nor the MNFI wetland viewer indicate wetland adjacent to Lake Allegan or a history of wetland habitat types within the

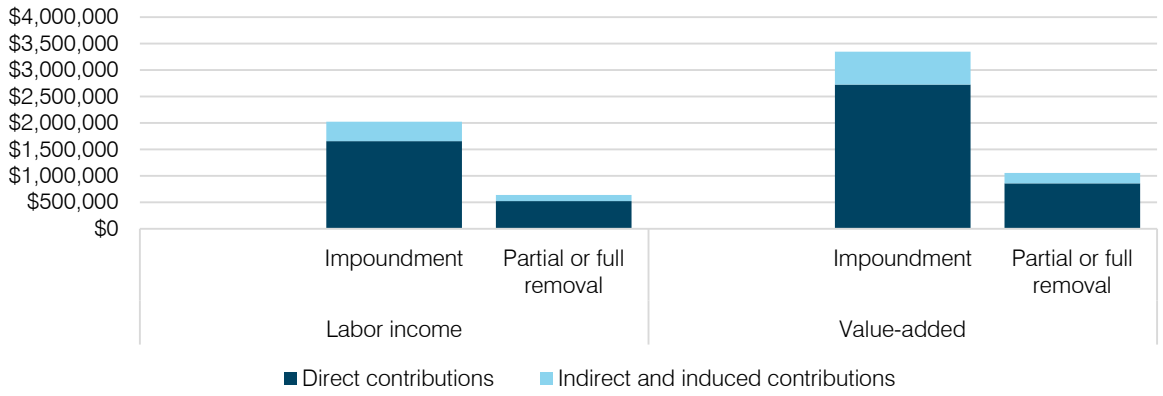
impoundment. Wetland habitat is expected to form along the inside bends of the restored river channel in the lower impoundment and the same mix of wetland and upland habitat types is expected in the middle and upper impoundment as in the partial dam removal scenario.



Economic Impact Analysis

To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding Lake Allegan. To align with the previously released contribution study, PSC also estimated Airbnb rental costs and occupancy in this study because the analysis did not identify any impoundment-adjacent overnight or seasonal camping facilities. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis



After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. As detailed in the Methodology section of this report, PSC analysis does not make assumptions about what actions individuals, businesses, or organizations would take in response to a partial or full dam removal, so the results of a partial dam removal analysis are likely to be similar to those of a full dam removal scenario in the short term. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Calkins Bridge Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 41 fewer jobs in the region and a $2.9 million reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

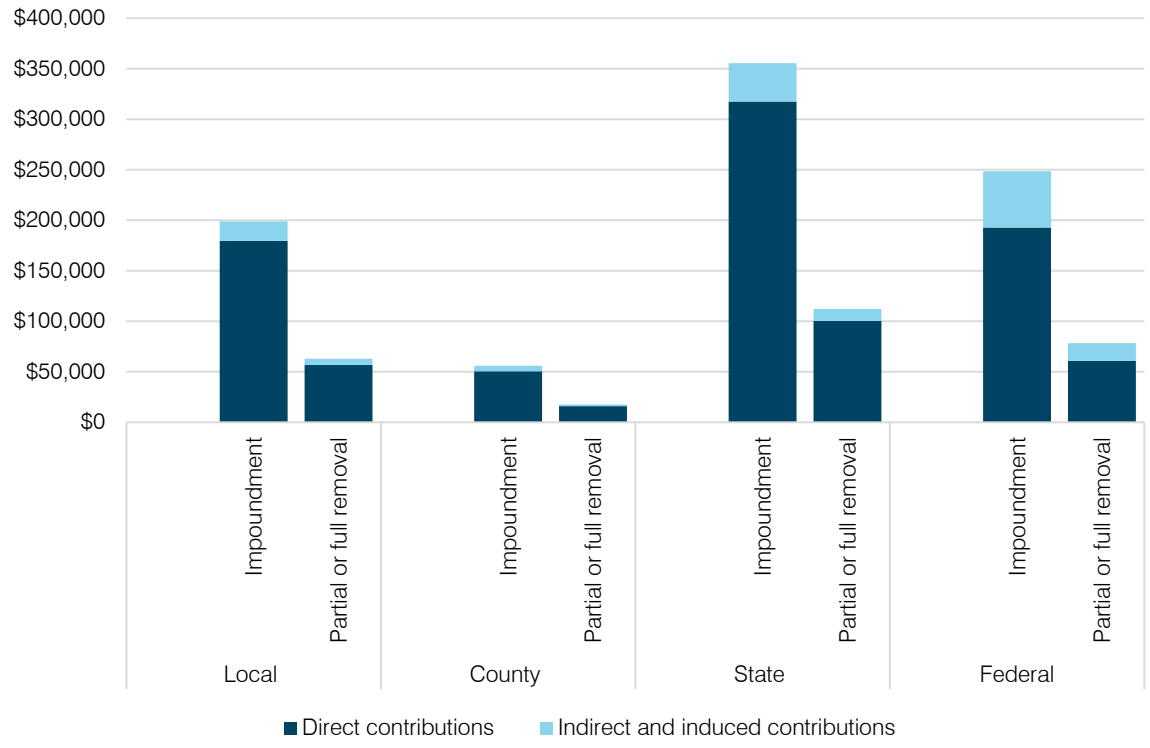


EXHIBIT 6. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $587,668 fewer contributions in total annual tax revenue, with $417,470 of that reduction at the local, county, and state levels (Exhibit 3).

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Lake Allegan, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

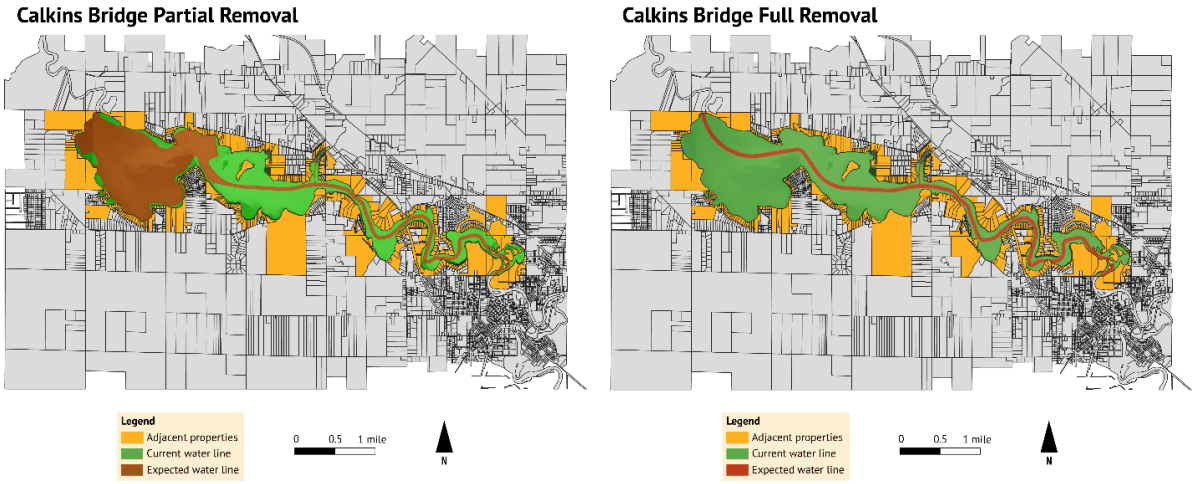
Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).



Property Value Analysis

Lake Allegan has 460 adjacent residential lots that likely benefit from access to the current impoundment. To what extent residential property values would be affected by a partial or full dam removal depends on a property's proximity to the resulting water's edge. This is because relative to a full dam removal, a partial removal retains a small impoundment that extends the water's edge to more properties. Exhibit 8 shows two maps of property plats around Lake Allegan, one depicting the extent of the expected water line under a partial dam removal and one showing the same under a full dam removal. The expected extant of the water body after dam modification is shown by the green and blue insert. All other points along the river system are assumed to be invariant between the two scenarios and from the current relationship with the water system.

PSC determined the potential net change in property values and associated annual property tax impact of the proposed dam modifications. These are highlighted in Exhibit 9. Accordingly, the relatively smaller impoundment expected with a partial dam removal will provide waterfront access to more properties than under a full removal. Because more lots will have greater water proximity than with full removal, the partial-removal scenario would be expected to have a lesser overall negative effect on overall residential property values and annual residential property tax revenues. Because there are residential properties differentially impacted by the partial and full dam removal scenarios, this assessment anticipates that the partial and full dam removal scenarios will have measurable differences in effects. As Exhibit 9 indicates,

460 impoundment-adjacent properties will experience a cumulative reduction in market values of around $24,539,684 under a partial dam removal and $35,570,984 under a full removal. Similarly, annual residential property tax revenues are expected to decrease by about $389,643 or $570,303 under the partial and full removal scenarios, respectively.

EXHIBIT 8. Partial and Full Removal Parcel Analysis

The results of PSC analysis on the potential net change in property values and associated annual property tax impact are highlighted in Exhibit 9.

EXHIBIT 9. Property Analysis Results

	Partial Removal	Full Removal
Number of Properties Analyzed	460	460
Expected Net Property Value Impacts		
Assessed value	-$12,269,842	-$17,785,492
Market value[3]	-$24,539,684	-$35,570,984
Expected Net Property Tax Revenue Impacts[4]		
Taxable value	-$9,397,994	-$13,755,448
Tax revenues	-$389,643	-$570,303
Average millage	41.460	41.460

Sources: Allegan County Equalization Department; PSC analysis

[3] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[4] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Calkins Bridge Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Calkins Bridge Dam, which includes:

- A reduction of $2.9 million in gross regional product and 41 jobs
- A reduction of $587,668 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

The partial removal of the dam will also impact adjacent property values, including:

- A reduction of $24.5 million in market value to adjacent properties
- A reduction in $389,643 in local and state property tax revenue due to the decreased market value

The full removal of the dam will also impact adjacent property values, including:

- A reduction of $35.6 million in market value to adjacent properties
- A reduction in $507,303 in local and state property tax revenue due to the decreased market value

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment adjacent will change after becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

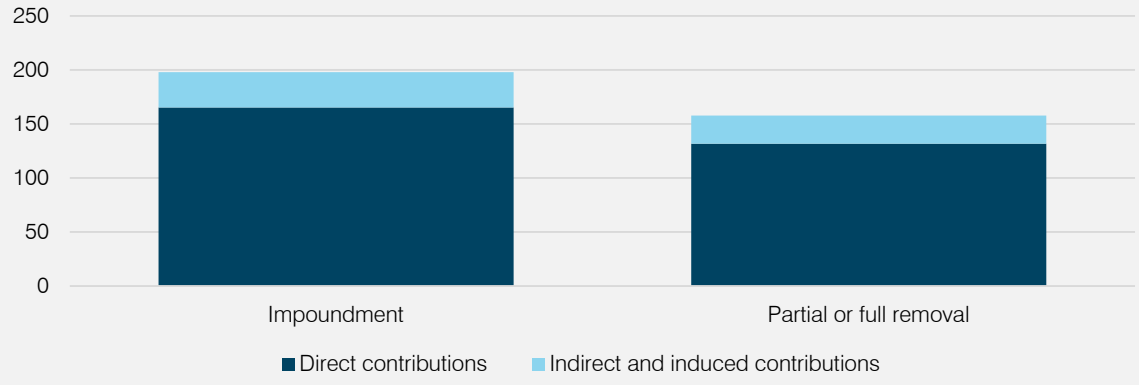
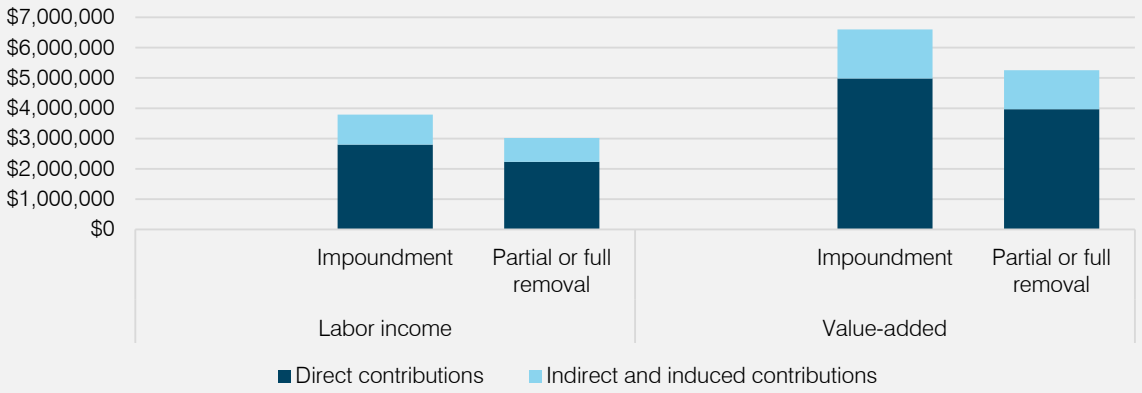
APPENDIX A: METHODOLOGY 21



Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Cooke Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 40 fewer jobs in the region and a $1.3 million reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

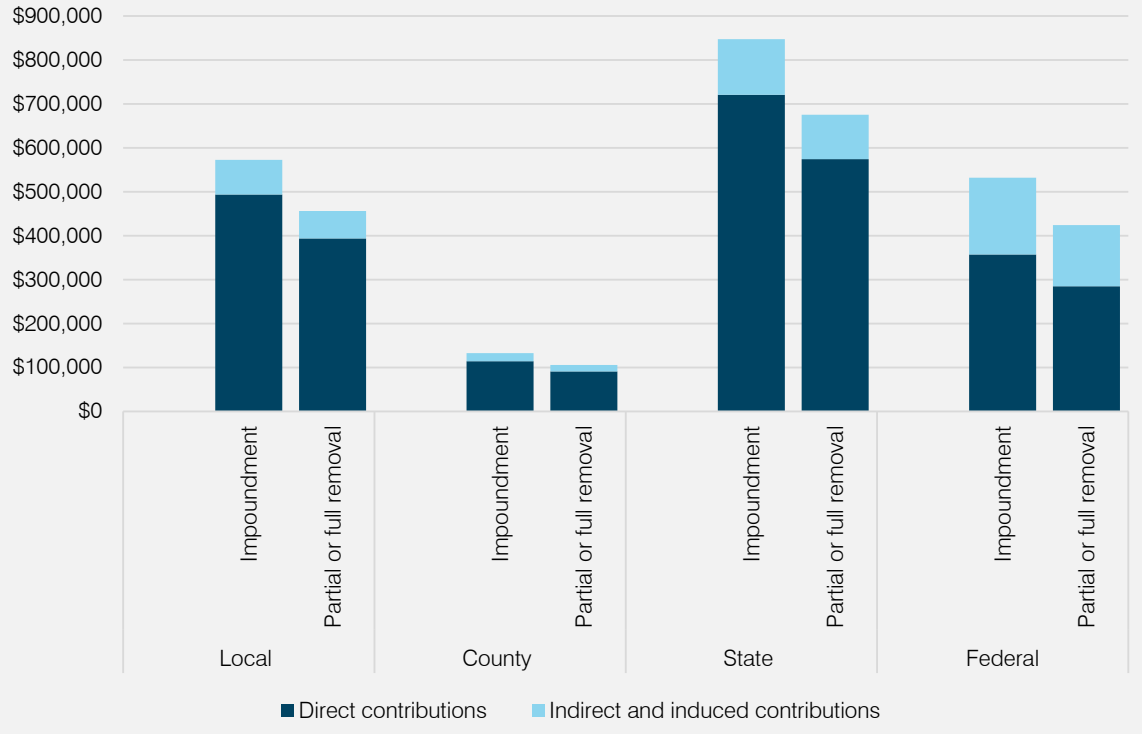


EXHIBIT 2. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

These estimated shifts in recreational activity will also result in $423,383 fewer contributions in total annual tax revenue, with $315,283 of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts— Impoundment and Partial or Full Removal

Property Value Analysis

PSC compiled assessed and taxable values from the Iosco County Equalization Department for the tax (calendar) year 2022. In other Consumers dam studies, PSC conducted a property analysis to estimate the impact of partial and full dam removal on properties adjacent to the pond. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

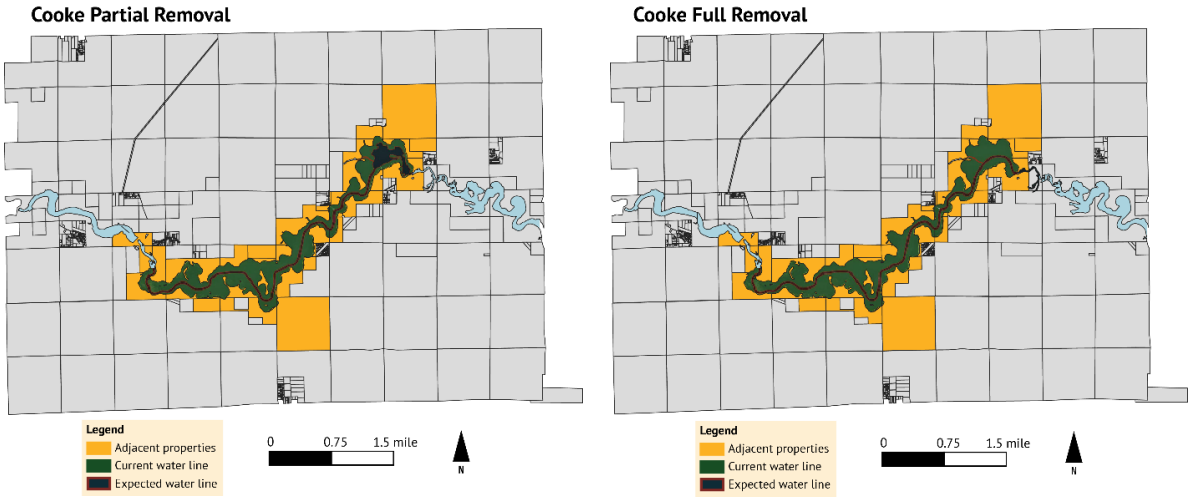
PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Cooke Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background



Completed in 1911, Cooke Dam was the first of the six Au Sable River dams to be constructed. Like most of the others, Cooke Dam is located in Oscoda Township, Iosco County, and is surrounded by Huron National Forest. It is situated east of Five Channels Dam and west of Foote Dam. It is about 50 feet tall and 900 feet in length. Cooke Dam Pond is approximately 1,700 acres in area, making it the fourth largest impoundment created by one of the 13 Consumers hydroelectric dams in Michigan.

Environmental Context

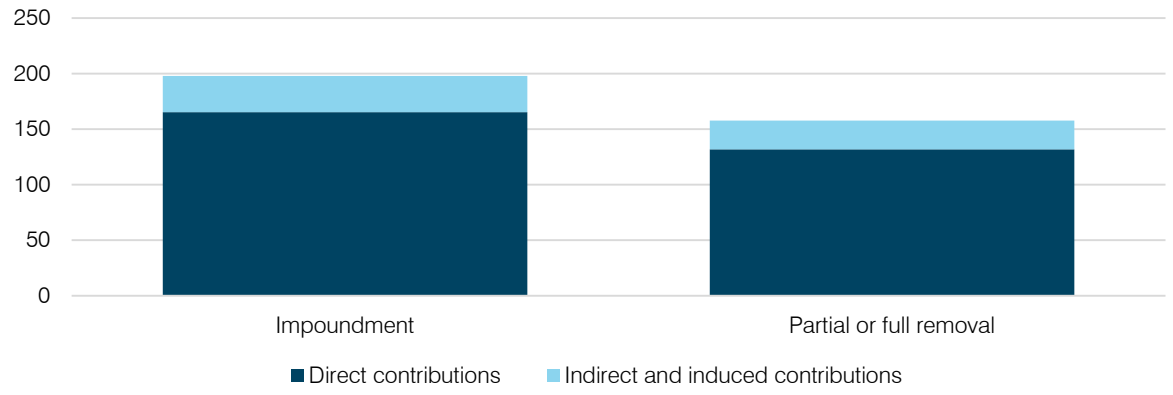
While no decision has been made on the Cooke Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Where hydrologic conditions persist over time, wetlands will form. This will likely occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal. Exhibit 4 shows the projected shifts in water line and current impoundment-adjacent parcels.

EXHIBIT 4. Partial and Full Removal Parcel Analysis

There would likely be few differences in environmental shifts between a partial or full removal of Cooke Dam. The MNFI wetland map viewer indicates a few areas where wetland habitat would be expected to form due to adjacent wetlands, including areas on the western and eastern ends of the impoundment. Wetlands would also be expected to form along the water's edge of the restored river channel, within inside bends, and where tributaries enter the former impoundment. The remainder of the impounded area would potentially form upland habitat.

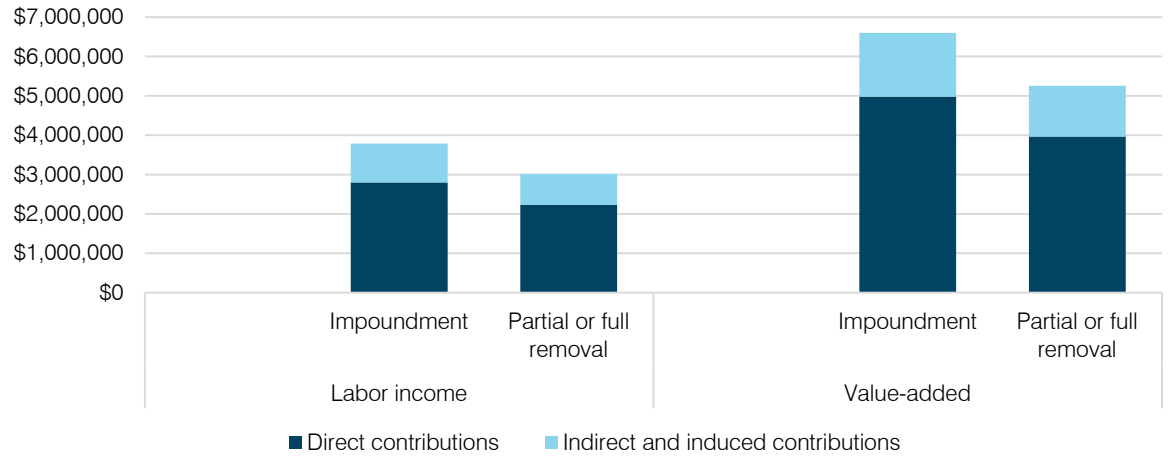
Economic Impact Analysis



To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis

After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC conducted a single analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Cooke Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts



during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 40 fewer jobs in the region and a $1.3 million reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

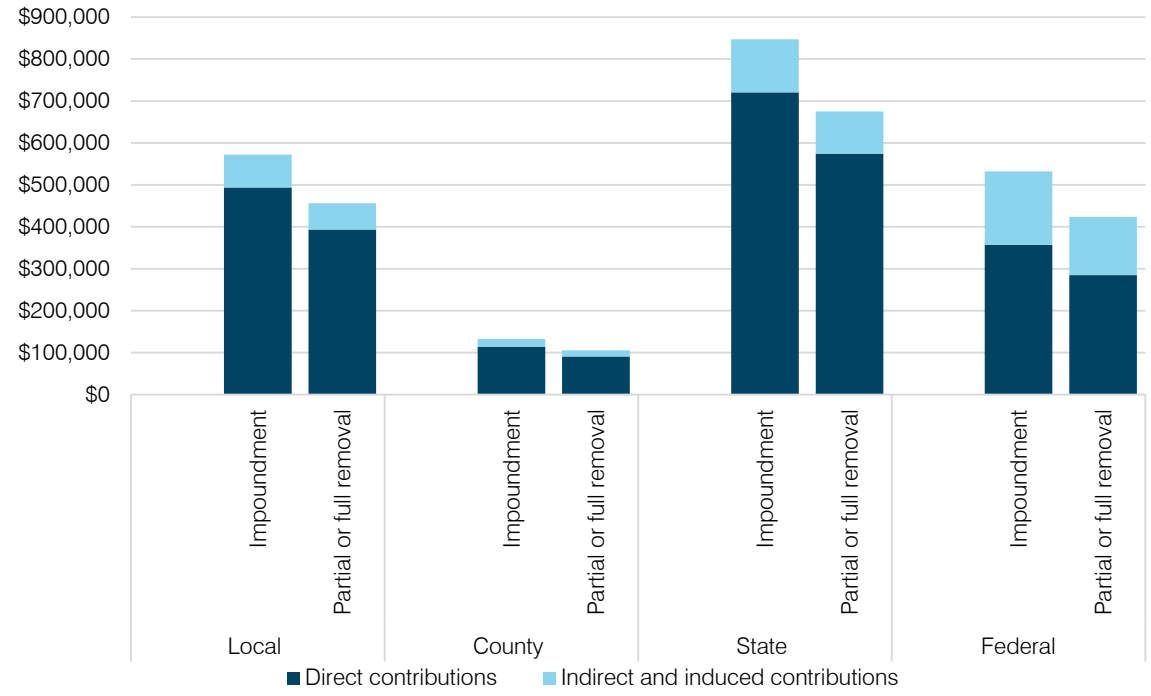


EXHIBIT 6. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will result in $423,383 fewer contributions in total annual tax revenue, with $315,283 of that reduction at the local, county, and state levels (Exhibit 7).

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Cooke Dam Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Cooke Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Cooke Dam, which includes:

- A reduction of $1.3 million in gross regional product and 40 jobs
- A reduction of $423,383 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

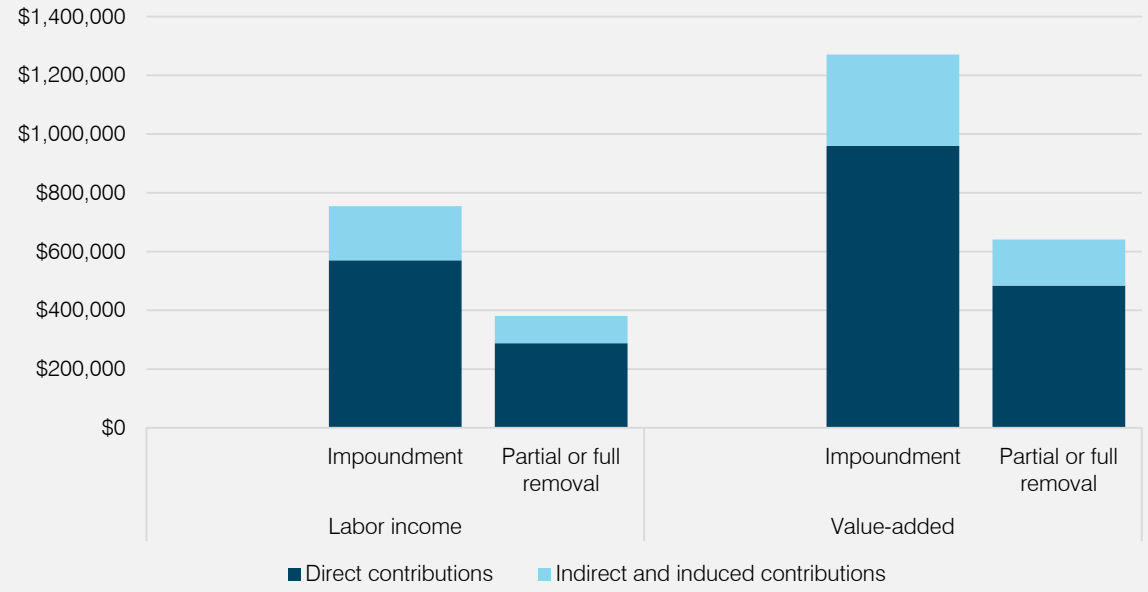
Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. After reviewing maps of the area, PSC conducted a single recreational analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Croton Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 15 fewer jobs in the region and a $629,499 reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

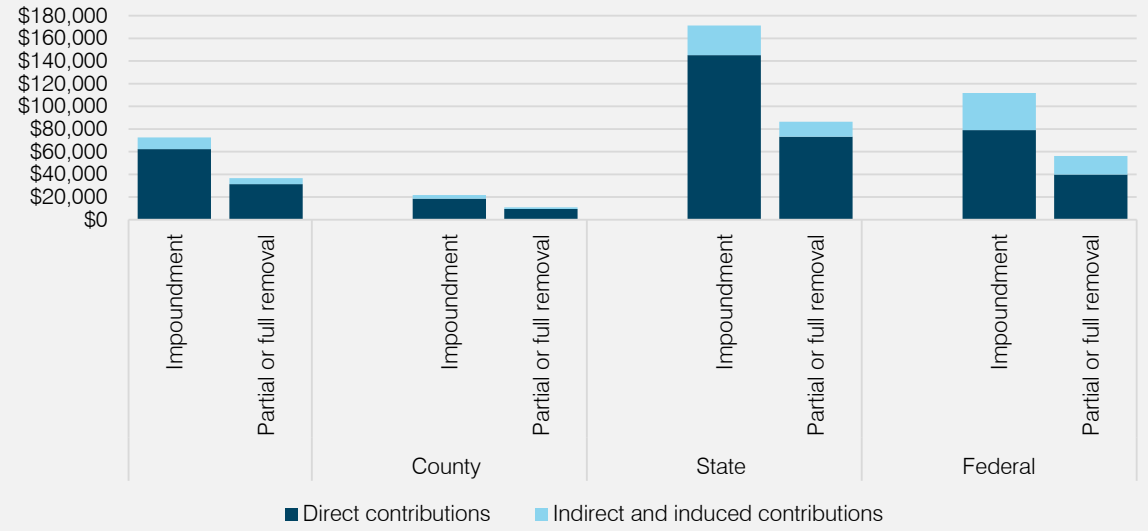


EXHIBIT 2. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will result in $187,095 fewer contributions in total annual tax revenue, with $131,573 of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

Property Value Analysis

To better understand the dam removal impacts on residential property values, PSC analyzed the potential net change in property values and associated annual property tax impact (Exhibit 4).

EXHIBIT 4. Property Analysis Results

	Partial Full Removal
Number of Properties Analyzed	612
Expected Net Property Value Impacts	
Assessed value	-$12,670,480
Market value[1]	-$25,340,960
Expected Net Property Tax Revenue Impacts[2]	
Taxable value	-$10,256,156
Tax revenues	-$372,837
Average millage	36.352

Sources: Newaygo County Equalization Department, PSC analysis

[1] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[2] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Property Analysis

Projecting changes in property values is a major component in calculating the economic impact of partially or fully removing the Croton Dam. There are two related implications for the local economy. First, changes in the value of one's property affect household wealth. According to the Federal Reserve Board, the value of housing makes up approximately one-half of household wealth on average (Iacoviello 2011; Bostic et al. 2009). Accordingly, unexpected changes in property values can have significant implications for one's financial security. As households spend out of both income and wealth, a change in wealth has economic implications and may result in changes in household expenditures. While the potential for changes in household expenditures exists in what economists call the wealth effects on consumption. Wealth effects on consumption are relatively small as households seek to balance wealth accumulation and lifetime expenditures. Accordingly, this analysis sets out to document the changes in wealth as measured in the expected changes in residential housing values but makes no assumptions on changes in household purchasing behavior because of such wealth effects. Second, public revenues for local government units largely rely on property taxes levied based on the value of the community's underlying properties. Accordingly, a change in property values will have direct implications for government revenues necessary to support public services like the emergency services, local schools, parks, and others. Therefore, in addition to projecting changes in regional wealth, the property analysis will also project expected impacts on public revenues through residential property taxation.

Croton Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background

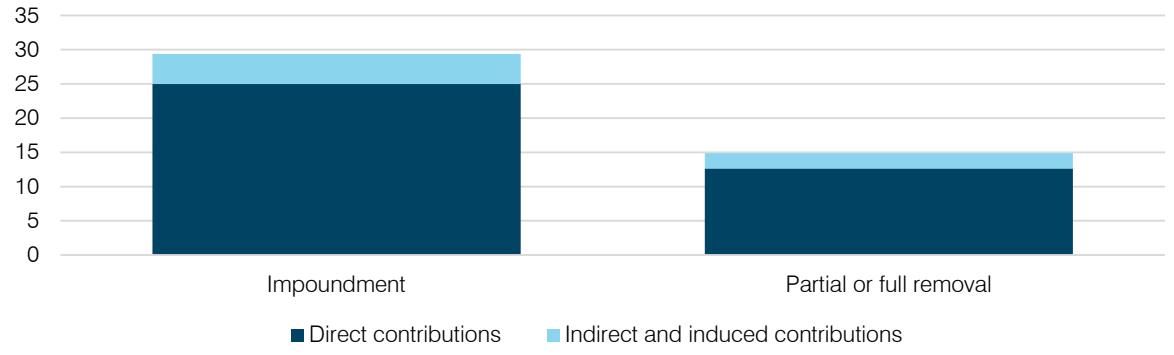
Croton Dam is the southernmost of the three Consumers Energy hydroelectric dams on the Muskegon River. It is about six miles southeast of Hardy Dam, in Croton Township, Newaygo County. The township has a population of approximately 3,200 individuals. Like Rogers and Hardy Dams, Croton Dam is an earthen embankment dam. It was completed in 1907, and two additional generating units were constructed in 1915. At 700 feet long, Croton Dam is the smallest in length of Consumers' 13 hydroelectric dams. It is about 45.5 feet high, and the resulting impoundment, Croton Dam Pond, is approximately 1,209 acres in area.

Environmental Context

While no decision has been made on the Croton Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Over time, wetlands will begin to take hold, forming where the hydrologic conditions persist for their creation. This transition likely will occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal.

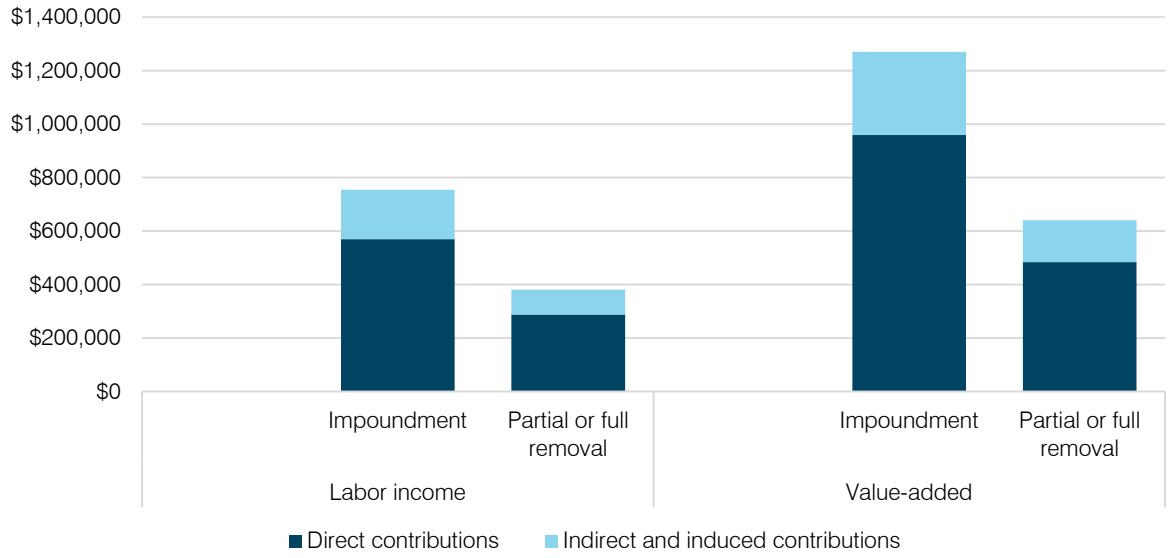
The historic survey maps of the Croton Dam impoundment do not indicate swamps or marsh land. The land was identified as "cultivated" and "timbers," which we interpreted as uplands. After reviewing the historical assessment, we would expect the majority of the former bottomlands to form as upland areas. A partial dam removal scenario would likely have similar delineations, with the exception of the immediate floodplain areas bounding the restored channel or small impoundment. Per the MNFI wetland map viewer, there are wetlands present on the fringes of the eastern lobe of the current impoundment. This area of the historic survey also noted "flowage" as the primary land description, which indicates that this area may experience some wetland formation.



Economic Impact Analysis

To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis



After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC conducted a single recreational analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Croton Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 15 fewer jobs in the region and a $629,499 reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

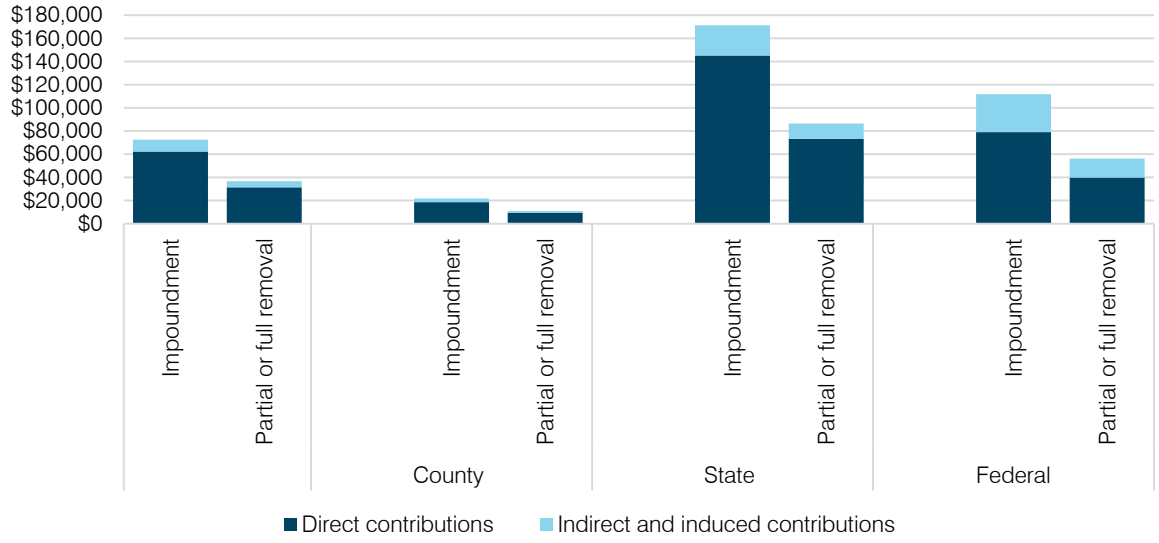


EXHIBIT 6. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will result in $187,095 fewer contributions in total annual tax revenue, with $131,573 of that reduction at the local, county, and state levels (Exhibit 7).

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Croton Dam Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

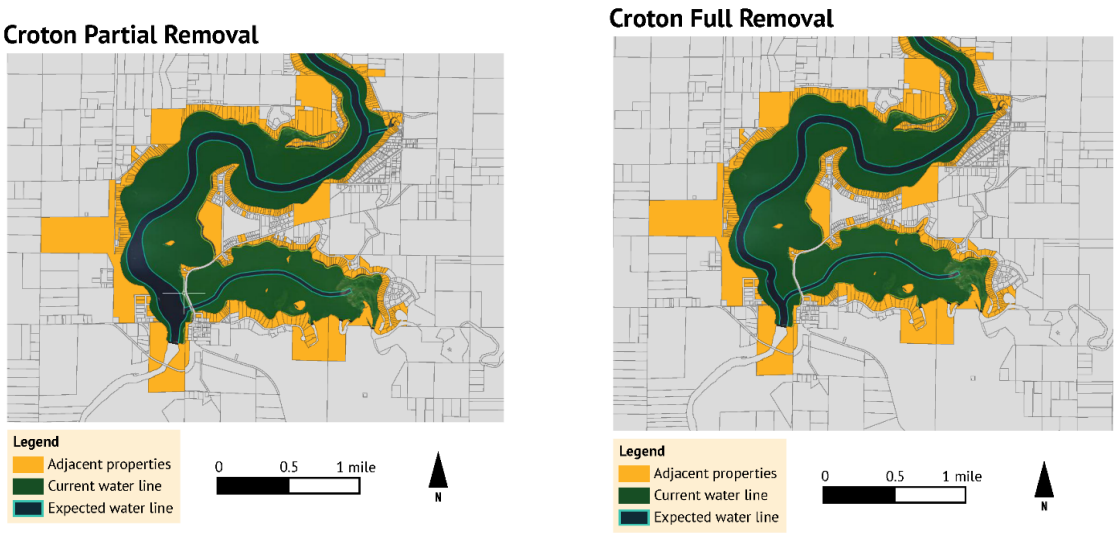
Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).



Property Value Analysis

Residential lots adjacent to the existing impoundment include 612 properties around Croton Pond. To what extent residential property values would be affected by a partial or full dam removal depends on a property's proximity to the resulting water's edge. This is because relative to a full dam removal, a partial removal retains a small impoundment that extends the water's edge to more properties. Exhibit 8 shows two maps of property plats around Croton Pond, one depicting the extent of the expected water line under a partial dam removal and one showing the same under a full dam removal. The expected extant of the water body after dam modification is shown by the green and blue insert. All other points along the river system are assumed to be invariant between the two scenarios and from the current relationship with the water system.

PSC determined the potential net change in property values and associated annual property tax impact, highlighted in Exhibit 9. Accordingly, the relatively small impoundment expected with a partial dam removal will provide waterfront access to more properties than under a full removal. Because more lots will have greater water proximity than with full removal, the partial-removal scenario would be expected to have a lesser overall negative effect on overall residential property values and annual residential property tax revenues. However, because there are few residential properties immediately adjacent to the Croton Dam, this assessment anticipates that the partial and full dam removal scenarios will have comparable effects. As Exhibit 9 indicates, 612 impoundment-adjacent properties will experience a

cumulative reduction in market values of around $25.3 million under each removal scenario. Similarly, annual residential property tax revenues are expected to decrease by about $372,345 or $372,837 under the partial and full removal scenarios, respectively.

EXHIBIT 8. Partial and Full Removal Parcel Analysis

The results of PSC analysis on the potential net change in property values and associated annual property tax impact are highlighted in Exhibit 9.

EXHIBIT 9. Property Analysis Results

	Partial or Full Removal
Number of Properties Analyzed	612
Expected Net Property Value Impacts	
Assessed value	-$12,670,480
Market value[3]	-$25,340,960
Expected Net Property Tax Revenue Impacts[4]	
Taxable value	-$10,256,156
Tax revenues	-$372,837
Average millage	36.352

Sources: Newaygo County Equalization Department, PSC analysis

[3] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[4] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Croton Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Croton Dam, which includes:

- A reduction of $629,499 in gross regional product and 15 jobs
- A reduction of $187,095 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

The partial or full removal of the dam will also impact adjacent property values, including:

- A reduction of $25.3 million in market value to adjacent properties
- A reduction of about $372,837 in local and state property tax revenue due to the decreased market value

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

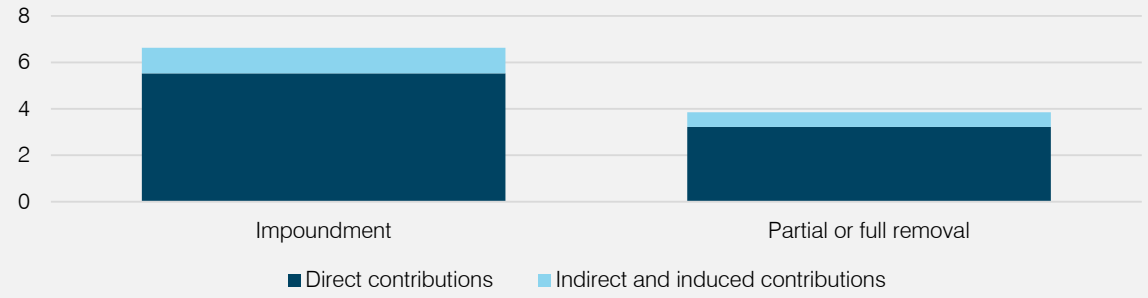
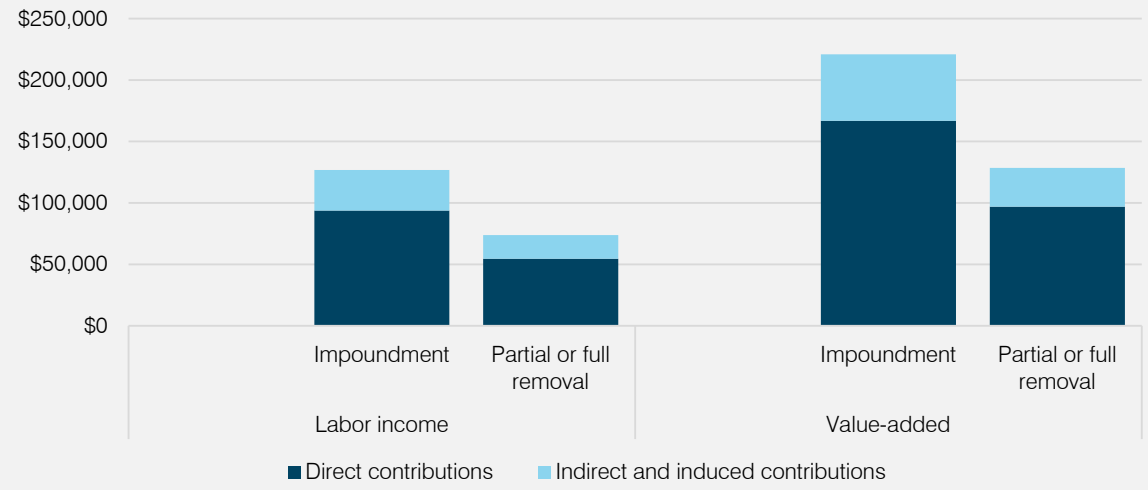
APPENDIX A: METHODOLOGY 21



Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Five Channels Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 3 fewer jobs in the region and a $92,476 reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

These estimated shifts in recreational activity will also result in $29,183 fewer contributions in total annual tax revenue, with $21,732 of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts— Impoundment and Partial or Full Removal

Property Value Analysis

PSC compiled assessed and taxable values from the Iosco County Equalization Department for the tax (calendar) year 2022. In other studies of Consumers dams, PSC conducted a property analysis to estimate the impact of partial and/or full dam removal on properties adjacent to the pond. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

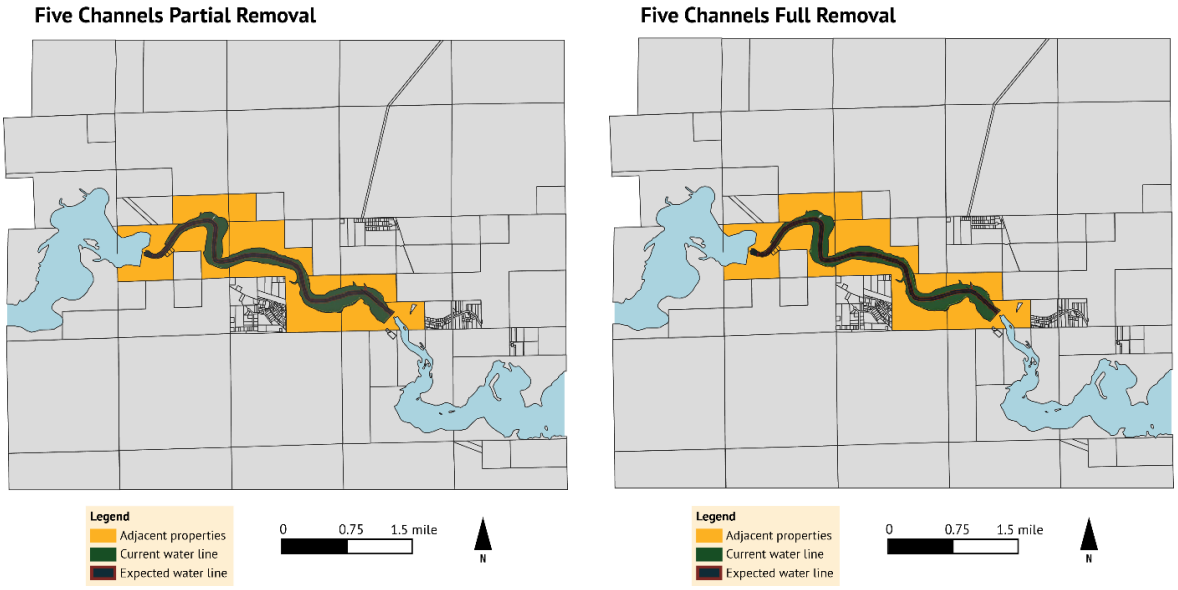
PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Five Channels Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background



The Five Channels Dam is the smallest of the six Consumers hydroelectric dams on the Au Sable River. Located in Oscoda Township, the Five Channels Dam measures about 40 feet in height and about 800 feet in length. Five Channels Pond is also the smallest of the Consumers impoundments and like the other Au Sable dams, Five Channels is surrounded by Huron National Forest.

Environmental Context

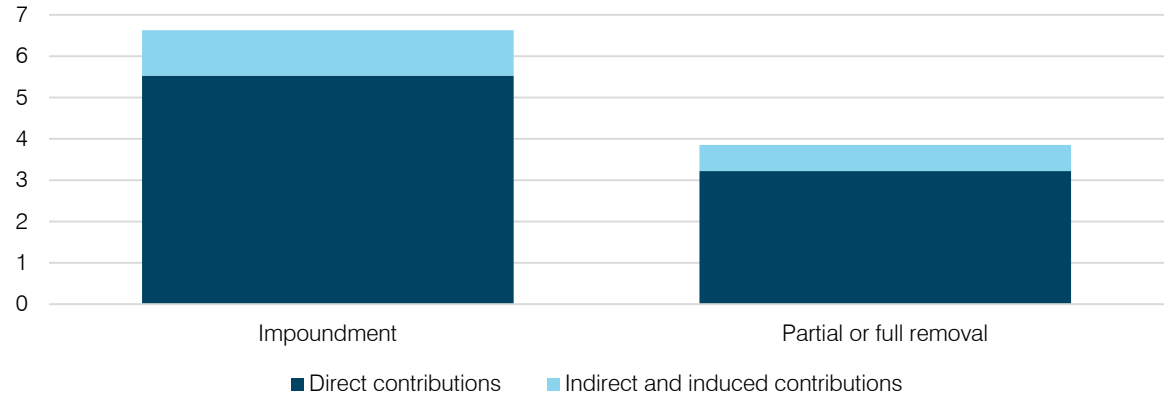
While no decision has been made on the Five Channels Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Where hydrologic conditions persist over time, wetlands will form. This will likely occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal. Exhibit 4 shows the projected shifts in water line and current impoundment-adjacent parcels.

EXHIBIT 4. Partial and Full Removal Parcel Analysis

The historic survey and MNFI wetland map viewer for the Five Channels Dam indicate wetlands along the northern portion of the impoundment. It is likely a large majority of the bottomlands between the river and the northern impoundment water's edge would have a higher probability of forming wetlands. Additionally, there are wetland indicators along the southern edge of the impoundment, near the dam, so it is likely the bottomlands within that portion of the impoundment would have a higher chance of wetland formation as well. It is unclear to what extent wetlands or uplands would form elsewhere, however there is a higher likelihood of wetland formation in areas that are in proximity to other adjacent wetlands.

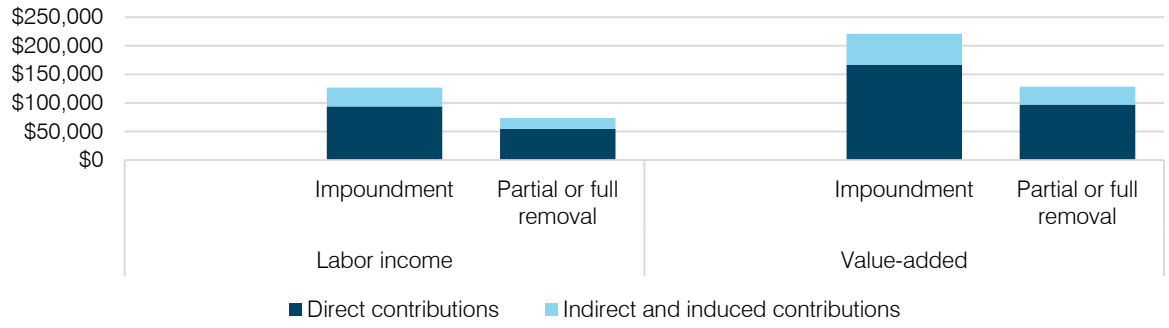
Economic Impact Analysis



To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis

After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC



conducted a single analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Five Channels Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 3 fewer jobs in the region and a $92,476 reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

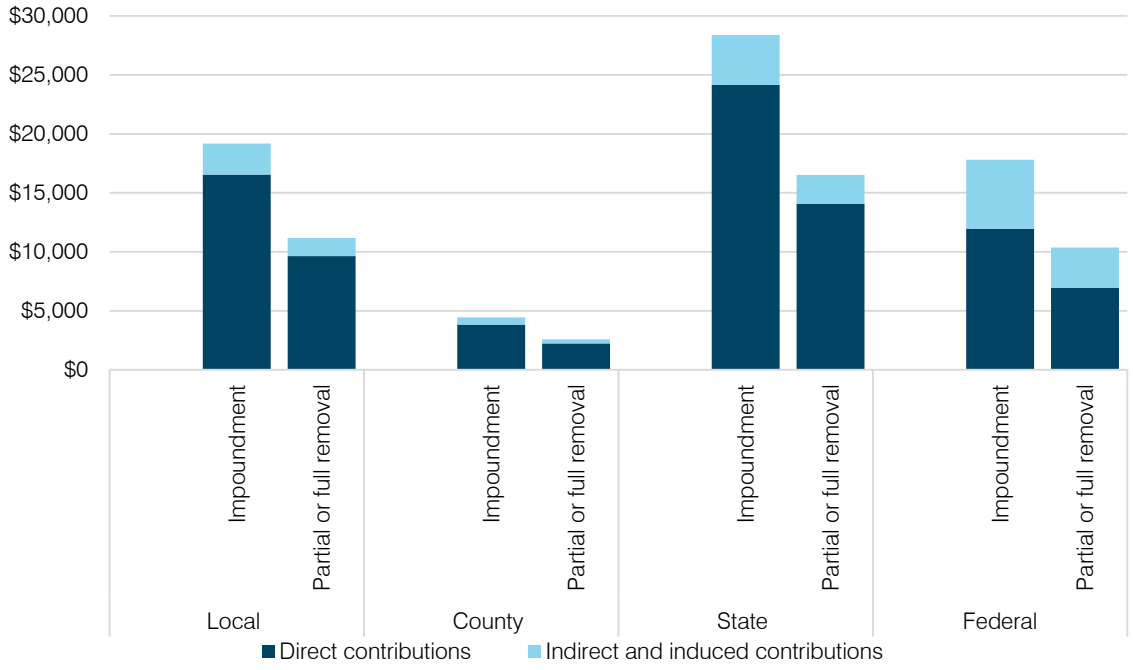


EXHIBIT 6. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will result in $29,183 fewer contributions in total annual tax revenue, with $21,732 of that reduction at the local, county, and state levels (Exhibit 7).

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Five Channels Dam Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).

Property Value Analysis

PSC compiled assessed and taxable values from the Iosco County Equalization Department for the tax (calendar) year 2022. In other Consumers dam studies, PSC conducted a property analysis to estimate the impact of partial and full dam removal on properties adjacent to the pond. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Five Channels Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Five Channels Dam, which includes:

- A reduction of $92,4761 in gross regional product and 3 jobs
- A reduction of $29,183 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

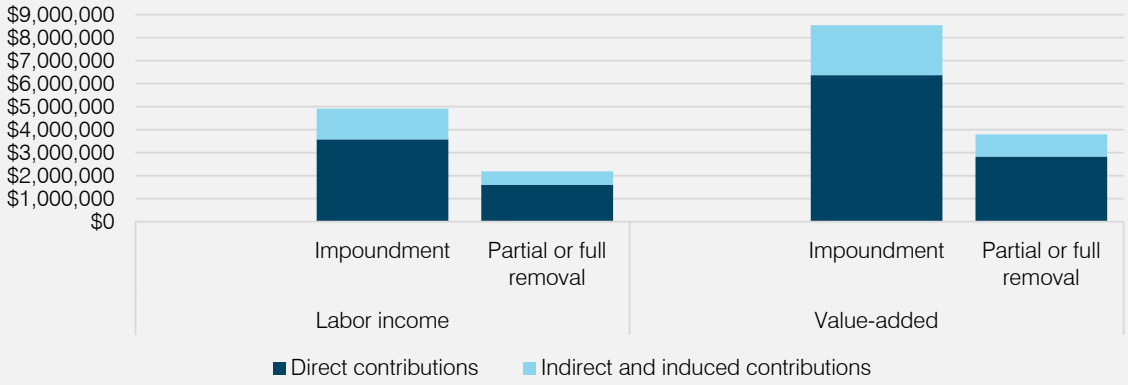
Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Foote Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 151 fewer jobs in the region and a $4.7 million reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

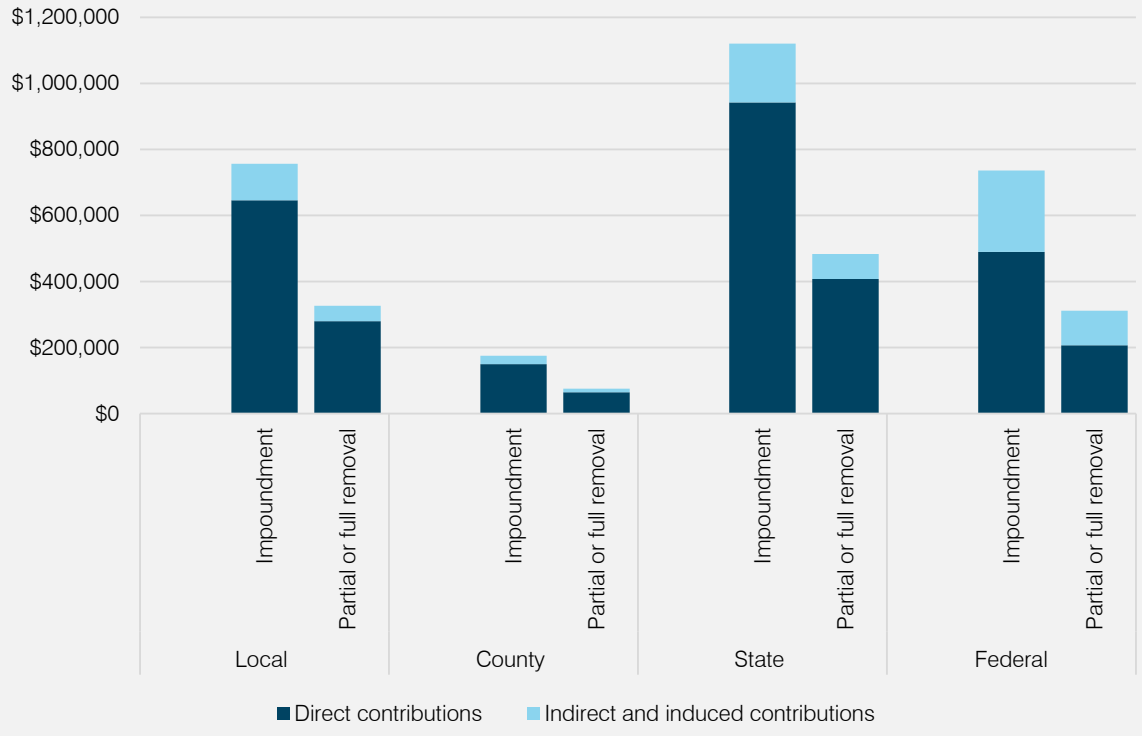


EXHIBIT 2. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $1.6 million fewer contributions in total annual tax revenue, with $1.2 million of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts— Impoundment and Partial or Full Removal

Source: PSC analysis

Property Value Analysis

PSC compiled assessed and taxable values from the Iosco County Equalization Department for the tax (calendar) year 2022. In other studies of Consumers dams, PSC conducted a property analysis to estimate the impact of partial and/or full dam removal on properties adjacent to the pond. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

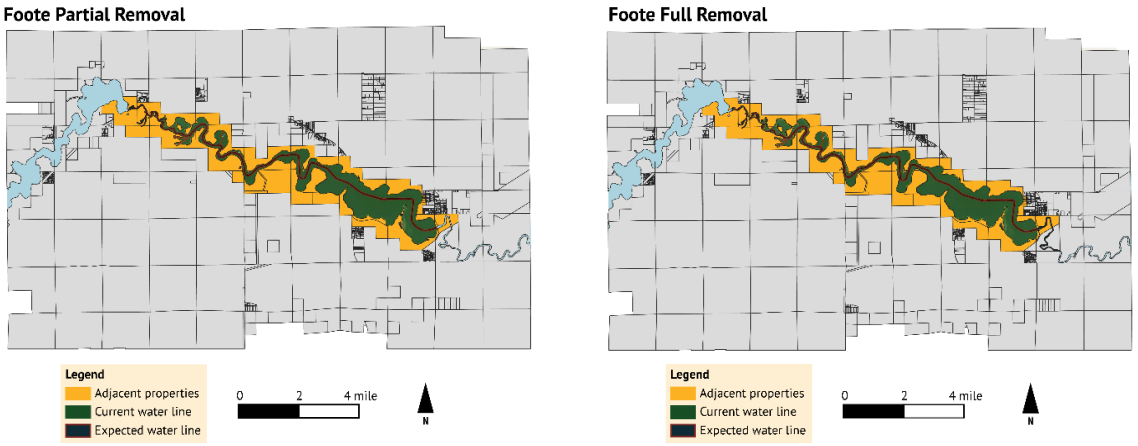
PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Foote Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background



Foote Dam is the easternmost of Consumers Energy's 13 hydroelectric dams. It is located in Oscoda Township, Iosco County, about seven miles west of Lake Huron and the unincorporated community of Oscoda. Foote Dam was completed in 1918. It is about 47 feet in height and about 4,100 feet in length. Huron National Forest is to the south and west of the impoundment, Foote Pond, which also offers recreational opportunities.

Environmental Context

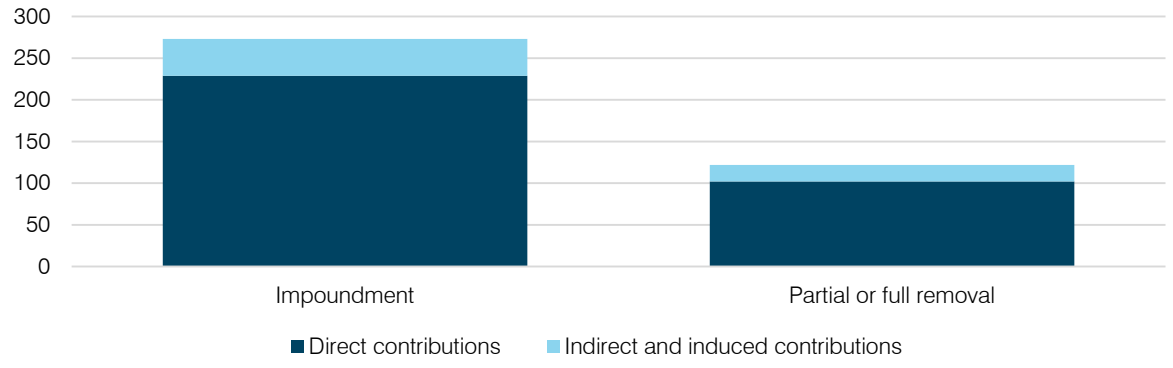
While no decision has been made on the Foote Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Where hydrologic conditions persist over time, wetlands will form. This will likely occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal. Exhibit 4 shows the projected shifts in water line and current impoundment-adjacent parcels.

EXHIBIT 4. Partial and Full Removal Parcel Analysis

The historic Foote Dam survey map indicated significant swamps and marshes within the existing impounded area, indicating the bottomlands have a propensity to form wetlands. However, the amount of sediment accumulation may impact wetland formation and thus the higher-elevation bottomlands would be expected to form as uplands once dewatered. Additionally, there are minimal wetlands adjacent to the impoundment, and it is less likely that wetlands would form on impounded sediments. If wetlands were to form, the most likely location is in the upper impoundment area where the impoundment narrows and there are wetlands closer to the impoundment. There is a high bluff on the north side of the impoundment, so wetlands are unlikely to form there. Wetlands may form along the adjacent wetland complexes or tributaries.

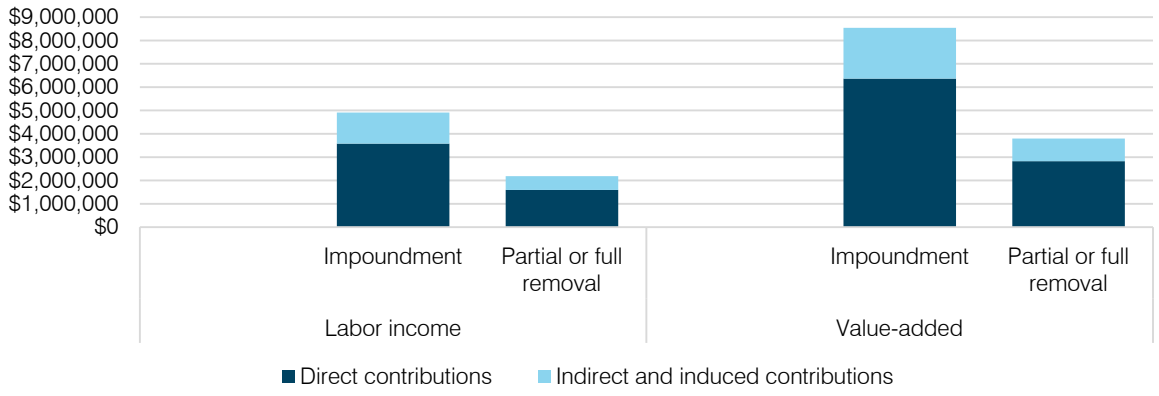
Economic Impact Analysis



To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis

After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC conducted a single analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state



sources, this analysis estimates the short-term economic impact of the full removal of the Foote Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 151 fewer jobs in the region and a $4.7 million reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

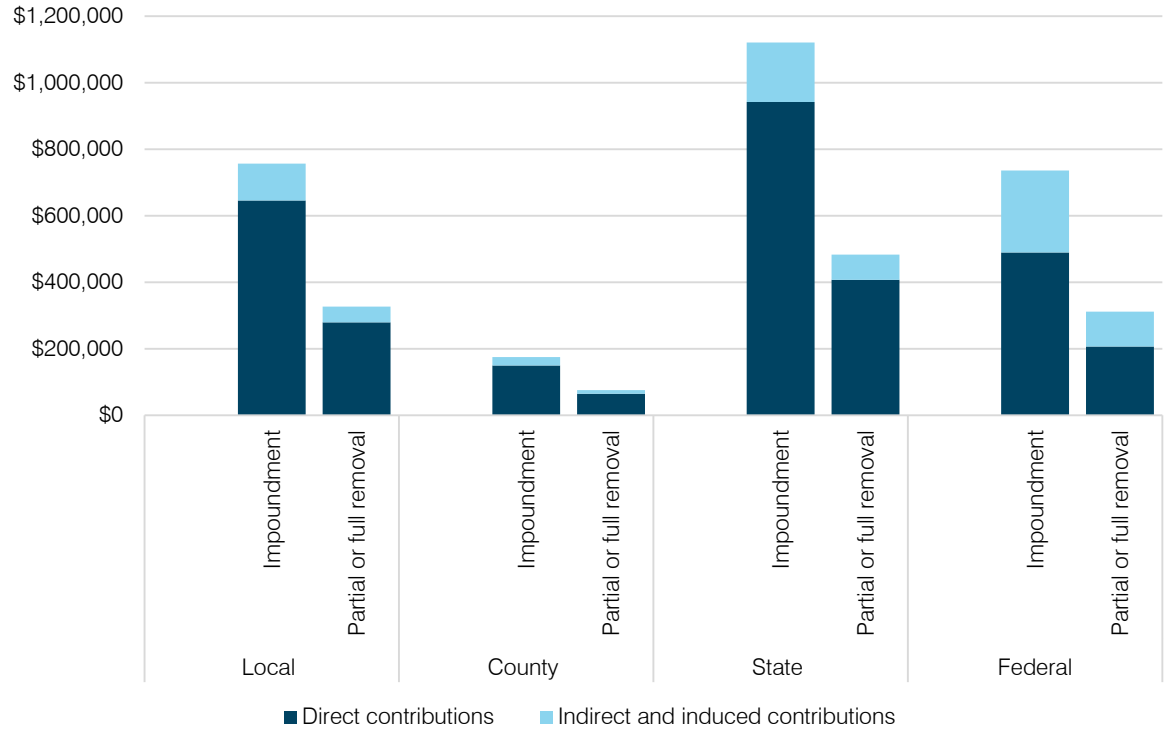

EXHIBIT 6. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will result in $1.6 million fewer contributions in total annual tax revenue, with $1.2 million of that reduction at the local, county, and state levels (Exhibit 7).

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Foote Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).

Property Value Analysis

PSC compiled assessed and taxable values from the Iosco County Equalization Department for the tax (calendar) year 2022. In other Consumers dam studies, PSC conducted a property analysis to estimate the impact of partial and full dam removal on properties adjacent to the pond. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Foote Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Foote Dam, which includes:

- A reduction of $4.7 million in gross regional product and 151 jobs
- A reduction of $1.6 million in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

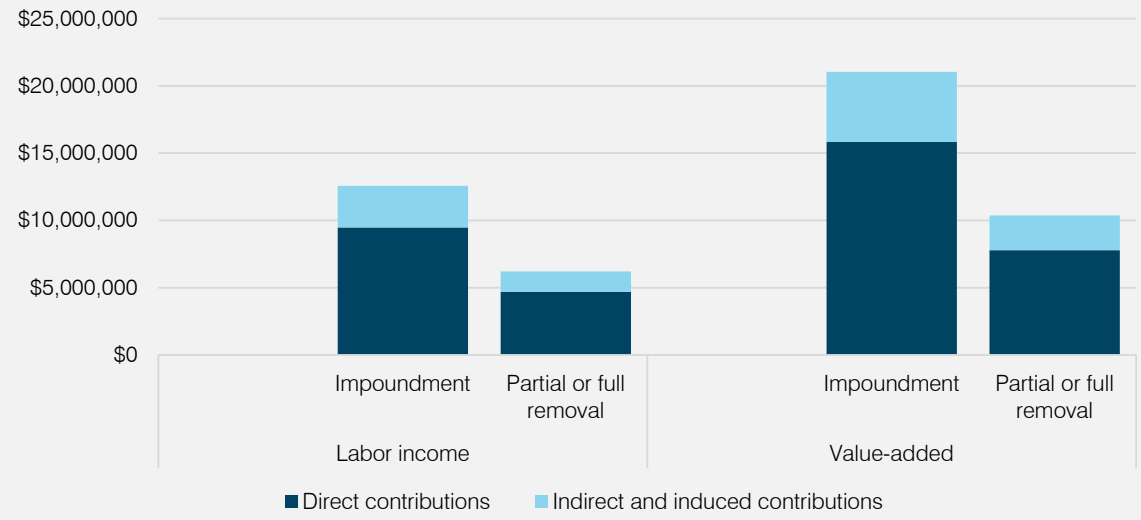
Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Hardy Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 251 fewer jobs in the region and a $10.7 million reduction in value-added to the local economy (Exhibits 1 and 2).

[1] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[2] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Property Analysis

Projecting changes in property values is a major component in calculating the economic impact of partially or fully removing the Hardy Dam. There are two related implications for the local economy. First, changes in the value of one's property affect household wealth. According to the Federal Reserve Board, the value of housing makes up approximately one-half of household wealth on average (Iacoviello 2011; Bostic et al. 2009). Accordingly, unexpected changes in property values can have significant implications for one's financial security. As households spend out of both income and wealth, a change in wealth has economic implications and may result in changes in household expenditures. While the potential for changes in household expenditures exists in what economists call the wealth effects on consumption. Wealth effects on consumption are relatively small as households seek to balance wealth accumulation and lifetime expenditures. Accordingly, this analysis sets out to document the changes in wealth as measured in the expected changes in residential housing values but makes no assumptions on changes in household purchasing behavior because of such wealth effects. Second, public revenues for local government units largely rely on property taxes levied based on the value of the community's underlying properties. Accordingly, a change in property values will have direct implications for government revenues necessary to support public services like the emergency services, local schools, parks, and others. Therefore, in addition to projecting changes in regional wealth, the property analysis will also project expected impacts on public revenues through residential property taxation.

Hardy Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background

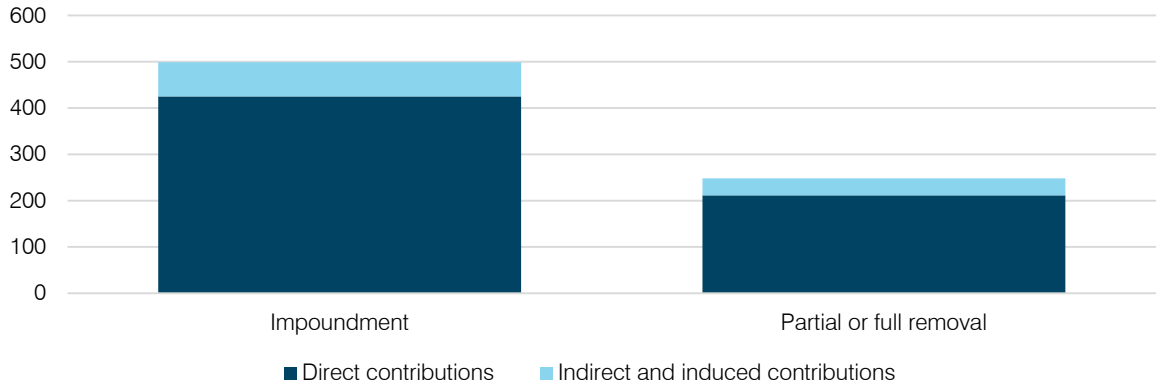
Hardy Dam is the tallest and largest generating unit of Consumers' 13 hydroelectric dams and was among the last to be built. Construction was completed in 1931. Hardy Dam is the largest earthen dam in North America east of the Mississippi River. The dam is 100 feet in height and 2,580 feet in length. Located in Big Prairie Township, Newaygo County, Hardy Dam is northwest of Croton Dam and southeast of Rogers Dam on the Muskegon River. Nearby communities include White Cloud in Newaygo County to the west and Stanwood and Morley in Mecosta County to the east. Big Prairie Township's population is approximately 2,600 individuals. The dam creates the 3,900 acre impoundment known as Hardy Dam Pond, which is more than twice the size of the next-largest impoundment at a Consumers dam.

Environmental Context

While no decision has been made on the Hardy Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Over time, wetlands will begin to take hold, forming where the hydrologic conditions persist for their creation. This transition likely will occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal.

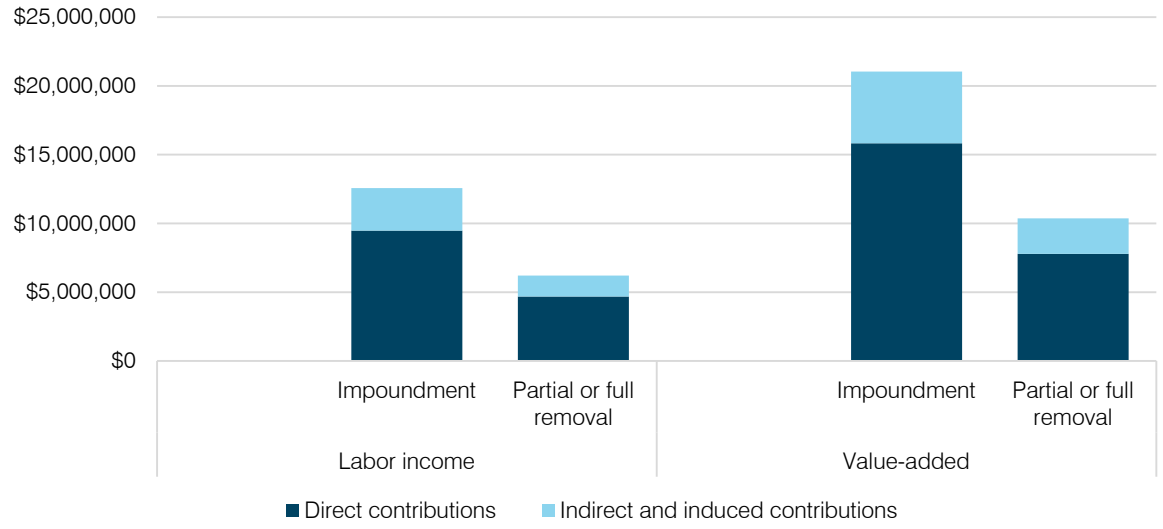
The historic survey maps for the Hardy Dam Pond are limited but indicate that larger areas of uplands are likely to form in the lower impoundment (near the current dam). There is propensity for wetland formation between the river bends in the lower impoundment unless specifically separated with impounded sediment fill. Based on the Michigan Natural Features Inventory (MNFI) wetland viewer, the upper impoundment would also likely have significant wetland formation where prolific wetland complexes have been identified. Given the impoundment's size, upland areas would be expected to form in the wider impoundment areas with selective wetland formation near tributaries, inside channel bends, and lower elevations within the restored topography.



Economic Impact Analysis

To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis



After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC conducted a single analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Hardy Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 251 fewer jobs in the region and a $10.7 million reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Full or Partial Removal

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Hardy Dam Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

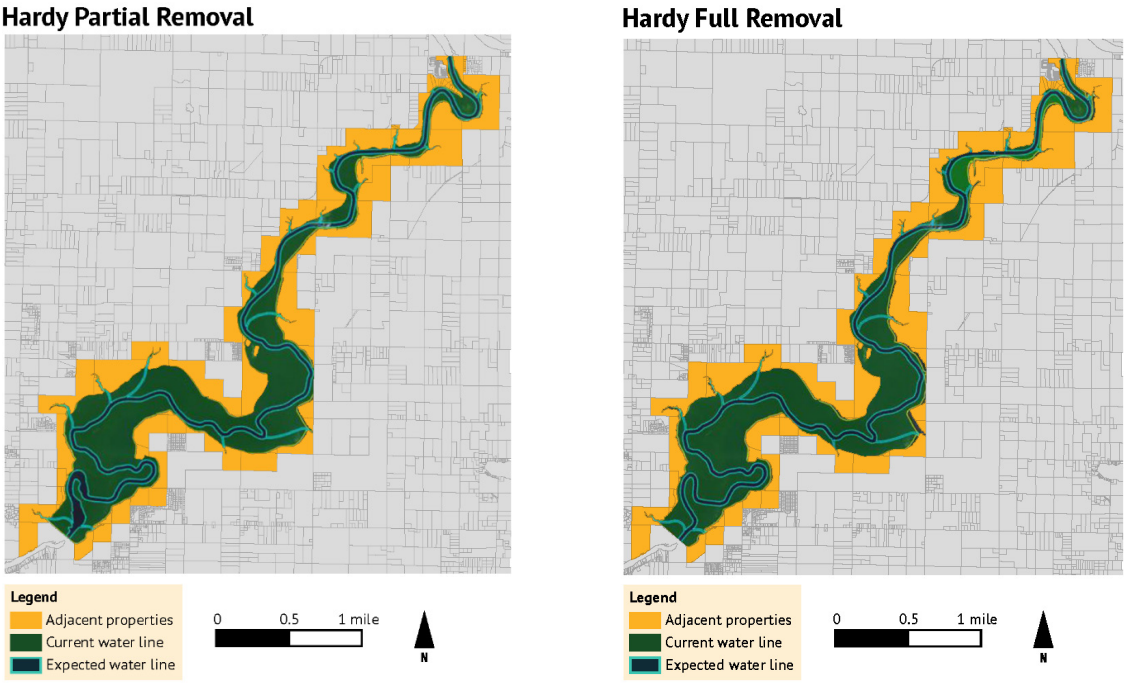
Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services



Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).

Property Value Analysis

Residential lots adjacent to the existing Hardy Dam Pond are limited to about 21 properties well away from the actual dam. Accordingly, the net amenity effect on these households is much less than if the properties were near the dam along the widest and deepest components of the impoundment. Exhibit 8 shows two maps of property plats around Hardy Dam Pond, one depicting the extent of the expected water line under a partial dam removal and one showing the same under a full dam removal. As the expected extent of the water under the two dam removal scenarios are equal, the expected effect on property values should be equal between the two outcomes.

EXHIBIT 8. Partial and Full Removal Parcel Analysis

The results of PSC analysis on the potential net change in property values and associated annual property tax impact are highlighted in Exhibit 9.

EXHIBIT 9. Property Analysis Results

	Removal
Number of Properties Analyzed	21
Expected Net Property Value Impacts	
Assessed value	-$118,751
Market value[3]	-$237,503
Expected Net Property Tax Revenue Impacts[4]	
Taxable value	-$76,506
Tax revenues	-$2,740
Average millage	35.813

[3] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[4] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Hardy Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Hardy Dam, which includes:

- A reduction of $10.7 million in gross regional product and 251 jobs
- A reduction of $3.1 million in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

The partial or full removal of the dam will also impact adjacent property values, including:

- A reduction of $237,503 in market value to adjacent properties
- A reduction in $2,740 in local and state property tax revenue due to the decreased market value

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

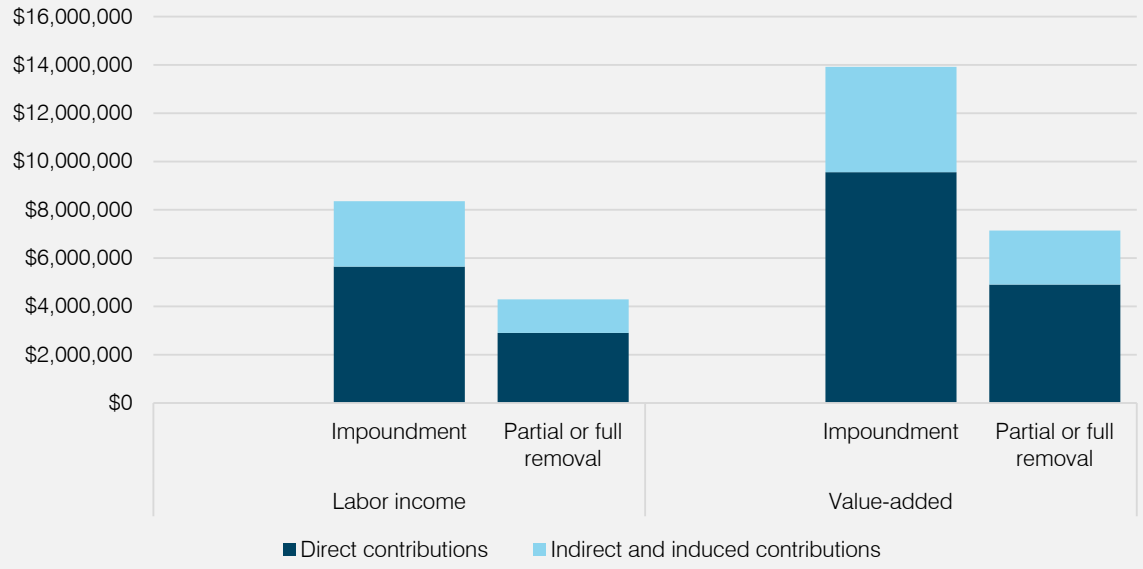
Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Hodenpyl Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 167 fewer jobs in the region and a $6.8 million reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

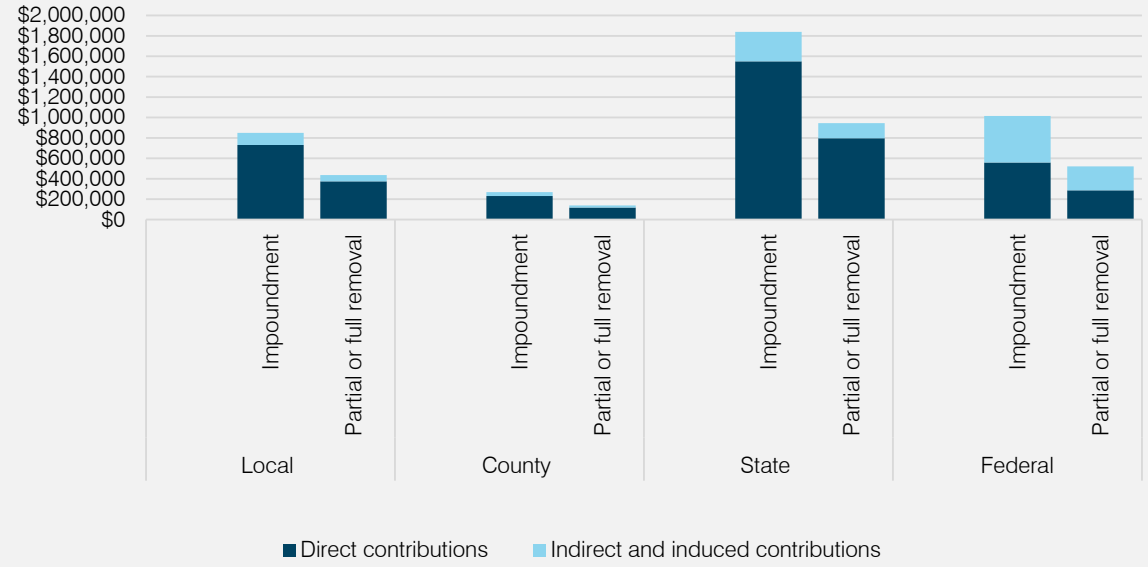


EXHIBIT 2. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $1.9 million fewer contributions in total annual tax revenue, with $1.4 million of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts— Impoundment and Partial or Full Removal

Source: PSC analysis

Property Value Analysis

PSC compiled assessed and taxable values from the Wexford County Equalization Department for the tax (calendar) year 2022. In other Consumers dam studies, PSC conducted a property analysis to estimate the impact of partial and full dam removal on impoundment-adjacent properties. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

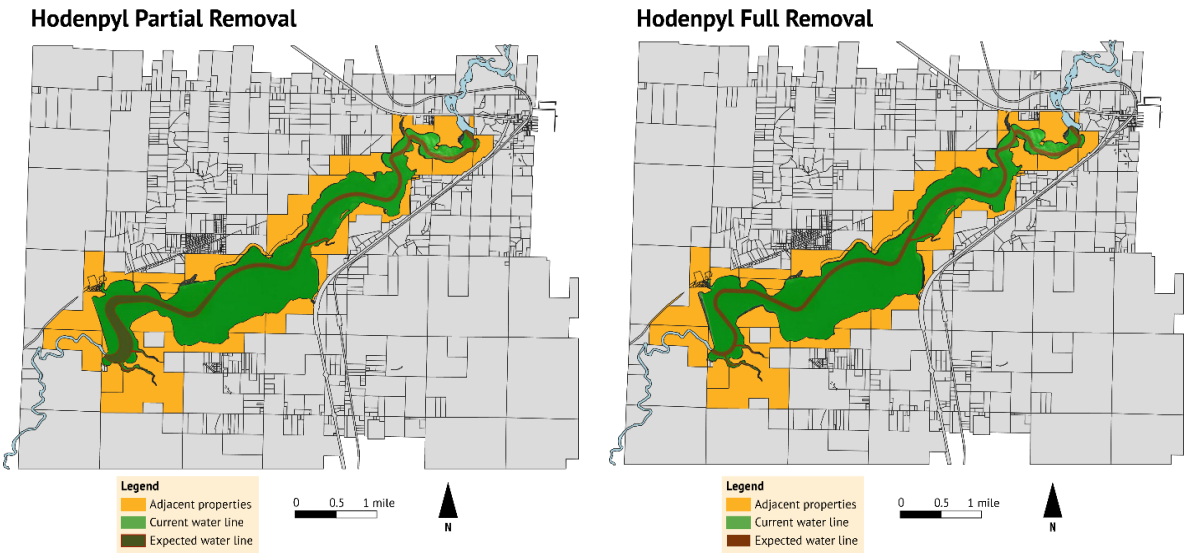
PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Hodenpyl Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background



Completed in 1925, Hodenpyl Dam is one of two dams on the Manistee River. Located just east of the Manistee-Wexford County line, the Hodenpyl Dam is situated at the edge of the Manistee National Forest in Springville Township, which has a population of about 1,800. The dam creates an impoundment, Hodenpyl Dam Pond, that covers about 1,798 acres. The dam has the third largest generating capacity of Consumers' 13 hydroelectric dams.

Environmental Context

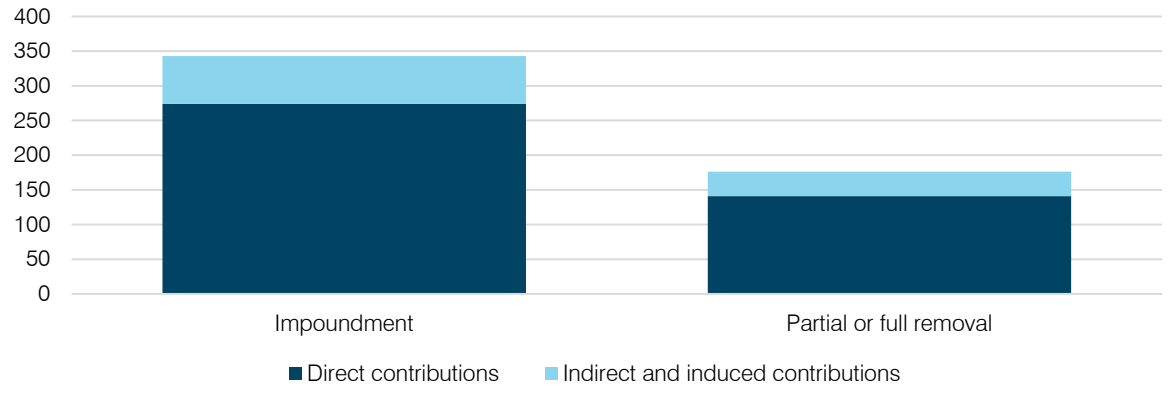
While no decision has been made on the Hodenpyl Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Where hydrologic conditions persist over time, wetlands will form. This transition likely will occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal. Exhibit 4 shows the projected shifts in water line and current impoundment-adjacent parcels.

EXHIBIT 4. Partial and Full Removal Parcel Analysis

Historic Hodenpyl Dam survey maps show a few wetland indicators within the impoundment outside of the immediate floodplain areas, which suggests that upland habitat formation in this impoundment is likely. A partial dam removal might produce conditions where wetland habitat types could form around the boundaries of the reduced impoundment area, particularly along the inside of restored river channel bends and where tributaries enter the impoundment. Additionally, if there are any lower areas in the post dam removal topography, those areas may also experience wetland formation. Generally, it is expected a large majority of the current impounded area could convert to upland habitat.

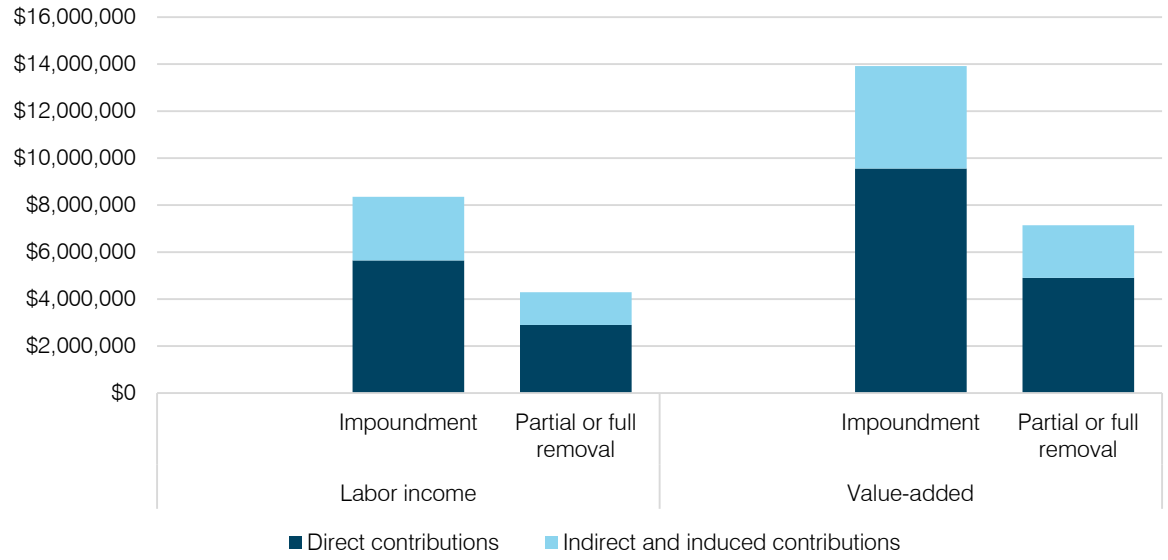
Economic Impact Analysis



To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis

After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC conducted a single analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state



sources, this analysis estimates the short-term economic impact of the full removal of the Hodenpyl Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 167 fewer jobs in the region and a $6.8 million reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Hodenpyl Dam Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).

Property Analysis

PSC compiled assessed and taxable values from the Wexford County Equalization Department for the tax (calendar) year 2022. In other Consumers dam studies, PSC conducted a property analysis to estimate the impact of partial and full dam removal on impoundment-adjacent properties. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Hodenpyl Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Hodenpyl Dam, which includes:

- A reduction of $6.8 million in gross regional product and 167 jobs
- A reduction of $1.9 million in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

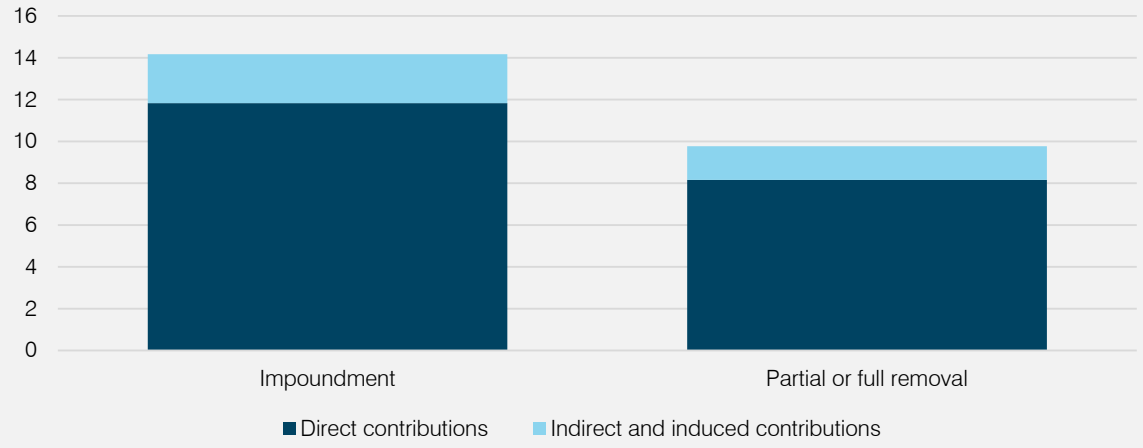
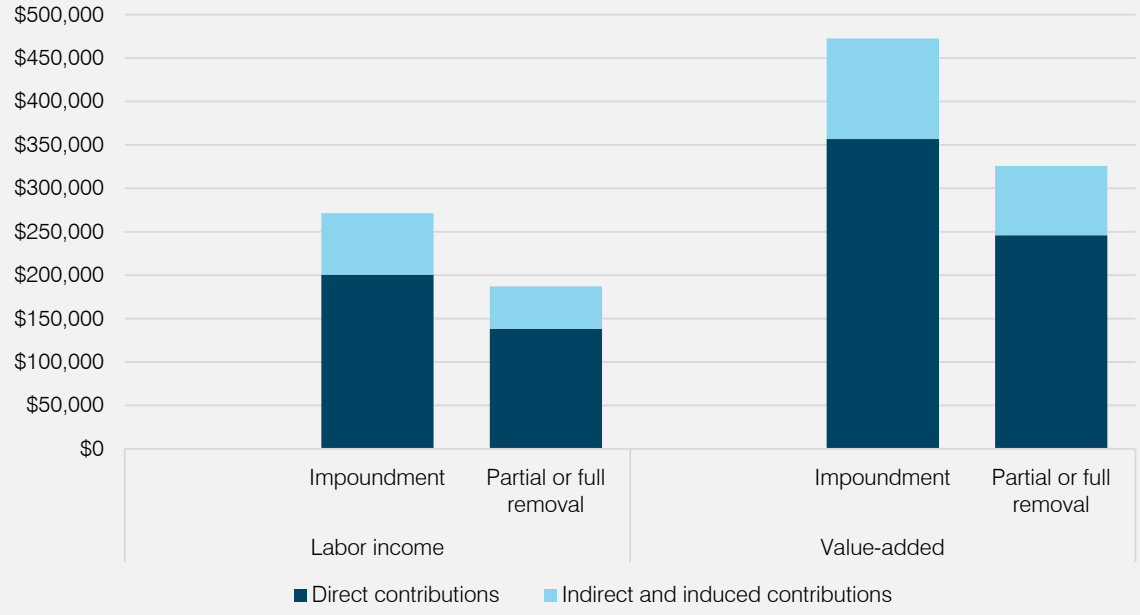
APPENDIX A: METHODOLOGY 21



Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Loud Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 4 fewer jobs in the region and a $146,927 reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

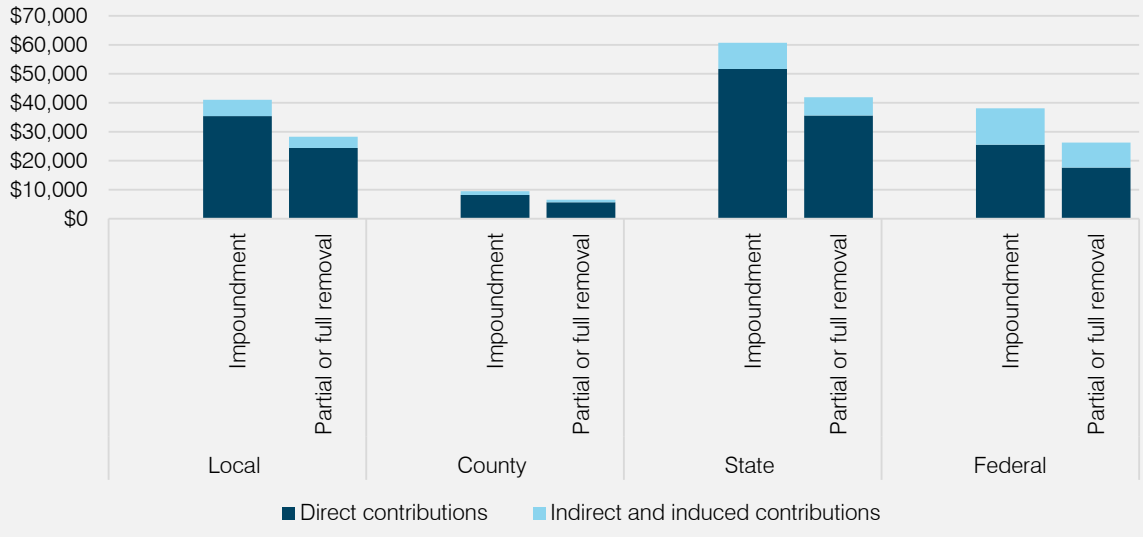


EXHIBIT 2. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $46,341 fewer contributions in total annual tax revenue, with $34,509 of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts— Impoundment and Partial or Full Removal

Source: PSC analysis

Property Value Analysis

PSC compiled assessed and taxable values from the Iosco County Equalization Department for the tax (calendar) year 2022. In other studies of Consumers dams, PSC conducted a property analysis to estimate the impact of partial and/or full dam removal on properties adjacent to the pond. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

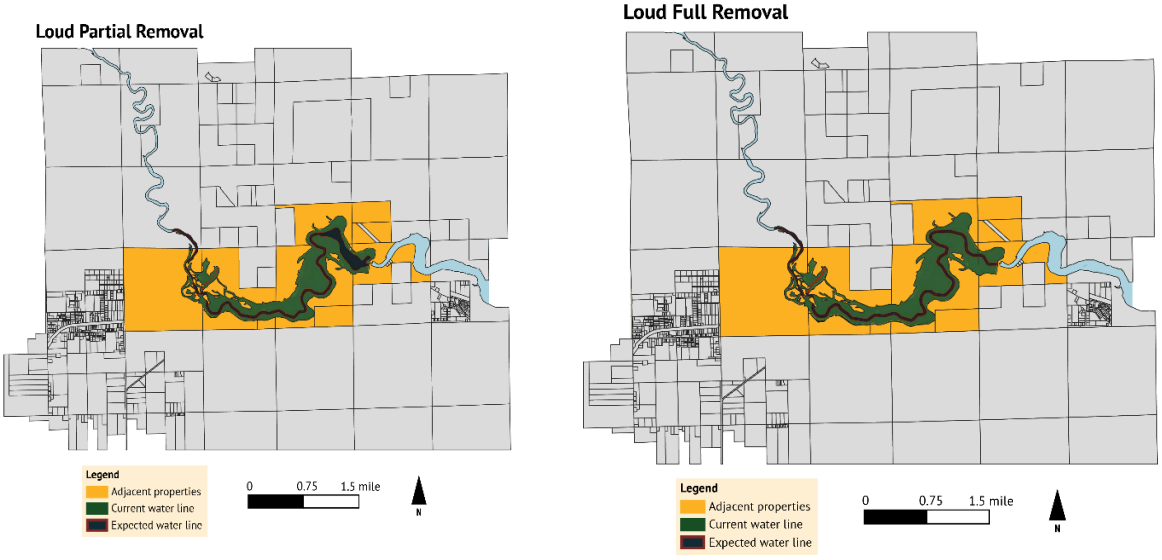
PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Loud Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background



Loud Dam is located in Oscoda Township, Iosco County, about nine miles south of the town of Glennie and immediately west of Five Channels Dam. It is one of six Consumers hydroelectric dams on the Au Sable River. Oscoda Township is home to about 6,800 individuals, just over a quarter of the county population. Loud Dam is about 40 feet tall and 2,180 feet in length. The resulting impoundment, Loud Dam Pond, covers an area of approximately 790 acres. Loud Dam was completed in 1913.

Environmental Context

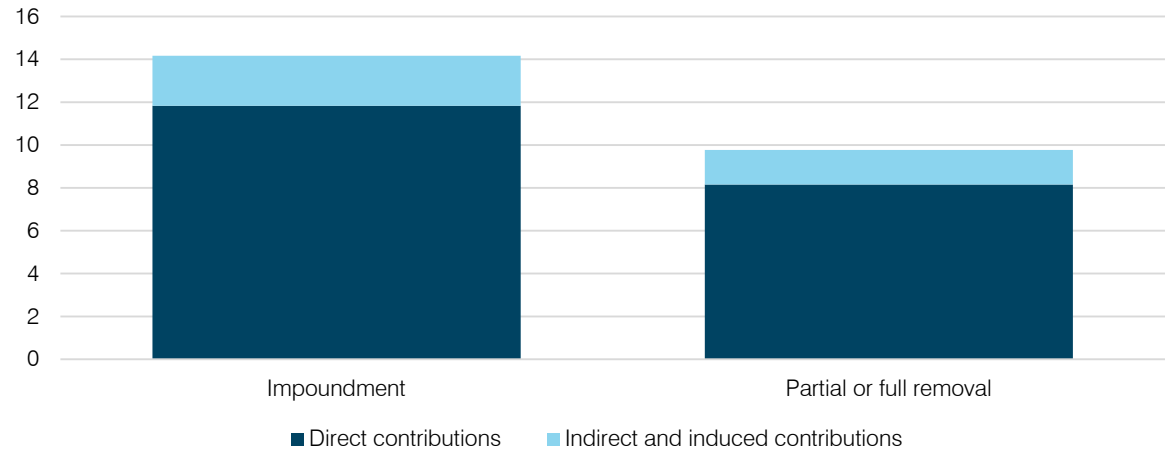
While no decision has been made on the Loud Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Where hydrologic conditions persist over time, wetlands will form. This will likely occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal. Exhibit 4 shows the projected shifts in water line and current impoundment-adjacent parcels.

EXHIBIT 4. Partial and Full Removal Parcel Analysis

There would likely be minimal differences in wetland and upland habitat formation following the partial or full dam removal. The MNFI wetland viewer map indicates a significant wetland complex will likely form north of and immediately adjacent to the dam impoundment. This wetland complex, the tributaries entering the impoundment, and the smaller wetland formation to the south of the lower impoundment near the dam are all likely to influence wetland formation within the dam impoundment under both partial and full dam-removal scenarios. These habitats may form on the existing wetlands adjacent to the impoundment, tributaries, and the restored river channel alignment.

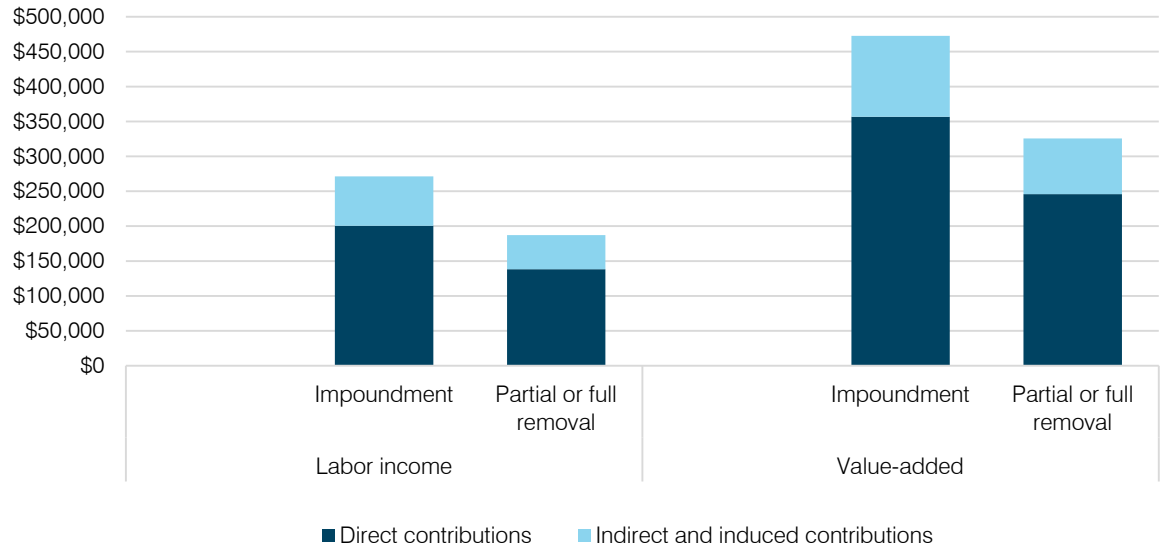
Economic Impact Analysis



To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis

After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC conducted a single analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state



sources, this analysis estimates the short-term economic impact of the full removal of the Loud Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 4 fewer jobs in the region and a $146,927 reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

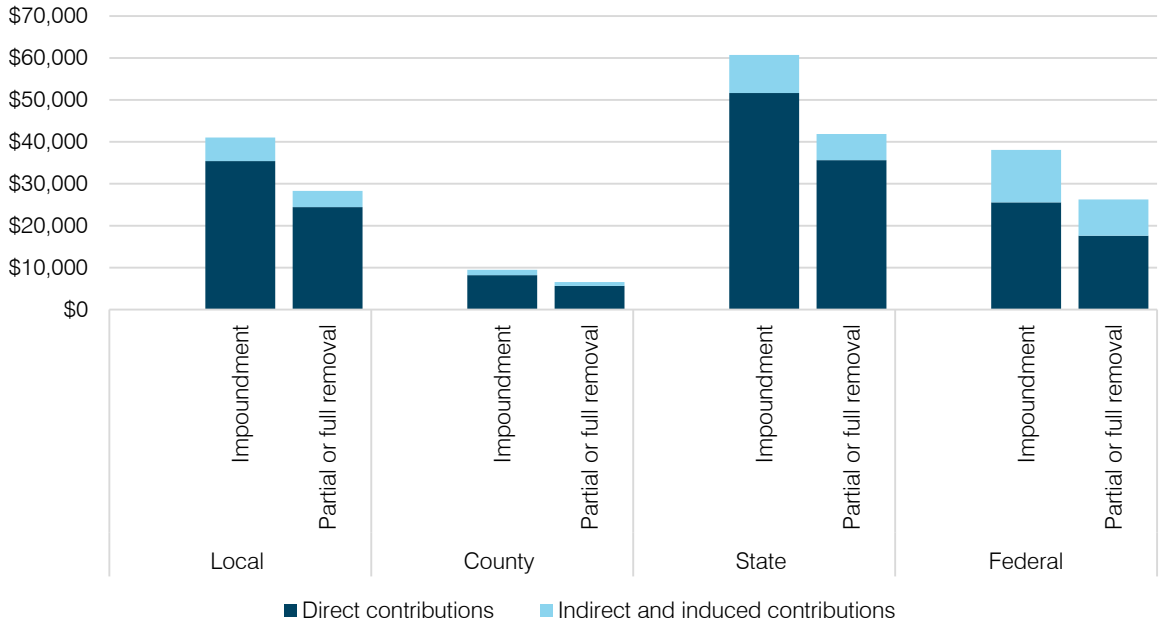


EXHIBIT 6. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will result in $46,341 fewer contributions in total annual tax revenue, with $34,509 of that reduction at the local, county, and state levels (Exhibit 7).

EXHIBIT 7. Tax Impacts—Impoundment and Partial or Full Removal

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Loud Dam Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Loud Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Loud Dam, which includes:

- A reduction of $146,927 in gross regional product and 4 jobs
- A reduction of $46,341 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

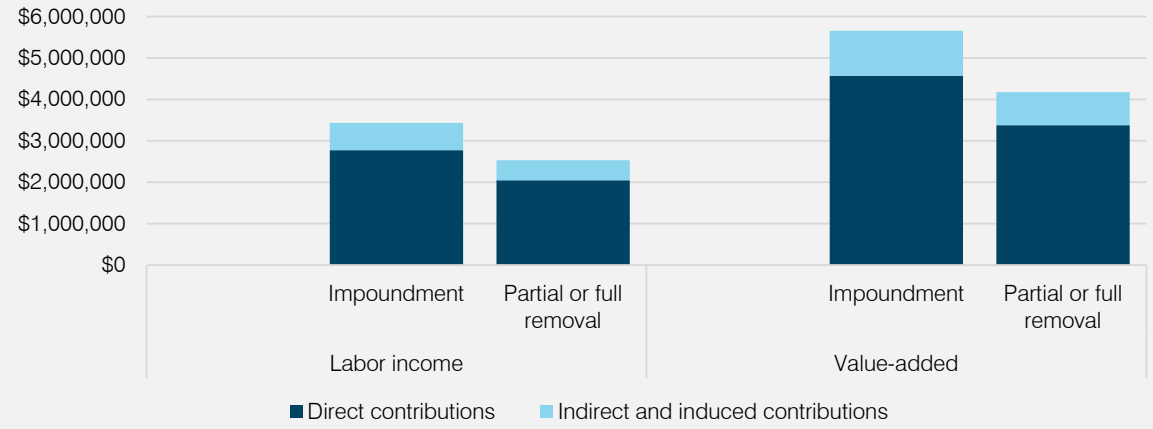
Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's Methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Mio Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 39 fewer jobs in the region and a $1.5 million reduction in value-added to the local economy (Exhibits 1 and 2).

Property Value Analysis

To better understand the dam removal impacts on residential property values, PSC analyzed the potential net change in property values and associated annual property tax impact (Exhibit 4).

EXHIBIT 4. Property Analysis Results

	Removal
Number of Properties Analyzed	30
Expected Net Property Value Impacts	
Assessed value	-$344,704
Market value[1]	-$689,408
Expected Net Property Tax Revenue Impacts[2]	
Taxable value	-$288,683
Tax revenues	-$9,906
Average millage	34.315

Sources: Oscoda County Equalization Department, PSC analysis

[1] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[2] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's Methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g., partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Property Analysis

Projecting changes in property values is a major component in calculating the economic impact of partially or fully removing the Mio Dam. There are two related implications for the local economy. First, changes in the value of one's property affect household wealth. According to the Federal Reserve Board, the value of housing makes up approximately one-half of household wealth on average (Iacoviello 2011; Bostic et al. 2009). Accordingly, unexpected changes in property values can have significant implications for one's financial security. As households spend out of both income and wealth, a change in wealth has economic implications and may result in changes in household expenditures. While the potential for changes in household expenditures exists in what economists call the wealth effects on consumption. Wealth effects on consumption are relatively small as households seek to balance wealth accumulation and lifetime expenditures. Accordingly, this analysis sets out to document the changes in wealth as measured in the expected changes in residential housing values but makes no assumptions on changes in household purchasing behavior because of such wealth effects. Second, public revenues for local government units largely rely on property taxes levied based on the value of the community's underlying properties. Accordingly, a change in property values will have direct implications for government revenues necessary to support public services like the emergency services, local schools, parks, and others. Therefore, in addition to projecting changes in regional wealth, the property analysis will also project expected impacts on public revenues through residential property taxation.

Mio Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background

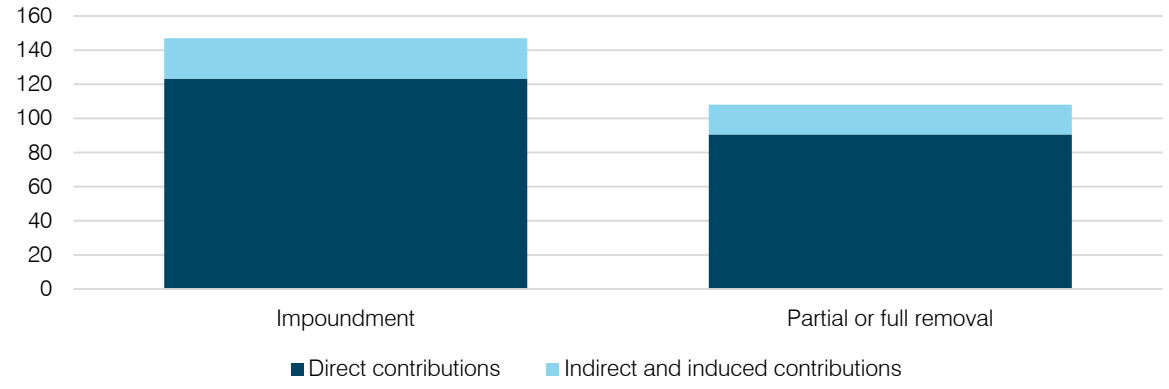
Mio Dam is located in Big Creek Township, just north of Mio, a small unincorporated community in Oscoda County. The county population is approximately 8,300. Completed in 1916, the Mio Dam is about 20 miles northwest of the Loud Dam. It is one of six Consumers hydroelectric dams on the Au Sable River in northwestern Michigan. Mio Dam is 38 feet high and about 2,120 feet long. The impoundment, Mio Pond, is approximately 661 acres in area.

Environmental Context

While no decision has been made on the Mio Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Where hydrologic conditions persist over time, wetlands will form. This transition likely will occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and the final topographic surface after partial or full dam removal.

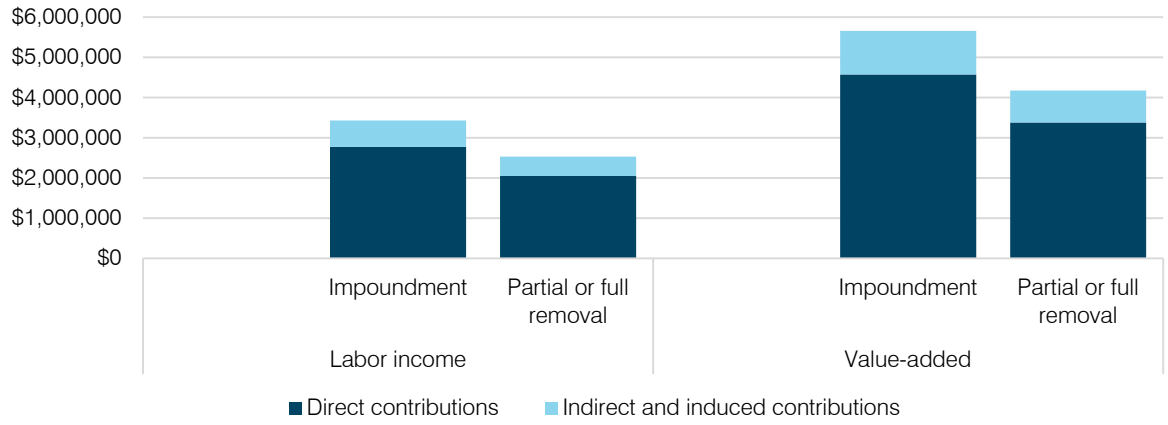
The historic survey map of the Mio Dam impoundment indicated cedar swamps were prevalent on the southern portion of the middle impoundment. There are a few areas where wetlands would be likely to be more prominent, such as where tributaries enter the impoundment or wetland complexes are present adjacent to the impoundment. Otherwise, the remaining areas of the impoundment could potentially form upland habitat. The interpretation of habitat formation is expected to be similar for the partial and full dam removal scenarios.



Economic Impact Analysis

To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis



After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. As seen in Exhibit 8, a partial removal would still leave a substantial impoundment near the dam, but unless recreational asset managers invest in extending water access points, there will still be significant impacts on site usage. As detailed in the Methodology section of this report, PSC analysis does not make assumptions about what actions individuals, businesses, or organizations would take in response to a partial or full dam removal, so the results of a partial dam removal analysis are likely to be similar to those of a full dam removal scenario. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Mio Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 39 fewer jobs in the region and a $1.5 million reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both partial and full removal scenarios, but in some cases, including at Mio Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

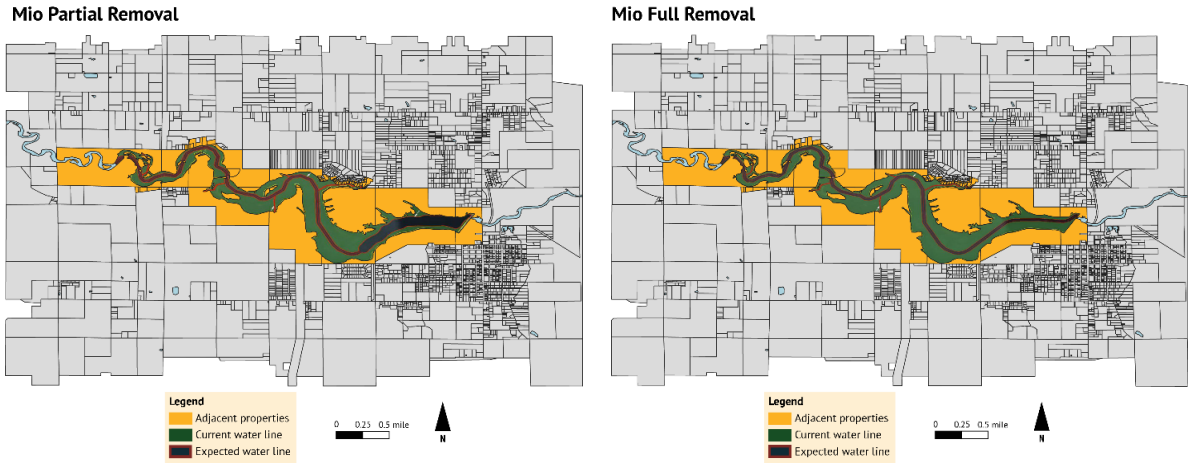
As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.



While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).

Property Value Analysis

Because the residential lots adjacent to Mio Pond include 30 properties well away from the actual dam, the upstream water footprint for both partial and full dam removal largely looks the same where the residential properties exist (see Exhibit 8). Residential property values and property tax revenues are likely to be the same under both dam modification options.

PSC determined the potential net change in residential property values and associated annual property tax revenues, highlighted in Exhibit 9. The collective loss in market value, estimated from assessed property values, is $689,408. As taxable and market values differ, the reduction in residential tax revenues is expected to be about $9,906.

EXHIBIT 8. Partial and Full Removal Parcel Analysis

The results of PSC analysis on the potential net change in property values and associated annual property tax impact are highlighted in Exhibit 9.

EXHIBIT 9. Property Analysis Results

	Partial/Full Removal
Number of Properties Analyzed	30
Expected Net Property Value Impacts	
Assessed value	-$344,704
Market value[3]	-$689,408
Expected Net Property Tax Revenue Impacts[4]	
Taxable value	-$288,683
Tax revenues	-$9,906
Average millage	34.315

Sources: Oscoda County Equalization Department, PSC analysis

[3] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[4] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Mio Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Mio Dam, which includes:

- A reduction of $1.5 million in gross regional product and 39 jobs
- A reduction of $897,308 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

The partial or full removal of the dam will also impact adjacent property values, contributing:

- A reduction of $689,408 in market value to adjacent properties
- A reduction in $9,906 in local and state property tax revenue due to the decreased market value

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

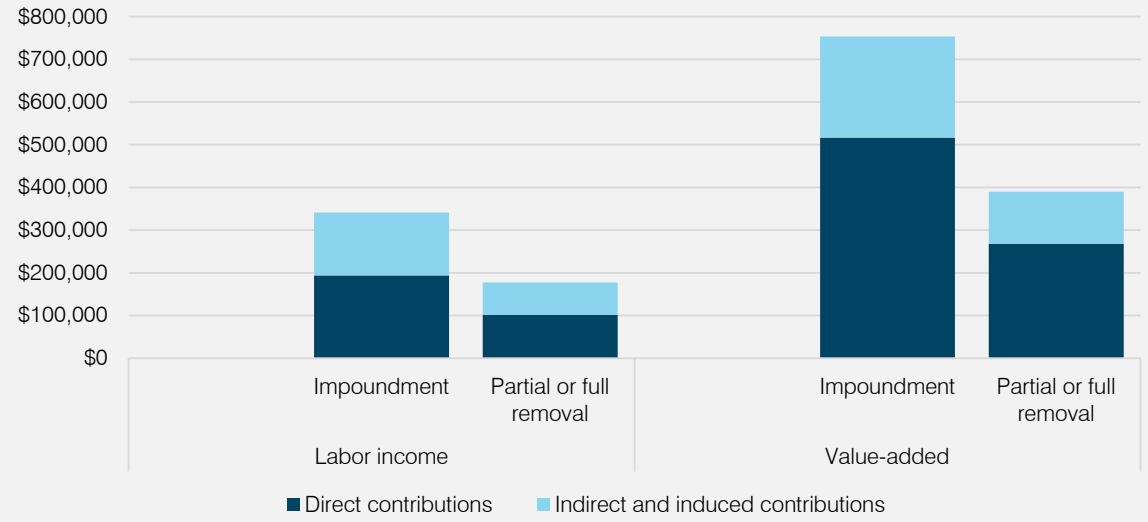
Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. After reviewing maps of the area, PSC conducted a single recreational analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Rogers Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 11 fewer jobs in the region and a $363,395 reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

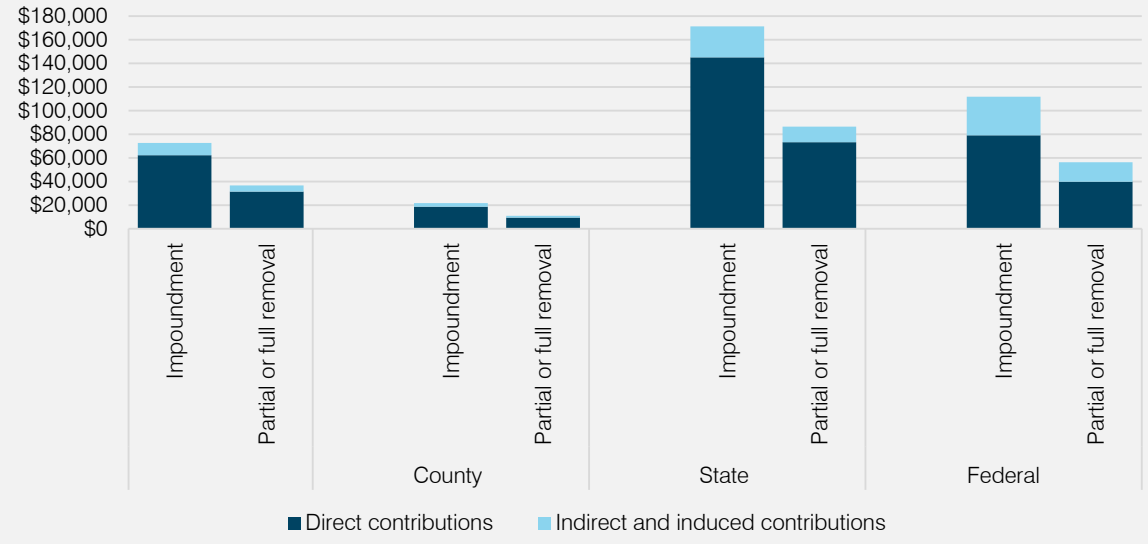


EXHIBIT 2. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $110,316 fewer contributions in total annual tax revenue, with $93,150 of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

Property Value Analysis

To better understand the dam removal impacts on residential property values, PSC analyzed the potential net change in property values and associated annual property tax impact (Exhibit 4).

EXHIBIT 4. Property Analysis Results

	Partial Removal	Full Removal
Number of Properties Analyzed	475	475
Expected Net Property Value Impacts		
Assessed value	-$3,354,871	-$6,384,083
Market value[1]	-$6,709,742	-$12,768,166
Expected Net Property Tax Revenue Impacts[2]		
Taxable value	-$2,873,793	-$3,163,688
Tax revenues	-$95,763	-$104,423
Average millage	33.323	33.323

Sources: Mecosta County Equalization Department, PSC analysis

[1] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[2] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Property Analysis

Projecting changes in property values is a major component in calculating the economic impact of partially or fully removing the Rogers Dam. There are two related implications for the local economy. First, changes in the value of one's property affect household wealth. According to the Federal Reserve Board, the value of housing makes up approximately one-half of household wealth on average (Iacoviello 2011; Bostic et al. 2009). Accordingly, unexpected changes in property values can have significant implications for one's financial security. As households spend out of both income and wealth, a change in wealth has economic implications and may result in changes in household expenditures. While the potential for changes in household expenditures exists in what economists call the wealth effects on consumption. Wealth effects on consumption are relatively small as households seek to balance wealth accumulation and lifetime expenditures. Accordingly, this analysis sets out to document the changes in wealth as measured in the expected changes in residential housing values but makes no assumptions on changes in household purchasing behavior because of such wealth effects. Second, public revenues for local government units largely rely on property taxes levied based on the value of the community's underlying properties. Accordingly, a change in property values will have direct implications for government revenues necessary to support public services like the emergency services, local schools, parks, and others. Therefore, in addition to projecting changes in regional wealth, the property analysis will also project expected impacts on public revenues through residential property taxation.

Rogers Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background

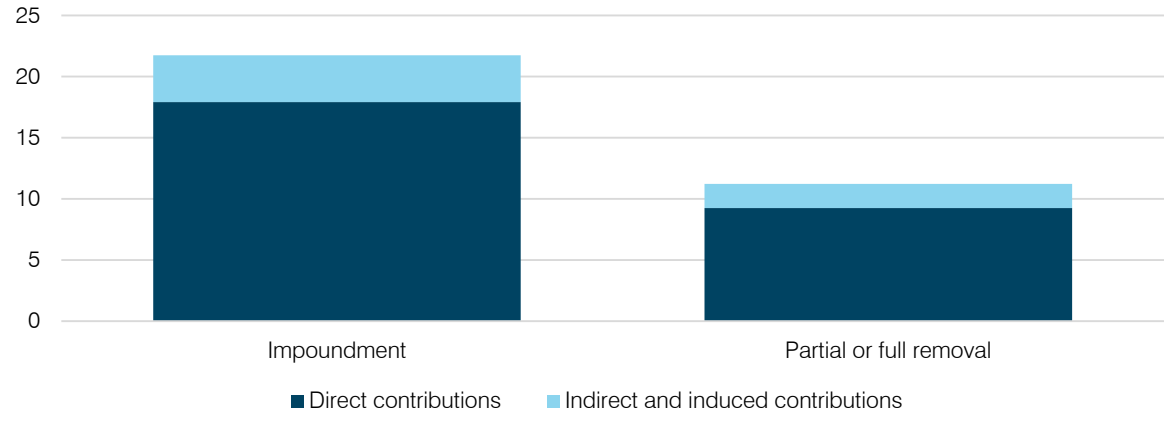
Completed in 1906, Rogers is Consumers Energy's oldest hydroelectric dam. It is located in Mecosta Township, Mecosta County, about six miles south of Big Rapids. Mecosta Township has approximately 2,700 residents, while Big Rapids—home to Ferris State University—has a population of approximately 9,000. The earthen embankment is 800 feet wide and about 40 feet tall. The impoundment, Rogers Dam Pond, is approximately 449 acres in area and provides residents and visitors with recreational opportunities, including boating and fishing.

Environmental Context

While no decision has been made on the Rogers Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Over time, wetlands will begin to take hold, forming where the hydrologic conditions persist for their creation. This transition likely will occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal.

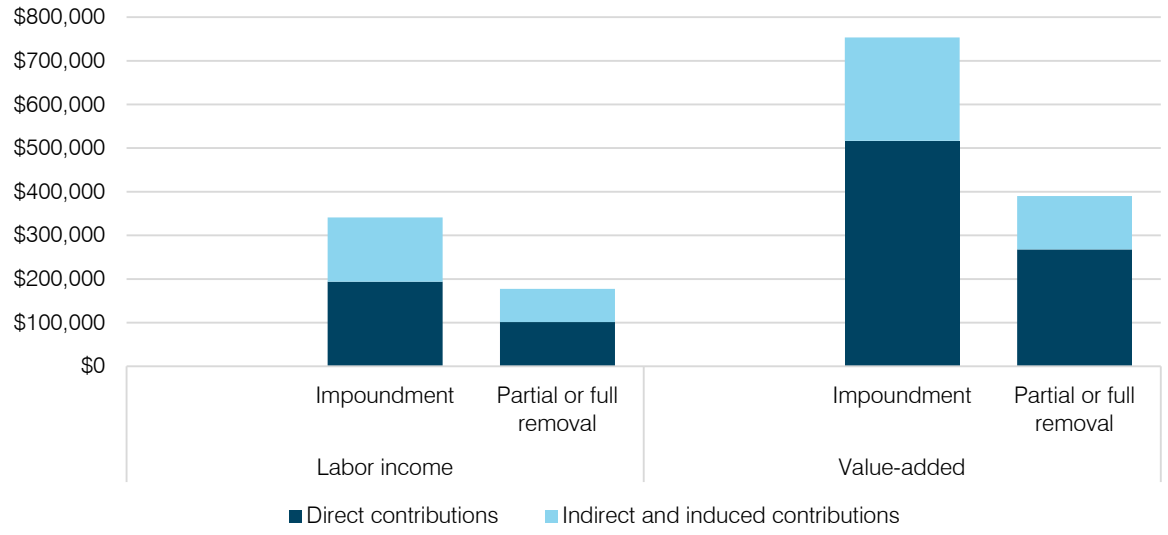
The historic survey map of the Rogers Dam impoundment does not indicate any marsh or swamp land types. It did note significant areas of "timbers," which we interpreted as uplands. Combining the historic survey map with the MNFI wetland map viewer indicates that wetlands may form along inside bends of the restored river channel, near wetland complexes adjacent to the existing impoundment, and along tributaries entering the impoundment. A partial dam removal scenario would likely have similar delineations of upland and wetland habitat, with the potential of slightly more wetlands immediately adjacent to the small impoundment. Wetland formation in that scenario would be highly dependent on the final topographic grading within the former impounded area.



Economic Impact Analysis

To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis



After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC conducted a single recreational analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Rogers Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 11 fewer jobs in the region and a $363,395 reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

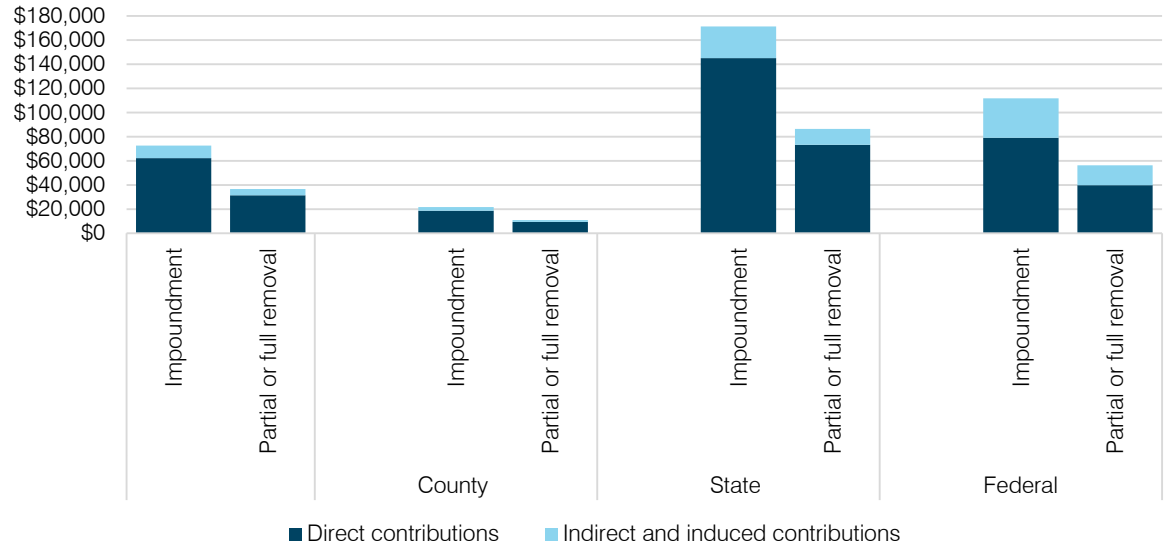


EXHIBIT 6. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $110,316 fewer contributions in total annual tax revenue, with $93,150 of that reduction at the local, county, and state levels (Exhibit 3).

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Rogers Dam Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

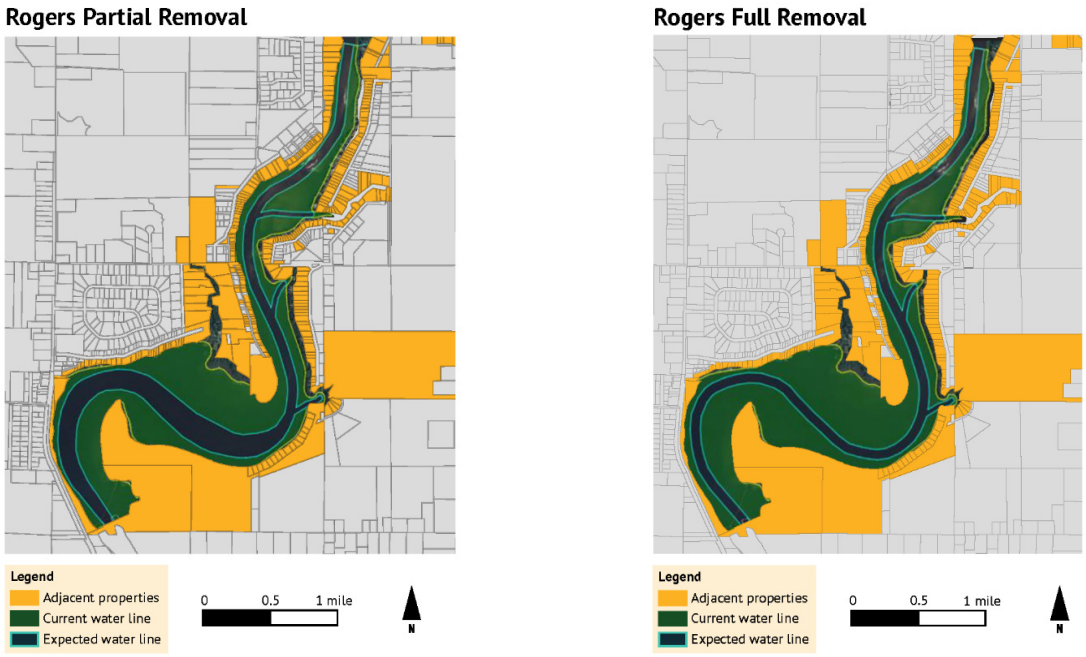
As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.



While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).

Property Value Analysis

Residential lots adjacent to the existing impoundment include 492 properties around the Roger Dam Pond. To what extent residential property values would be affected by a partial or full dam removal depends on a property's proximity to the resulting water's edge. Exhibit 8 shows two maps of residential property plats around Rogers Dam Pond, one depicting the extent of the expected water line under a partial dam removal and one showing the same under a full dam removal. The expected extant of the water body after dam modification is shown by the green and blue insert. All other points along the river system are assumed to be invariant between the two scenarios and from the current relationship with the water system.

PSC determined the potential net change in property values and associated annual property tax impact, highlighted in Exhibit 9. Accordingly, the relatively small impoundment expected with a partial dam removal will provide waterfront access to more properties than under a full removal. Because more lots will have greater water proximity than with full removal, the partial-removal scenario would be expected to have a lesser overall negative effect on overall residential property values and annual residential property tax revenues. As Exhibit 9 indicates, 475 impoundment-adjacent properties will experience a cumulative reduction in market values of $6.7 million and $12.8 million under the partial and full dam removal scenarios, respectively. This is expected to reduce annual residential property tax revenues by about $95,763 for a partial removal or $104,423 for a full removal.

EXHIBIT 8. Partial and Full Removal Parcel Analysis

The results of PSC analysis on the potential net change in property values and associated annual property tax impact are highlighted in Exhibit 9.

EXHIBIT 9. Property Analysis Results

	Partial Removal	Full Removal
Number of Properties Analyzed	475	475
Expected Net Property Value Impacts		
Assessed value	-$3,354,871	-$6,384,083
Market value[3]	-$6,709,742	-$12,768,166
Expected Net Property Tax Revenue Impacts[4]		
Taxable value	-$2,873,793	-$3,163,688
Tax revenues	-$95,763	-$104,423
Average millage	33.323	33.323

Sources: Mecosta County Equalization Department, PSC analysis

[3] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[4] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Rogers Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Rogers Dam, which includes:

- A reduction of $363,395 in gross regional product and 11 jobs
- A reduction of $110,316 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

The partial removal of the dam will also impact adjacent property values, including:

- A reduction of $6,709,742 in market value to adjacent properties
- A reduction in $95,763 in local and state property tax revenue due to the decreased market value

The full removal of the dam will also impact adjacent property values, including:

- A reduction of $12,768,166 in market value to adjacent properties
- A reduction in $104,426 in local and state property tax revenue due to the decreased market value

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

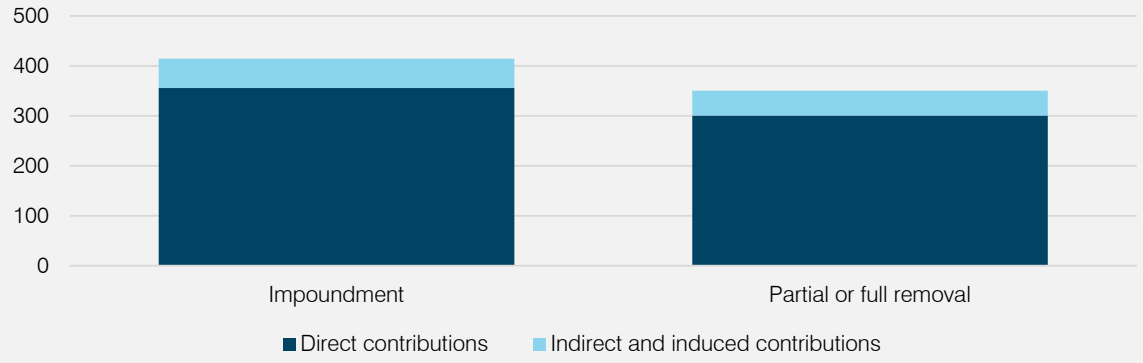
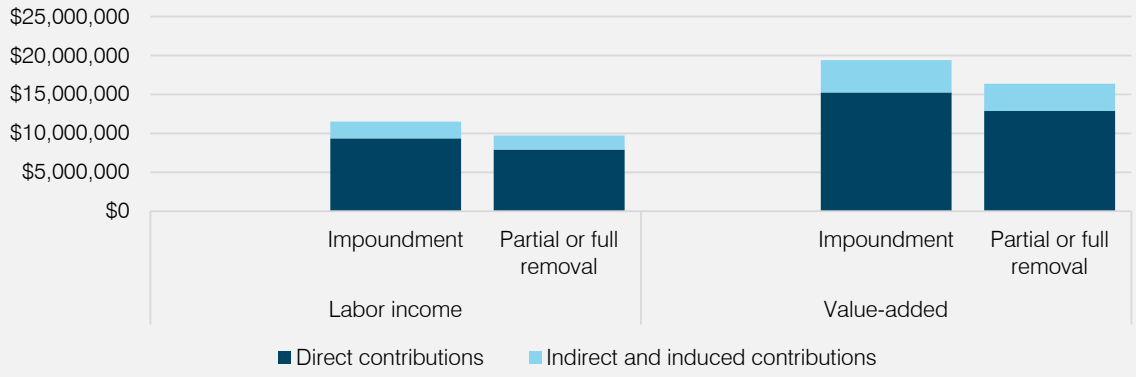
APPENDIX A: METHODOLOGY 21



Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Tippy Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 64 fewer jobs in the region and a $3 million reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

These estimated shifts in recreational activity will also result in $862,909 fewer contributions in total annual tax revenue, with $580,561 of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts— Impoundment and Partial or Full Removal

Source: PSC analysis

Property Value Analysis

PSC compiled assessed and taxable values from the Manistee County Equalization Department and the Wexford County Equalization Department for the tax (calendar) year 2022. In other Consumers dam studies, PSC conducted a property analysis to estimate the impact of partial and full dam removal on impoundment-adjacent properties. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

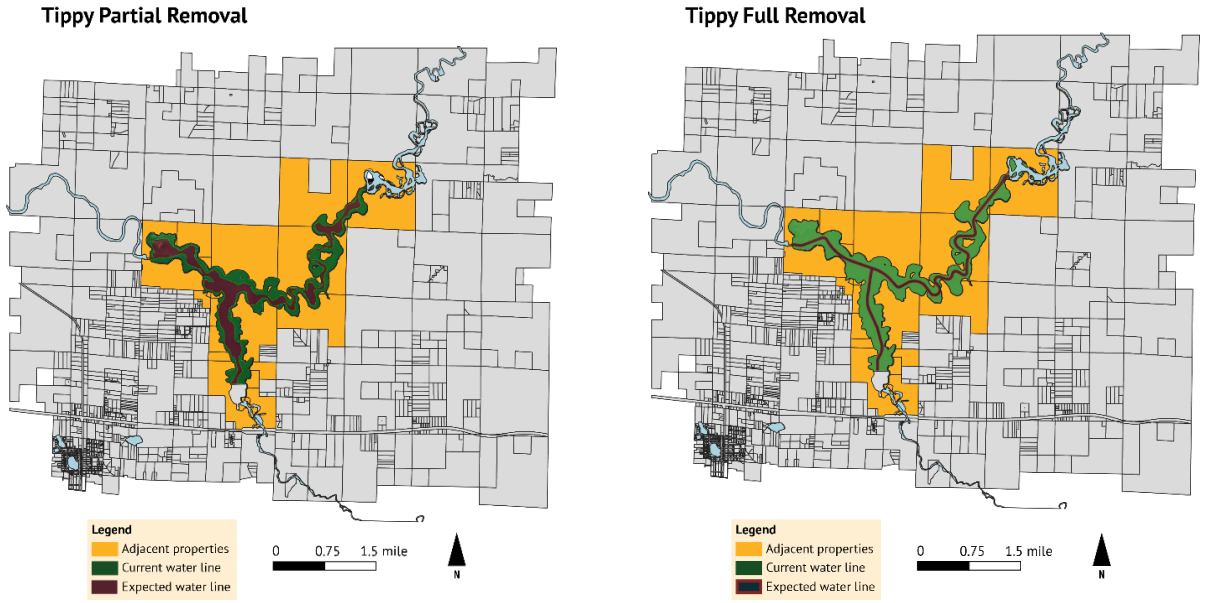
PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Tippy Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background



Along with Hodenpyl Dam, Tippy Dam is situated on the Manistee River. The surrounding township, Dickson, has a population of about 980 individuals. Completed in 1918, Tippy is the second largest hydroelectric dam in Michigan. It is about 82 feet high and 830 feet in length. Tippy Dam Pond measures about 1,330 acres. It has the second largest generating capacity of the 13 Consumers Energy hydroelectric dams, after Hardy Dam.

Environmental Context

While no decision has been made on the Tippy Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Where hydrologic conditions persist over time, wetlands will form. This will likely occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal. Exhibit 4 shows the projected shifts in water line and current impoundment-adjacent parcels.

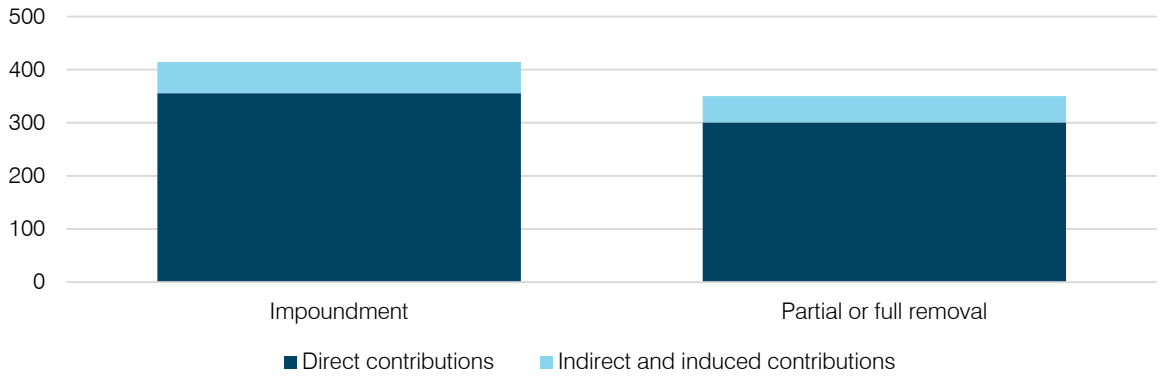
EXHIBIT 4. Partial and Full Removal Parcel Analysis

There is a significant wetland complex and area of undisturbed land directly north and adjacent to the main portion of the Tippy Dam impoundment. This wetland complex extends to the east side of the impoundment's northern lobe.

Partial dam removal is likely to produce significantly different environment effects than a full dam removal. Given the assumptions in the partial removal scenario and the narrow nature of the existing impoundment, it is likely that a partial removal would have a relatively small impact on the habitat surrounding the impoundment. It is likely a large majority of the newly exposed bottomlands would develop as wetlands. There may be some fringe upland development, but it would likely be localized to higher topographic areas and on the southern lobe of the current impoundment.

Under a full removal scenario, it is difficult to predict where wetland and upland formation might occur outside the expected areas, such as inside channel bends and along valley walls with wetland seeps. As with the partial dam-removal scenario, it is likely a large majority of the area on the north side of the impoundment and northern lobe will form wetlands due to the documented wetland. Full dam removal is more likely to produce uplands at the southern lobe outside the immediate influence of the restored river channel. The extent to which this would happen is dependent on the final topographic grading surface.

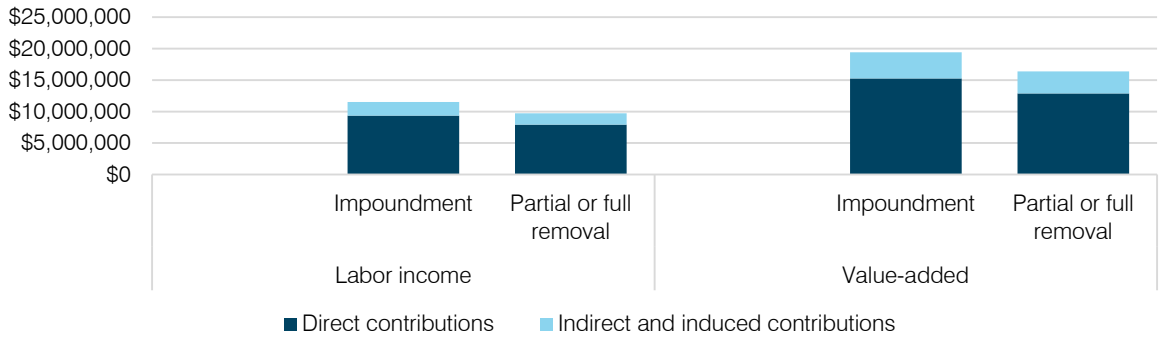
Economic Impact Analysis



To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to

estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis



After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC conducted a single analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Tippy Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 64 fewer jobs in the region and a $3 million reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at Tippy Dam Pond, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).

Property Analysis

PSC compiled assessed and taxable values from the Manistee County Equalization Department and the Wexford County Equalization Department for the tax (calendar) year 2022. In other Consumers dam studies, PSC conducted a property analysis to estimate the impact of partial and full dam removal on impoundment-adjacent properties. Currently, there are fewer than 20 properties around the impoundment not owned by Consumers or the federal government, so PSC did not conduct this type of analysis for this study.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Tippy Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Tippy Dam, which includes:

- A reduction of $3 million in gross regional product and 64 jobs
- A reduction of $862,909 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

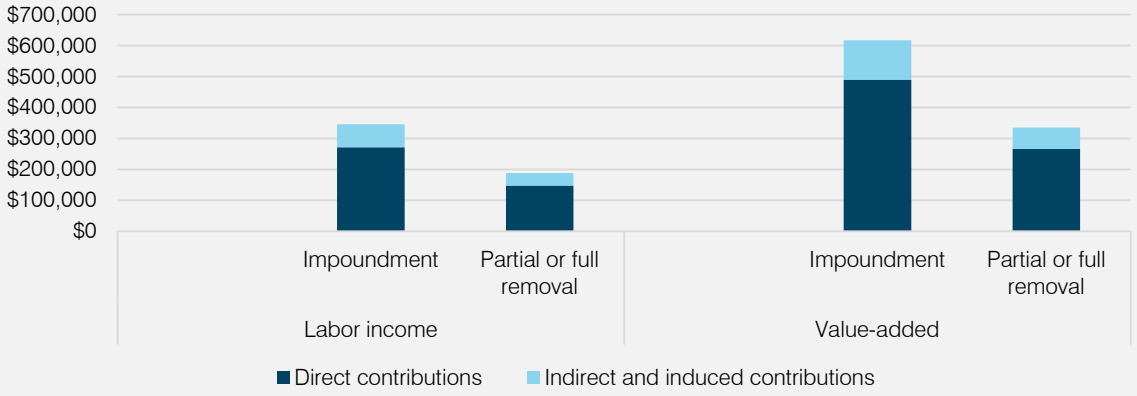
Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to analyze the impacts of partial or full removal of dams on the economies surrounding its 13 river hydroelectric facilities. This work complements PSC's ongoing efforts to assist Consumers in collecting feedback from individuals, organizations, and businesses that would be affected by dam decommissioning. The previous dam studies examined how the dams currently affect the economies of the areas in which they are situated. These economic impact studies project the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section.

Regional Economic and Employment Contributions



IMPLAN, a widely used, reputable economic modeling software, enables PSC to estimate the effects of shifts in expenditures made by recreational users in the area after a hypothetical dam removal. The net change in these expenditures is referred to as direct economic effects, which the IMPLAN model uses to estimate indirect and induced effects, which are secondary expenditures resulting from supply chain purchases, worker spending, and other subsequent expenditures. These measures of new economic activity are reported along with other economic impact measures, including jobs, labor income, and total regional income. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Webber Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 7 fewer jobs in the region and a $281,817 reduction in value-added to the local economy (Exhibits 1 and 2).

EXHIBIT 1. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

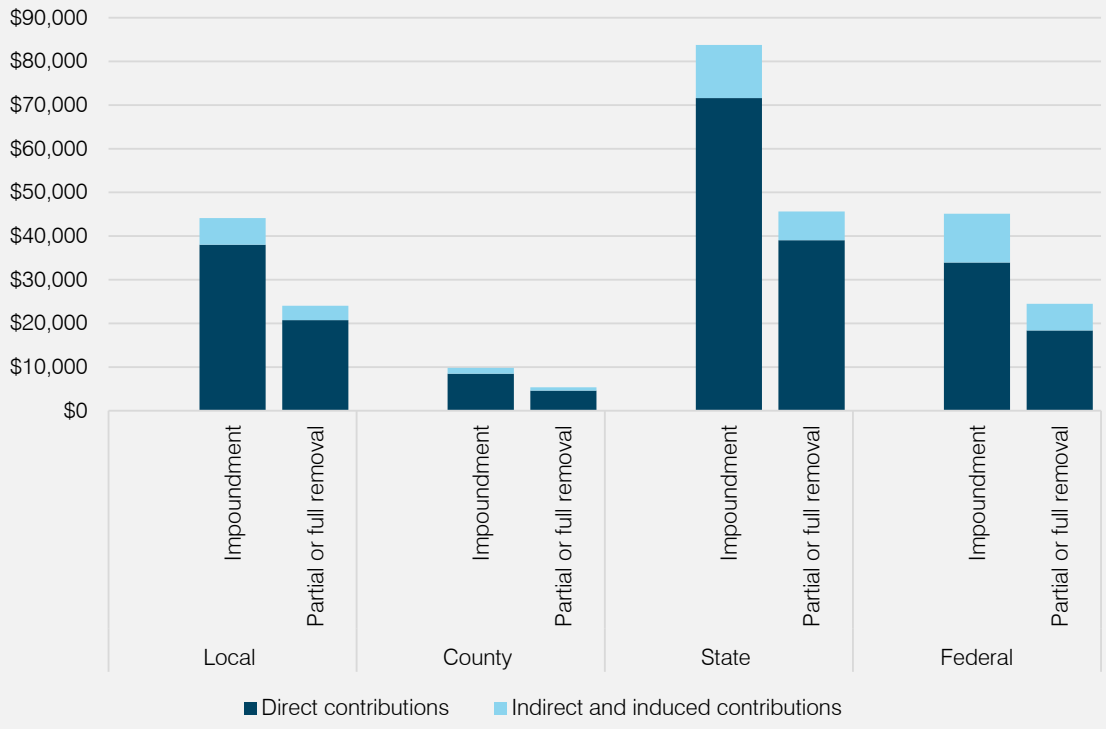


EXHIBIT 2. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $83,332 fewer contributions in total annual tax revenue, with $62,672 of that reduction at the local, county, and state levels (Exhibit 3).

EXHIBIT 3. Tax Impacts— Impoundment and Partial or Full Removal

Source: PSC analysis

Property Value Analysis

To better understand the dam removal impacts on residential property values, PSC analyzed the potential net change in property values and associated annual property tax impact (Exhibit 4).

EXHIBIT 4. Property Analysis Results

	Partial or Full Removal
Number of Properties Analyzed	76
Expected Net Property Value Impacts	
Assessed value	-$550,058
Market value[1]	-$1,100,116
Expected Net Property Tax Revenue Impacts[2]	
Taxable value	-$292,109
Tax revenues	-$9,943
Average millage	34.038

Sources: Iona County Equalization Department; PSC analysis

[1] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[2] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Background

Consumers Energy is developing a long-term strategy for its 13 river hydroelectric facilities. This work is in anticipation of an upcoming relicensing decision, compounded with significant infrastructure upgrades needed to remain in compliance with the Federal Energy Regulatory Commission licensing requirements for each dam. While Consumers is handling much of the work internally, the firm engaged PSC in 2022 to assist with gathering input from the communities where the dams are located as well as more broadly across the state.

In summer and fall 2022, PSC conducted more than 20 meetings with local officials, the public, and key stakeholders. At the meetings, PSC provided the communities with preliminary information on the process for dam removal and collected feedback to assist Consumers in developing its strategy. As part of the feedback collection process, PSC also surveyed more than 3,000 landowners with property abutting Consumers-owned land and created a website to solicit feedback and provide more context on long-term strategy development.

Consumers also engaged PSC to determine how much local economic activity can be attributed to dam-related industries. Previous dam economic contribution studies examined how the dams currently affect the economies of the areas in which they are situated. This economic impact study projects the potential shifts in property values and the local economy within a year of partial or full dam removal under the assumptions outlined in the report's methodology section. To complete this analysis, PSC conducted interviews and collected economic data to complete the assessments. Utilizing IMPLAN, PSC estimated the direct economic effects of spending associated with recreational activity and modeled supply chain purchases, worker spending, and other indirect effects. All the effects were modeled in three categories:

- **Employment:** The number of full- and part-time jobs associated with an industry.
- **Labor income:** The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.
- **Value-added:** The gross regional product, which includes labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes).

For more detailed information on IMPLAN methodology and terminology, see Appendix A.

Approach

This economic *impact* analysis differs from the previously completed economic *contribution* analysis. While both approaches use the same tools to simulate the economic effects of a resource, they differ in some basic assumptions. An economic contribution analysis is a current-state snapshot of the overall market and makes no assumptions about future changes in the underlying economy. An economic impact analysis measures changes in economic activity associated with an event. For this report, partial or full dam removal (considered singly as a full removal) is the event under assessment. A partial removal refers to a scenario in which the river hydroelectric facility is decommissioned yet a structure persists in the river to serve a purpose such as artificially retaining higher water levels or preventing upstream movement of invasive species, such as the sea lamprey.

An economic impact analysis must address several key issues, including the uncertainty of the exact shifts in the environment and recreational activity patterns at each river hydro site, the nonmarket character of many of those changes, and the time horizon for those shifts to occur and then stabilize (Smith 2006). To address uncertainty about how removal would change systems, PSC assumed that the water body will return generally to the river channel as depicted on maps prior to river hydro construction. PSC also focused only on how these changes impact economic behavior and could not place economic value on purely environmental and biological changes that did not directly impact human economic behavior. Finally, to address time-horizon issues, PSC estimated the impact in the first year after dam removal without assumptions regarding future investment, strategic planning, or changes in property ownership. Despite the likelihood of such planning and investment activity in the years between an announcement and completion of partial or full dam removal, it is difficult to accurately estimate its intensity and direction. As a result, PSC did not make any assumptions about its ability to influence economic impacts.

Methodology

PSC conducted a literature review, interviews, data collection and analysis, and utilized IMPLAN to complete the economic impact studies.

Data Collection

Literature Review

PSC conducted a review of applicable research literature and interviewed public and private recreational asset managers to develop assumptions about how the shift from an impoundment to the natural river state would affect recreational activity in the area within the first year of removal. While the research literature indicates that free-flowing rivers can provide greater recreational benefits than impounded rivers over the medium to long term, there is limited research on the immediate impacts, especially without making assumptions about the levels and types of investment and planning during the transition (Loomis 2002; McKean et al. 2005, 2010; Kotchen et al. 2006; Robbins and Lewis 2008).

Stakeholder Interviews

To supplement assumptions derived from the research literature, PSC also conducted dozens of interviews with public officials, recreational asset managers, and other key stakeholders across all 13 sites to discuss the impoundments' economic contributions and re-interviewed a dozen recreational asset managers to explore the potential impacts of partial or full dam removal on various types of facilities (e.g., boat launches, seasonal and nightly campgrounds, roadside parks, etc.). All participants in the dam removal–focused interviews agreed that dam removal would result in a significant short-term reduction of recreational usage, particularly at sites that will lose waterfront access after dam removal. Interviewees also strongly agreed that not all sites and activities would experience the same impacts, which aligned with PSC's research findings. For example, it is likely that camping and day use associated with recreational boating and swimming would be significantly impacted, while hiking and mountain biking are also likely to be impacted, but to a lesser degree. PSC found that facilities directly on the impoundment, which were the focus of the economic contribution and impact analyses, were also the most likely to be impacted than sites further away from the impoundment that serve other recreational opportunities in the area.

Analysis Types

Recreational Analysis

To estimate the impact of partial or full dam removal, PSC combined research findings and local stakeholder feedback to develop a weighted average approach that adjusted the site visitation assumptions in the economic contribution analyses. If a site-specific activity (e.g., fishing, boating, etc.) would be impacted by dam removal, PSC included it in the development of a site-specific weighted average reduction in recreational activity. PSC applied adjustments based on the types of activities currently being offered at each the site that would be impacted by dam removal–related water-level changes.

It is important to note that with proactive planning and enough preparation time, site owners will likely have an opportunity to pivot their offerings to align with the new water level, but in this analysis, PSC has not made assumptions that anticipate sites experiencing increases in other types of recreational activity. For example, a campground that currently offers boat slips for recreational boating could shift to supporting more tubers and paddlers (e.g., canoeists, kayakers, stand-up paddleboarders). That change would mitigate the loss of recreational boaters and provide an opportunity for growth in other areas, but it is challenging at this time to make those assumptions. These visitation adjustments were then applied to the same expenditure profiles used in the economic contribution analysis.

Angler Trips

River systems are complex and predicting how nature and how humans will interface with the changed environment is difficult. In the economic contribution study, PSC estimated the number of anglers at each site and applied an inflation-adjusted, angler-specific expenditure profile to derive estimates of the transactions that could be attributed to current angler activity and associated economic contributions. This was viewed as the best approach from which to derive comprehensive estimates of the economic value of recreational fishing along the Consumers Energy river hydro facilities. An economic impact assessment must go one step further to conjecture how angler-related transactions will change following a major event (e.g. partial or full dam removal). This effort is much more challenging to derive, as it requires inferring how partial or full dam removal will affect angler activity. Many factors will influence angler responses, including how the fish populations will change and the fishing preferences of those who currently fish the area as well as who are the potential anglers that would be drawn to the area.

Unfortunately, recent academic research shows that generalizing how fish populations will adapt to dam removals is difficult and results in questionable conjectures at best, as the large number of variables makes both short- and long-term projections inexact (Hansen et al. 2023). Even the most data-limited approaches require significant amounts of data related to growth, feeding and prey preference, reproduction, and biomass data for each individual species in combination with a variety of system-wide parameters (Bellmore et al. 2017). They also require significant use of assumptions that may bias findings depending on the validity of the assumptions applied.

In addition to these challenges, it is especially difficult to predict the short-term impacts of shifts in fish populations, how those impacts will affect the fishery, and how that will affect the number of anglers and types of angling at a former-impoundment water body. Due to the narrow prediction window of this analysis, capital investment and shifts in recreational access are not assumed to take place, further complicating the estimation of changes in angler activity following partial or full dam removal.

PSC's approach to estimating the economic impacts is predicated on applying similar methods across all 13 hydro facilities, which further constrains the ability to collect data and develop models with sufficient predictive power to inform on the expected changes in angler opportunities. That is, the objective to be consistent across the 13 study sites further complicates the ability to apply a universal approach across these sites in a methodologically consistent and rigorous manner.

Furthermore, most studies note that these shifts are impacted by the time frame for species recovery and environmental shifts and rely on analyzing systems outside Michigan, which is another complicating factor in attempting to analyze these shifts in this analysis. While the determination was made not to estimate the economic impacts of changes in angler activity in the short-term response to partial or full dam removal, PSC includes a discussion of potential long-term benefits in the report.

Property Analysis

Projecting changes in property values is a major component in calculating the economic impact of partially or fully removing the Webber Dam. There are two related implications for the local economy. First, changes in the value of one's property affect household wealth. According to the Federal Reserve Board, the value of housing makes up approximately one-half of household wealth on average (Iacoviello 2011; Bostic et al. 2009). Accordingly, unexpected changes in property values can have significant implications for one's financial security. As households spend out of both income and wealth, a change in wealth has economic implications and may result in changes in household expenditures. While the potential for changes in household expenditures exists in what economists call the wealth effects on consumption. Wealth effects on consumption are relatively small as households seek to balance wealth accumulation and lifetime expenditures. Accordingly, this analysis sets out to document the changes in wealth as measured in the expected changes in residential housing values but makes no assumptions on changes in household purchasing behavior because of such wealth effects. Second, public revenues for local government units largely rely on property taxes levied based on the value of the community's underlying properties. Accordingly, a change in property values will have direct implications for government revenues necessary to support public services like the emergency services, local schools, parks, and others. Therefore, in addition to projecting changes in regional wealth, the property analysis will also project expected impacts on public revenues through residential property taxation.

Webber Dam

To provide valuable context for the economic impact analysis results, this section includes a high-level overview of the dam, as well as some general and site-specific information about the short-term environmental context in the event of partial or full dam removal under the study's assumptions.

Background

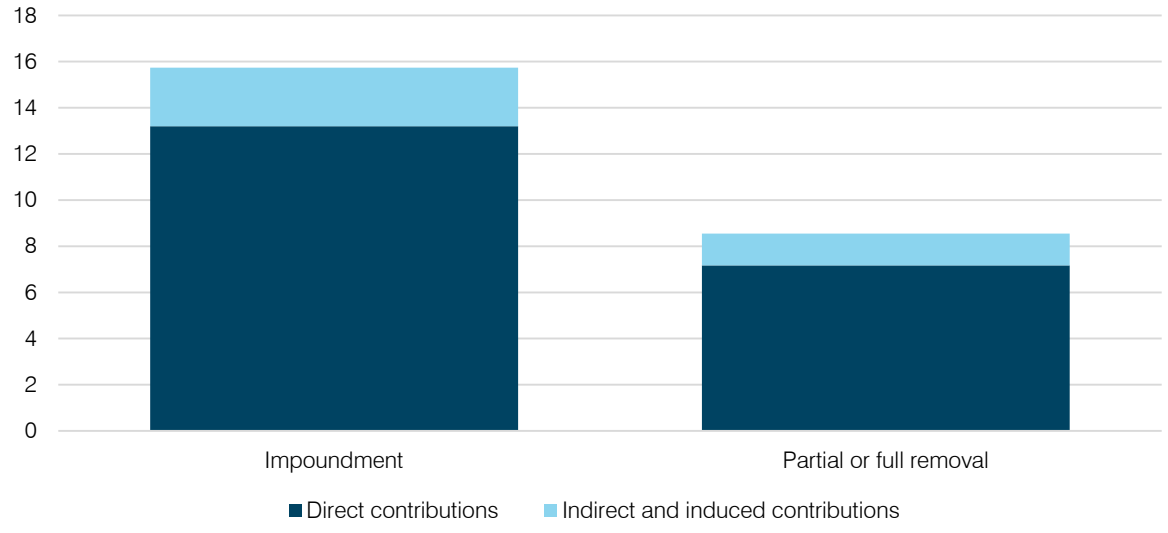
Webber Dam is the tallest dam on the Grand River and the only Consumers-operated dam on the river. Located about six miles north of Portland in Ionia County, Webber Dam was completed in 1907. The dam is about 30 feet high and 1,200 feet long, with a capacity of 3.25 megawatts. The average output is 1.3 megawatts per day, the smallest of Consumers 13 hydroelectric dams. The 660-acre impoundment is not officially named.

Environmental Context

While no decision has been made on the Webber Dam's future, it is important to understand the short-term environmental context. With dam impoundment projects involving significant dewatering, there is a length of time where the exposed bottomlands (previously impounded sediments) need to dry out. This process usually completes itself during the construction phase of a project as the impoundment is lowered. Currently, there is no indication that the sediments within the 13 river hydros have an abnormal propensity to hold moisture. For the purposes of high-level environmental assessments, it is assumed that the impounded sediments have dried to the extent possible within the construction time frame, typically within the first six to nine months of the project. For all 13 impoundments, the first year after construction will largely consist of the progression of raw, recently disturbed soils to increased vegetation growth.

Where hydrologic conditions persist over time, wetlands will form. This will likely occur near and along tributaries, following the tributary's path to the point where it joins the mainstem of the restored channel, near groundwater seeps occurring along valley walls or high groundwater tables, and in the floodplain areas of the restored main channel. Generally, former dam impoundments will form a mix of wetland and upland ecosystems. The exact locations of these are largely determined by the site-specific hydrologic conditions of the soils and final topographic surface after partial or full dam removal.

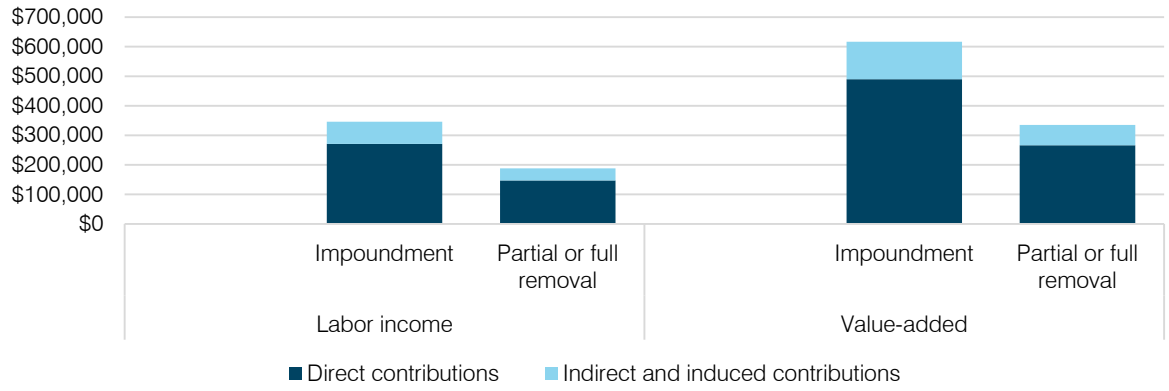
The historic Webber Dam impoundment survey lacks detail related to habitat types of the former bottomland. Based on the MNFI wetland viewer and the restored river channel alignment, some wetlands will likely form on the inside bends of the restored channel. There are also two areas where wetlands could potentially reach from the restored channel to the eastern extent of the current impoundment. The MNFI wetland viewer identified wetlands or wetland characteristics in these two areas, signifying the likelihood for wetland formation along the impoundment edge propagating toward the restored river channel. Depending on the final topographic surface of the remainder of the impoundment, upland land type could be expected to form in the rest of the impoundment.



Economic Impact Analysis

To assess existing recreation-related activity for the economic contribution study, PSC spoke with local government officials, recreational asset managers, and other community stakeholders to identify existing reports and collect data on the number and types of visitors of the recreational facilities surrounding the pond. Where data were not available from local sources, PSC used a cell phone data mapping service to estimate annual users. PSC then applied nationally recognized, inflation-adjusted recreation expenditure profiles to these trip counts to create the inputs for the IMPLAN analysis.

Recreational Analysis



After applying the approach outlined in the methodology section of this report, adjusted site visitation estimates were applied to the same expenditure profiles used for the economic contribution analysis. The IMPLAN results under these assumptions were then compared to the previous economic contribution results to determine the economic impact of dam removal. After reviewing maps of the area, PSC conducted a single analysis of the full removal scenario because there was not a meaningful difference between the full and partial removal scenarios. Using IMPLAN and data collected from local and state sources, this analysis estimates the short-term economic impact of the full removal of the Webber Dam. The short-term estimated effects documented in this report are intended to reflect the economic impacts during the first year following dam removal. The extent to which they persist over time will depend on how quickly the local economy changes to accommodate the new economic environment. PSC estimates that in the first year after dam removal, recreational activity in the area surrounding the impoundment would result in 7 fewer jobs in the region and a $281,817 reduction in value-added to the local economy (Exhibits 5 and 6).

EXHIBIT 5. Employment Results—Impoundment and Partial or Full Removal

Source: PSC analysis

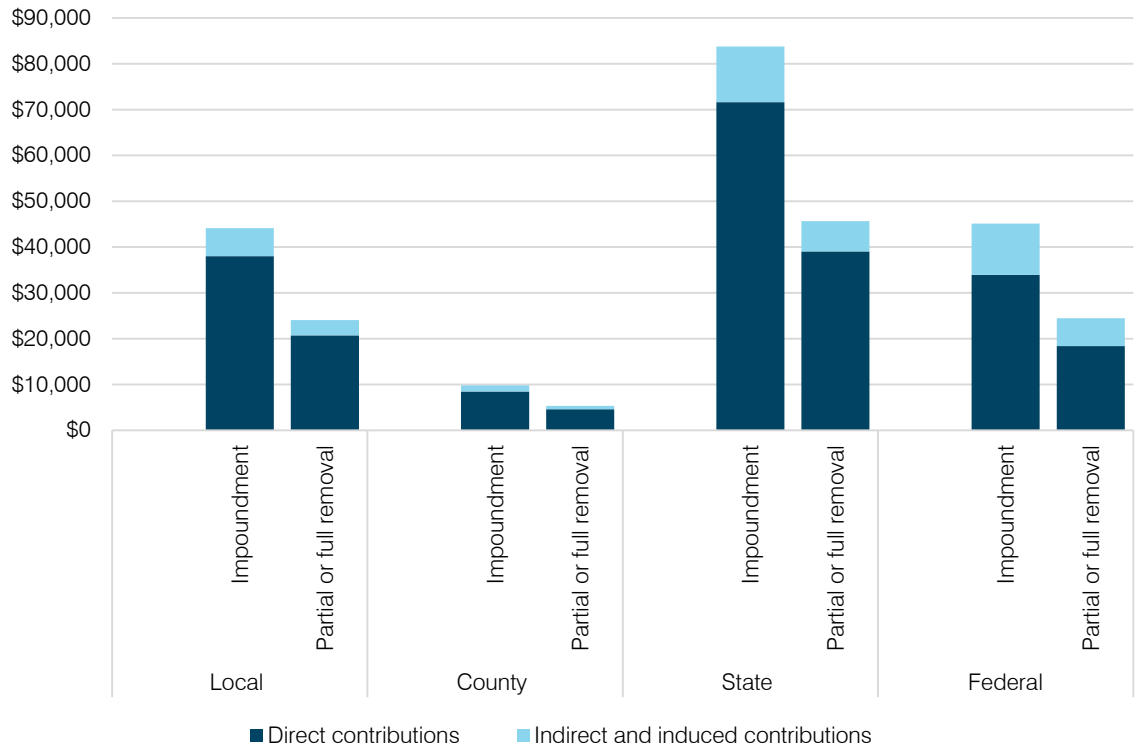


EXHIBIT 6. Labor Income and Value-added Impacts—Impoundment and Partial or Full Removal

Source: PSC analysis

These estimated shifts in recreational activity will also result in $83,332 fewer contributions in total annual tax revenue, with $62,672 of that reduction at the local, county, and state levels (Exhibit 3).

Discussion

Short- versus Long-term Shifts in Economic Activity Following Partial or Full Dam Removal

Though this analysis focuses on short-term reductions in economic activity, studies show recreational activity and spending can recover and even outpace impoundment spending in the long term (Loomis 2002). Capital investments and other supports to help recreational assets shift to serving river-based activities could mitigate losses and maximize opportunity. Also, some studies indicate that a return to river creates opportunities for more access points, which can increase the economic contributions of river-based recreational activity (Bi, Borisova, and Hodges 2019).

At a regional or state level, the jobs and spending measured in this analysis are unlikely to be lost, given that those partial to the activities most impacted by dam removal (e.g., pontoon boaters, lakeside camping, water skiers, etc.) are likely to find another place in the state to do these activities (Bi, Borisova, and Hodges 2019). However, at the local level, unless these activities are conducted elsewhere in the immediate area—which is not assumed in this analysis—the reduction in visitor trips and spending will have economic impacts.

Partial and Full Removal Considerations

For all economic impact reports, PSC considered both full and partial removal scenarios, but in some cases, including at the unnamed Webber Dam impoundment, it appears that the shifts in recreational activity associated with the water levels under a partial removal would not produce significantly different outcomes. While it is possible, if unlikely, that the economic impacts of a partial removal would be different from those following a full removal, those differences would not be measurable when making the assumptions and developing the approach necessary to model these shifts. For this reason, PSC did not conduct a separate analysis of what the impacts would be under a partial removal scenario.

Other Potential Impacts Not Measured

Angler Activity

As noted in the methodology section of the report, PSC did not estimate the changes partial or full dam removal will have on angler activity and the associated economic effects of those activities. However, there is sufficient research to suggest that dam removals generate significantly positive benefits to anglers and restore fisheries to their normal habitat. A recent long-term effect study following the removal of the Edwards Dam along the Kennebec River, showed greater overall angler satisfaction with fishing endeavors along the Kennebec (Robbins and Lewis 2008). Both willingness to pay to fish and actual fishing-related expenditures increased after dam removal. While McKean et al. (2010) support the finding that anglers' willingness to pay increases and their actual expenditures for fishing increase after dam removal, they found that the expenditure effects may be partially mitigated by lower visitor counts. Regardless, the net effect observed was a net increase in regional economic growth around angler activities. These long-term studies observe effects well after a new normal life cycle exists in the river system and that transition can take years.

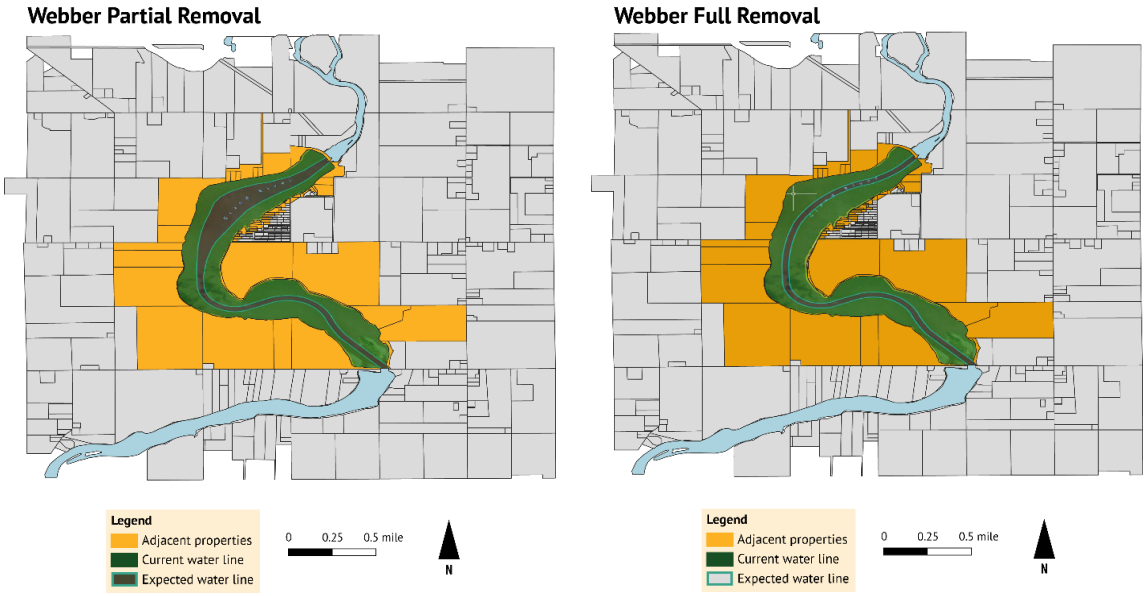
Other mitigating circumstances should also be considered. For example, not all anglers prefer river fishing, as many seek deeper water fishing activities via boat rather than bank and/or fly fishing in cold spring waters. That is, the net effect on fishing activity may have as much to do with the preferences of recreational anglers as it does on the river ecosystem. Supply and demand dynamics are also important to consider, as changes that increase the costs of fishing activities may result in a decrease in visitor fishing

trips (Hwang et al. 2020). If lowermost dams are removed, a seasonal barrier may be needed to prevent movement of the invasive sea lamprey upstream. Such barriers could also hamper natural fisheries restoration, which may or may not have long-term implications on angler activities along the river.

Ecosystem Services

Nature provides vital contributions to economic and social well-being that are often not traded in markets or fully considered in land use, business, and other economic decisions. Ecosystem services are direct and indirect benefits to people from nature and are often not priced because they are not traded, and often are difficult to observe. In the case of a river, these contributions include water cycling and purification; mitigating or propagating flood events; the support of habitat for diverse populations of birds, fish, and mammals; carbon sequestration; and cultural and aesthetic benefits, to name a few. Consider one known ecosystem disturbance by dams. Many of Michigan's fish populations prefer coldwater environments that are generally supported by spring water. Michigan's low water table produces multitudes of springs–groundwater that flows naturally to the water surface due to features of the water table and surface topography. Within a water system, impoundments result in warming river water, even downstream from the dam. Cold spring water that does intermingle with lake water gets diluted into the warmer water system to the detriment of natural habitat for cold water fish like salmon, trout and sculpins.

While research and literature on ecosystem services abound, PSC has not estimated the impacts of the presence or absence of the river hydros on ecosystem services because the scope of measurement is beyond the existing scope of work. Research articles highlight the challenge of quantifying the values of ecosystems of nonmarket goods and services, including recreational activity (de Groot et al. 2012; Steinman et al. 2017). Also, while decisions that affect these services are often made at the local level, "issues such as fisheries and water levels require sustainable management at the basin scale, where coordination, valuation, and assessment may face greater logistical challenges" (de Groot et al. 2012).



Property Value Analysis

The Webber Dam impoundment has 76 adjacent residential lots that likely benefit from access to the current impoundment. To what extent residential property values would be affected by a partial or full dam removal depends on a property's proximity to the resulting water's edge. This is because relative to a full dam removal, a partial removal retains a small impoundment that extends the water's edge to more properties. Exhibit 8 shows two maps of property plats around the Webber Dam impoundment, one depicting the extent of the expected water line under a partial dam removal and one showing the same under a full dam removal. The expected extant of the water body after dam modification is shown by the green and blue insert. All other points along the river system are assumed to be invariant between the two scenarios and from the current relationship with the water system.

PSC determined the potential net change in property values and associated annual property tax impact of the proposed dam modifications. These are highlighted in Exhibit 9. Accordingly, the relatively smaller impoundment expected with a partial dam removal will provide waterfront access to more properties than under a full removal. Because more lots will have greater water proximity than with full removal, the partial-removal scenario would be expected to have a lesser overall negative effect on overall residential property values and annual residential property tax revenues. Because there are residential properties differentially impacted by the partial and full dam removal scenarios, this assessment anticipates that the partial and full dam removal scenarios will have measurable differences in effects. As indicated in Exhibit

9, 76 impoundment-adjacent properties will experience a cumulative reduction in market values of around $973,032 under a partial dam removal and $1,100,116 under a full dam removal. Similarly, annual residential property tax revenues are expected to decrease by about $8,794 and $9,943 under the partial and full removal scenarios, respectively.

EXHIBIT 8. Partial and Full Removal Parcel Analysis

The results of PSC analysis on the potential net change in property values and associated annual property tax impact are highlighted in Exhibit 9.

EXHIBIT 9. Property Analysis Results

	Partial or Full Removal
Number of Properties Analyzed	76
Expected Net Property Value Impacts	
Assessed value	-$550,058
Market value[3]	-$1,100,116
Expected Net Property Tax Revenue Impacts[4]	
Taxable value	-$292,109
Tax revenues	-$9,943
Average millage	34.038

Sources: Iona County Equalization Department; PSC analysis

[3] Estimated wealth effects are the change in the expected market value, which is calculated as two times the assessed values.

[4] Taxable value, along with the effective millage rate, determines the expected changes in annual property tax revenues.

Conclusion

Building on previous community engagement and economic contribution work conducted by PSC, this report is intended to provide insights on the potential economic and property impacts of partial or full removal of the Webber Dam. Given the levels of uncertainty present with any potential removal project, PSC made several key assumptions, which are discussed in more detail within the report's methodology section. These include analyzing the potential impacts in the first year after partial or full dam removal and not make any assumptions about new recreational activities or facilities that could increase visitation following regional planning and investment efforts.

Under this set of assumptions, local recreational assets are likely to be significantly impacted in a partial or full dam removal scenario. Shifts in visitation activity will affect employment opportunities, tax revenue, and economic contributions to the broader economy. PSC research suggests that over the long term, recreational activity is likely to return.

This report includes a full breakdown of the potential economic impacts of the partial or full removal of the Webber Dam, which includes:

- A reduction of $281,817 in gross regional product and 7 jobs
- A reduction of $83,332 in local, county, state, and federal taxes through direct, indirect, and induced tax effects from recreational spending

The partial or full removal of the dam will also impact adjacent property values, contributing:

- A reduction of $1.1 million in market value to adjacent properties
- A reduction in $9,943 in local and state property tax revenue due to the decreased market value

Appendix A: Methodology

IMPLAN Modeling

To analyze the amount of money visitors and residents spend on recreation related to the dam impoundments, Public Sector Consultants used IMpact for PLANning (IMPLAN), an input-output model to estimate economic impacts and contributions. It is a staple for regional economic analysts.

Economic Impact and Contribution Analyses

There are two major frameworks for input-output simulations. The first is an economic impact analysis, which examines the effect of something that affects the economy—like changes in wages or jobs—in a specific area. In this case, it is the dam impoundment and the recreational activities and expenditures associated with it. Because an economic impact analysis provides a model of what the economy is like with the economic feature being examined—in this case, the dam impoundment—a full accounting of what the economy would be like without the feature is required in modeling the outcomes.

The second framework is called an economic contribution analysis. This framework does not consider the possible absence of an economic feature. It only models the value of economic activity that can trace its source back to the existence of the economic feature being modeled.

IMPLAN Terminology and Methodology

Input-output models trace transactions among and between different economic sectors (like households, businesses, and governments) over the course of a year. Tracing these transactions offers a clearer picture of how a change in economic activity in one part of the economy creates changes in other parts of the economy. When a business sells from inventory, it takes a portion of those earnings to pay for other goods and services (for example, to restock its inventory). Some of the wages companies pay to employees will go to local retailers and service providers, continuing the ripple effect throughout the economy. Because of all of these additional transactions, the overall economic effect is greater than the value of all the different direct revenue streams (employer to employee, consumer to business, business to business, etc.), which is called the multiplier effect. The existence of multiplier effects in regional and national economies is well documented in economics literature (Coughlin and Mandelbaum 1991).

Direct Effects

The standard approach to modeling economic impacts with input-output models is to begin by establishing the value of transactions that represent direct expenditures related to the dam and impoundment. For the purposes of this study, these are expenditures by individuals utilizing impoundment, feeder river system, and other adjacent recreational facilities. The direct effects of this spending are organized into various commodity categories. Each commodity type, such as grocery retailing, gasoline, and restaurant meals, have unique economic profiles in the local economy. For example, purchases made at a local grocery store create a different set of secondary transactions than purchases made in other industries.

While recreational expenditures make up the direct effects, they are largely derived from the number of recreational users at facilities around the impoundment. As discussed above, the analysis assumes that these users will spend money in a particular pattern while visiting recreational assets in and around the

dam impoundment. The expenditure profile used for this analysis is an inflation-adjusted version of the one adopted by the United States Department of Agriculture and United States Forest Service (USDA/USFS) (White 2017). Expenditures by recreational users are measured on a per-party basis. To account for the different spending patterns of impound visitor types, party counts were broken out into distinct categories.

Indirect and Induced Effects

These direct effects are then used to estimate the secondary transactions that happen because of the direct effects. The first set of secondary transactions is the indirect effects, which are transactions between business sectors. Indirect effects are the intermediate purchases of goods from one business by another (such as restocking). A business's operational costs—like electricity, rent, and business services—are also indirect effects. Indirect effects ripple throughout the economy as businesses purchase goods and services from other businesses. These transactions cascade throughout the region, reduced only by the extent that inputs are purchased from suppliers outside the region. The second set of secondary transactions are called induced effects. Induced effects measure the value of new transactions by households, governments, and other institutions in response to higher labor income, taxes, and profits. These household and institutional expenditures from earnings generate new rounds of business-to-business transactions and associated payments to institutions. These expenditures continue throughout the regional economy, hampered only by the extent to which purchases are made for goods, services, and payments to institutions outside the local economy. The direct, indirect, and induced effects are summed together to calculate the total economic effects.

Contribution estimates start with the estimated total value of purchases by category. Standard input-output models examine the economy through the flow of transactions. However, figures for employment, labor income, and total regional income, which are also known as contributions to gross state product, are determined with fixed ratios to the value of sales transactions. For instance, if Industry X employs one employee for every $1 million in sales, then an increase in sales by $10 million translates into an increase in employment by ten workers. Similar fixed ratios for labor income and gross state product apply. The IMPLAN model provides 544 expenditure categories, and 11 household types by income group.

Property Value Analysis

Estimating the expected impact of removing or reducing the impoundment on residential property values relied on a long literature of academic studies on this topic. Most studies underlying this literature apply some form of Hedonic regression analysis to estimate the value of proximity to the water feature. For this analysis, water features entail lake/impoundments and rivers, where the contrasts in value contributions across the two provide a basis for understanding how the values of properties that are currently impoundment-adjacent will change once becoming river/stream adjacent.

Hedonic analysis assumes that the water feature, whether an impoundment/lake or stream/river, has some amenity value to adjacent homeowners that will be reflected in the property values. If proximity to the water feature is deemed desirable, those properties adjacent to the water will tend to command a higher market value than identical properties (comparable properties) that are not proximal to the feature. Accordingly, Hedonic analysis generates valuations of comparable properties statistically. These statistically derived baseline valuations can be compared to properties adjacent to water features for estimating the average or expected impact of the water feature to comparable properties.

This economic impact assessment of the effect of removing the impoundment on property values will use a benefit transfer method (Johnston and Rosenberger 2010). Relative to a site-specific specific study, which would use location-specific property data for developing a model that estimates the water feature's (whether impoundment or lake) contribution to property values, a benefit transfer approach applies a model of the relationship from another study site and applies that model to the site in question, usually called the policy site.

The benefits of this type of approach are that the underlying model representing the value contributions are often much more robust than can be attained from a site-specific study. Many reasons exist. First, inclusive studies of property value impacts of natural amenities are expensive to undertake and require significant time investment to collect the relevant property data. This project's budget and timeline over thirteen impoundments preclude such inclusive, site-specific studies. Second, the study area data is not uniformly sufficient for undertaking comprehensive hedonic analyses. Candidate study sites are those with significant counts and varieties of both effected and baseline housing units by which property values can be compared. The sites should also have comprehensive measures across each housing unit, like year built, square footage, age of last updates/mechanicals, number of rooms and baths, lot size, and other measures common in describing residential properties. That is, the valuations from published study sites are derived from ideal conditions that often do not exist in sites of interest and can therefore provide generalizable estimates of the relationship between residential property values and proximity to water features. However, benefit transfer applications have a shortcoming in that its application may bias the predicted contribution if the study site characteristics are sufficiently unmatched by the policy site.

In estimating effects, it is important to be able to apply unit-free measures, like percent change in values from baselines rather than absolute dollar values. Such unit-free measures allow for transference of values when value scales differ between the study and the policy sites. For example, a study that establishes that proximity to a river feature elevates property values by $8,000 on average is more significant if the baseline property values are $100,000 than if they are $200,000. Alternatively, a finding that shows proximity to a river elevates property valuations by 8 percent is fully scalable and applicable if the baseline property values are $100,000 or $200,000.

Accordingly, an inclusive review of existing hedonic studies of the effects of water features on residential property values was referenced to identify relevant studies for consideration in the benefit transfer estimates. Sarah Nicholls and John Crompton's 2018 article in the academic journal *Lakes & Reservoirs* is a comprehensive review of existing studies on the effects of lakes, lake water drawdowns and rivers on property values. The review shows a great deal of consistency in generalized findings, that adjacency to lakes or impoundments tends to be associated with increased market values of residential properties, even when controlling for other property amenities, like square footage, number of rooms, lot size, etc. Multiple studies suggest that adjacency to any water feature tends to be associated with higher residential property values, but that the effect is larger for lake adjacency than for that of rivers. Studies comparing residential property values before and after a permanent impoundment drawdown reinforce the valuation effect differences between lakes/impoundments and rivers/streams. However, the effect decreases with distance between properties and the water feature. The model should consider these three stylized findings.

Key papers that influenced the adopted model of residential property effects include studies that show a clear positive effect of water adjacency and views to water features, as well as a study that found no effect of water adjacency on property values. Additionally, studies used were geographically diverse. Boodt

(1978) compared property values surrounding five Oregon lakes against baselines finding both significant and insignificant effects, but an overall average positive effect of a 15 percent boost in residential property values for those lots adjacent to lakes or reservoirs. A study of Northern California properties (Kruse and Ahmann 2009) generated significantly more prolific estimates of the effects of adjacency to water bodies, showing that adjacency boosted property values by over 100 percent relative to comparable baseline properties. This study also shows the effect of unobstructed scenic views of water bodies alone contributes about 28 percent boost in property values. Varying geography, one study (Muller 2009) controlled for the presence or absence of reservoir management with proximity and views of reservoirs in Indiana and Connecticut, determining that proximity to or views of water bodies is not sufficient to assure a positive effect of lake proximity to residential lot values. Once the valuation of water views has been incorporated into property value estimates, the effect of adjacency on property values moderates (Espey et al. 2007; Sander and Polasky 2009), suggesting that the visual vista is a key component of the value homebuyers place on lake adjacency. For this assessment, the expected premium associated with reservoir adjacency is set to 37 percent, which is on the lower spectrum of estimates. The lower, more conservative estimate is applied because the loss of lake adjacency will be replaced by adjacency to the restored river.

A few studies in the review (Conner 1973; Sander and Polasky 2009, Tapsuwan 2015) compared the valuation boost to residential properties between adjacency to lakes and rivers, noting that the estimated effect of river adjacency is slightly less than one-half that of a reservoir. The general rule under the modeling scenarios is that with a full dam removal, all lake adjacent properties will lose the lake premium. After dam removal, those properties that remain adjacent to the river will benefit from the lesser river premium that will partially offset the lost lake adjacency premium.

Finally, several studies (Brown and Pollakowski 1977; Doss and Taff 1996; Mahan, Polasky et al. 2000; Sander, Polasky et al. 2010; Stetler, Venn et al. 2010) observed that distance from the water line tends to be associated with lower water adjacency premiums. Though the estimates varied by study, the findings tended toward centering on a.045 percent decrease in the overall adjacent property value per ten yards of distance from the water's edge.

Accordingly, the following model is applied to both assessed and taxable values to gauge the expected net effect of partial and full removal of the respective dam.

$$((PropValue_{n,s}) / (1 + .3696 * front_s)) \ * \ (1 + .1512 * river_s) \ * \ (1 - .00038 * \ yards_s)$$

The variable PropValue takes the value of n = {Assessed Value or Taxable Value} for scenario s = {Full Removal or Partial Removal}, where the scenario dictates whether water frontage is lost ($front = 1$), whether the property will retain adjacency to the river ($river = 1$) and the distance in yards the property's edge from the water front ($yards$). Because the same model is applied to taxable and assessed value, the model implicitly assumes that taxable, assessed, and market values move in proportion to the others.

Executive Summary

Consumers Energy engaged Public Sector Consultants (PSC) to meaningfully involve community representatives and interested parties in the discussions about the company's river hydroelectric plants (river hydros) for the third year since announcing its long-term hydro strategy. PSC lead development of seven community stakeholder groups tasked with generating their ideas of community prosperity under three different scenarios for the river hydros—whether the river hydro is relicensed, sold, or decommissioned—and in so doing, provide counsel to the company. Guided by facilitators, prosperity group members provided their perspectives and honed their recommendations for the different scenarios in multiple meetings convened between April and November 2024.

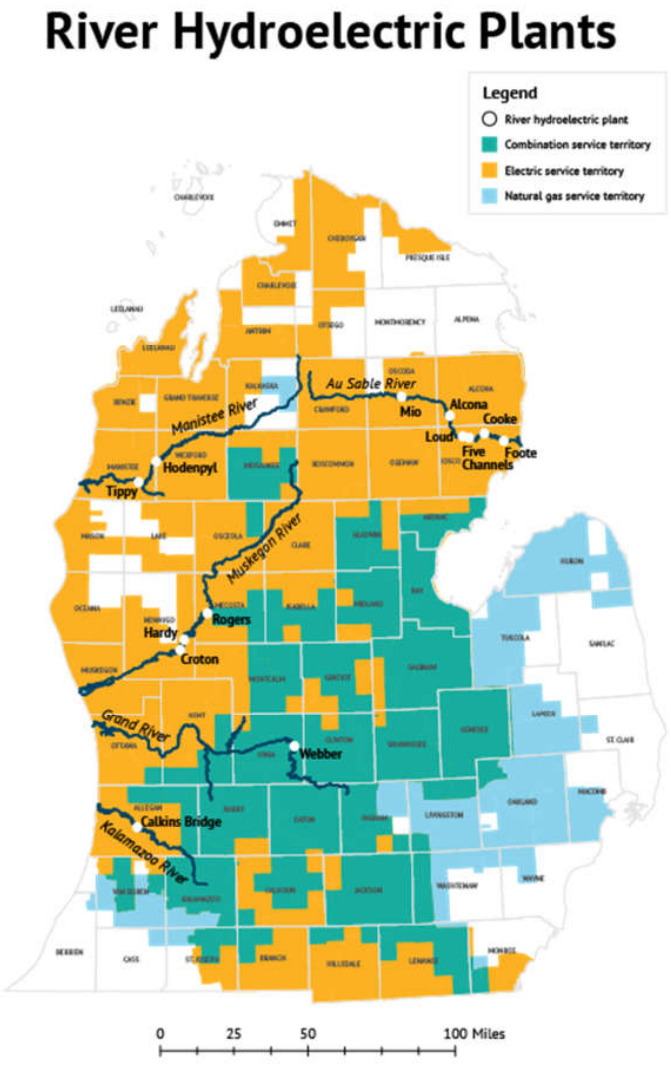
The framing questions used to shape the prosperity groups' feedback for each of the three possible scenarios is listed below.

1. **Relicensing—**How would the prosperity group like Consumers Energy to build a community benefits package in the next relicensing period?
2. **Sale—**What would the prosperity group like Consumers Energy to ask for on behalf of the community should a sale occur?
3. **Decommissioning—**What are the key investments the prosperity group would like Consumers Energy to make to support the long-term prosperity of the community post-impoundment?

Through various group and individual exercises, facilitated discussions, and presentations on topics such as rural economic development, dam removal and river restoration, and fisheries and wildlife, group members identified priorities for each scenario along with key actions and launch steps. These priorities are being shared with Consumers Energy, which will take them under advisement as the company considers its long-term strategy for the river hydro fleet.

Each prosperity group and river hydro are unique, yet several themes emerged across them as community prosperity summaries were developed.

- The health of local fisheries on all five rivers (Au Sable, Grand, Kalamazoo, Manistee, and Muskegon) is a priority for environmental and economic reasons.
- In most river hydro communities, the river hydros play an outsized role in local economies as significant land areas are federally or state owned and/or in agricultural use.
- Outdoor recreation that attracts residents and visitors is a major source of revenue for rural economies where the river hydros are located, which is an asset that could also lead to overdependence on a single sector.
- Whether Consumers Energy or a new entity owns the river hydros, group members voiced concern about viable maintenance of the facilities if FERC granted another license, given changing energy markets and impacts from climate change.
- Groups also question the ability of a new owner to safely maintain the river hydros.
- In the event of decommissioning and removal, creating a land management strategy was consistently identified as a means for tackling issues such as use and ownership of previously submerged land, recreation opportunities, and sediment management.
- Groups stated the need for better promotion and marketing of these regions for tourism and business attraction.



- Groups also identified strategic investment in outdoor recreation and access to land and water opportunities.

The river hydro communities and other key stakeholders are engaged and ready for the next step, whatever it may be—provided Consumers Energy keeps them engaged and current in a timely, transparent process.

Introduction

For more than a century, Consumers Energy has owned and operated river hydroelectric plants to generate electricity. Today, only 13 river hydros remain in their fleet, and most of them have Federal Energy Regulatory Commission (FERC) operating licenses that expire within the next decade (Exhibit 1). The company, as the owner and licensee, must file with the FERC a notice of intent to apply for a new license at least five years before the existing license expires. So, in 2022, Consumers Energy began a detailed review of its river hydro operations to understand the financial, societal, and environmental impact of the three options available to them: pursue relicensing of the river hydros; decommission and remove the river hydros; or to sell the river hydros and transfer the licenses to a new buyer.

EXHIBIT 1. Map of River Hydro Plants with Rivers, Key Place Names, and Consumers Energy Service Areas

Consumers Energy and PSC hosted public meetings in each of the 13 river hydro communities in 2022 and again in 2023 to share information with residents about Consumers Energy's hydro fleet, the FERC license process and timelines, answer questions, and receive concerns. Materials produced as part of that outreach are available for download at The Future of Hydroelectric in Michigan website.

In 2024, Consumers Energy and PSC supported the formation of prosperity groups for each river hydro community composed of diverse stakeholders and led by community-based conveners. Regardless of whether Consumers Energy decides to exit from or relicense their river hydro facilities, the company recognizes the economic contribution the dams and impoundments have created for these communities, and wants to understanding how it can be a partner in supporting community prosperity and demonstrating Consumers' long-term commitment to the communities. In creating groups for collaborative thought and action, Consumers seeks to build lasting relationships for local prosperity during and after it makes its decisions.

Community Engagement Calendar 2022–2024

Consumers Energy has consistently engaged river hydro–adjacent communities for the past three years, providing venues for discussion and information gathering. The dates and locations for public meetings and prosperity group meetings in the communities since 2022 are presented in Exhibit 2, arranged by river and river hydro. Two virtual meetings were offered in 2023, as well. Meeting materials are available for download on Consumers Energy's website.

Virtual Meetings		Sept. 12, Nov. 16	

Prosperity Groups

In 2024, Consumers Energy and PSC shifted focus from annual community meetings to engaging with a smaller, representative group of people and organizations on a quarterly basis for each of the river hydros. These groups were tasked with envisioning community prosperity with or without a river hydro (or dam) operated by Consumers Energy as part of the utility's long-term commitment to the communities. To accomplish this, local stakeholder groups, called prosperity groups, met throughout the year under the guidance and leadership of community-based conveners and PSC. The groups provided collaborative input and broad perspectives as they identified issues to be addressed in case of a dam relicensing, ownership change, and decommissioning and river restoration. In recognition of the interdependency of multiple river hydros on a shared river, the prosperity groups formed according to river systems.

The local conveners, Consumers Energy Community Affairs managers, and PSC developed participant lists to have diverse stakeholders (e.g., economic development, river or watershed groups, anglers, recreational users, local governments, tourism associations, and relevant state and federal agencies) that are representative of each community. Community Affairs managers participated as members and liaisons between the groups and company leadership. The conveners served as the local hosts and meeting facilitators; in some communities where local facilitators were unavailable, PSC played this role. Exhibit 3 shows the groups and their local conveners.

EXHIBIT 3. Prosperity Groups in 2024

Prosperity Groups	Local Convener
Mio	Big Creek Township Supervisor (with PSC)
Alcona	Curtis Township Supervisor (with PSC)
Cooke, Foote, Loud, and Five Channels	Iosco County Controller/Finance Director (with PSC)
Webber	Ionia Conservation District
Calkins Bridge	Outdoor Discovery Center (ODC) Network
Tippy and Hodenpyl	Alliance for Economic Success (AES)
Rogers, Croton, and Hardy	Omni Tech International

Purpose and Activities

The prosperity groups developed their communities' priorities for the three potential scenarios for the river hydros: Consumers Energy relicenses and continues operation, a new owner continues operation, or Consumers Energy pursues dam decommissioning and river restoration. The prosperity groups met four times in 2024 to identify their community assets in relation to the river hydros with the goal of delivering their priorities to Consumers Energy by the end of 2024.

Each group was tasked with delivering a set of ideas that Consumers Energy could support in three scenarios:

1. **Relicensing**—How would the prosperity group like Consumers Energy to build a community benefits package in the next relicensing period?
2. **Sale**—What would the prosperity group like Consumers Energy to ask for on behalf of the community should a sale occur?

3. **Decommissioning**—What are the key investments the prosperity group would like Consumers Energy to make to support the long-term prosperity of the community post-impoundment?

The groups began meeting in April 2024 and are positioned to continue meeting through completion of exiting (either through sale or decommissioning) or relicensing. They met in person to learn more about the many issues inherent to each scenario, discuss their concerns and questions among their groups and in conversation with Consumers Energy, and respond to specific questions for each meeting. Exhibit 4 presents the meetings' workflow. Additionally, at each meeting, Consumers Energy representatives provided updates germane to the river hydros, answered questions from group members, and participated in the groups as a stakeholder.

EXHIBIT 4. Workflow for Prosperity Group Planning in 2024

MEETING ONE Community Strengths/Assets	MEETING TWO Opportunities	MEETING THREE Results	MEETING FOUR Setting Priorities	Deliverables
Focus Question What are the existing strengths/assets in the community?	Focus Question Which strengths/assets can we build upon with the dam? Without the dam? *Optional:* Content area expert presentation	Focus Question What is Consumers Energy's role in helping us reach our community's aspirations? *Optional:* Content area expert presentation	Focus Question How will we reach our community's aspirations? *Optional:* Content area expert presentation	Values Statements for Three Scenarios • Removal • Relicensing • Sale

During the first meeting, the prosperity groups completed two items. The first was a community asset mapping activity to identify the community's existing strengths and assets. The second was a survey to determine knowledge gaps of the groups. Subsequently, content area experts were invited to present at meetings based on the survey results.

During the second meetings, the groups identified community opportunities and assets to leverage if the dam is relicensed and if the river was undammed. The results of the community asset mapping activity from the first meeting served as the starting point for identifying opportunities. Groups also began inviting content area experts to build the group's knowledge and understanding of specific topics.

The groups identified ways to strengthen community prosperity under the three scenarios (relicense, removal, and sale) during the third meetings as well as key actions and resources needed to support those ideas. As part of the activity, group members answered the focus question, "What is Consumers Energy's role in helping us reach our community's aspirations?" In addition, the groups continued hearing from content area experts during the meetings.

In the fourth and final meetings of 2024, the groups completed their community prosperity plan begun during the previous meeting and refined their ideas in response to the focus question, "How will we reach

our community's aspirations?" While some groups continued to build their understanding of specific topics by hearing from content area experts, all groups were intent on organizing their ideas or priorities into scenario-planning tables that PSC could include in its report to Consumers Energy.

Summary of the Work

Detailed summaries of the work of each prosperity group are provided below, but there were several overarching themes that arose across the seven groups.

Theme One: Health of the Local Fisheries

Group members shared their perspectives on local fisheries conditions with and without river hydros. In the scenario where the river hydros continue operations, some people stated that they value the existing fisheries found above the river hydros, where impounded waters host species adapted to that environment. Other respondents expressed concerns that native species will struggle to survive and thrive without free-flowing rivers. In the scenario where the river hydros are removed, some group members expressed concerns with no longer fishing lake-like waters. Some participants stated they were concerned that river hydro removal will mobilize contaminated sediments and other pollutants and thus harm fisheries. In the scenario where the river hydros are sold, group members voiced concerns that a new owner may not prioritize the health of the fisheries even to the extent that Consumers Energy does.

Theme Two: River Hydros Play an Outsized Role in Local Economies

Most of Consumers Energy's 13 river hydros are in rural areas with limited economic diversification. Over the past century since the river hydros' construction, communities, businesses, and school districts have grown alongside and in response to them. Prosperity groups discussed the outsized role the river hydros have on their local economies where large impoundments provide lake-like recreation for residents and visitors, support small businesses related to recreation, may augment real estate valuations, and impact the number of school-age youth served by the school districts.

Theme Three: Dependence on Outdoor Recreation for Rural Economies

Prosperity group members identified natural resources, scenery, and outdoor recreation opportunities as top community assets. Those assets contribute to a pride of place, sense of community, and sources of income and economic activity from year-round outdoor recreation. Natural assets—including forests, wildlife, waterways, lakes, and scenic views—bring tourists to the communities and drive rural economies.

Theme Four: Viability of Maintaining the River Hydros for Another FERC License Period

Group members understand Consumers Energy's challenges related to continued river hydro maintenance and operation as federal licensing requirements increase. Consumers Energy has been transparent about the costs to safely operate and maintain the river hydros, upcoming maintenance needs, and expectation for new requirements from FERC that likely will increase costs. Members frequently stated that the company or a new owner would need to have the ability and finances to maintain the river hydros for another 30- or 40-year license period.

Theme Five: Uncertainty About a New Owner's Ability to Safely Maintain the River Hydros

Prosperity groups expressed consternation about the possibility of a new owner purchasing the river hydros. While Consumers Energy has a longstanding presence in the communities as the primary energy

utility and has existing relationships with group members, so much is unknown about a potential new owner or owners. Generally, Consumers Energy is viewed as a trusted partner that shares many residents' priorities for the communities. Participants stated their uncertainties about the intentions of a new owner of the river hydros and concerns that they will have little leverage to advocate for community priorities.

Theme Six: Land Management Strategy if the River Hydros Are Removed

If the river hydros are removed, who would own previously submerged lands? What activities would be allowed on those lands? How would those lands be restored and managed? Can trails be moved or added to adjust to the new water elevation? Group members asked these questions and many more related to land use decisions that would need to be made if the river hydros were removed. Because of these uncertainties, the groups often identified the development of a land management strategy as an early step to take with Consumers Energy, should the decision be made to decommission and remove any river hydros.

Theme Seven: Better Promotion and Marketing of These Regions

By developing the prosperity groups and giving them space and structure to discuss their river hydro–related priorities, several themes and needs emerged such as the need for better promotion and marketing of the river hydro communities and regions. Most groups invited experts in economic development and rural prosperity into their meetings to provide information, resources, and supports as they move forward with the prosperity plans. Regional economic development organizations and the Michigan Office of Rural Prosperity were some of the entities tapped by participants for future community planning initiatives in response to changing demographics in rural Michigan. Marketing and promotion campaigns will flow from those efforts.

Theme Eight: More Investment in Outdoor Recreation

Regardless of the river hydros' fate, the groups prioritized expanding and improving outdoor recreation opportunities and thoughtfully increasing public access to rivers, impoundments, and other outdoor areas. Participants noted their communities will need to be resilient to the changing climate and adapt snowmobile trails so other trail users can benefit when snowfall is low. Planning, developing, and marketing nonmotorized water trails was identified as another opportunity that requires funding and other resources. Some groups prioritized maintaining and securing large undeveloped parcels for diverse wildlife habitat and outdoor recreation use.

Potential Risks

PSC identified several potential risks related to engagement activities for Consumers Energy's awareness as it considers the prosperity groups' work products in the context of the long-term river hydro strategy. Below are our suggested opportunities for Consumers Energy to mitigate the risks as it goes forward.

Risk One: Delayed Decision Making About the River Hydros

Consumers Energy announced to the prosperity groups it would announce decisions about the river hydros near the end of March 2025. Many prosperity group members said it was frustrating not having the information on a decision during the prosperity group meetings. If the decision is delayed much beyond the anticipated date, some key stakeholders, community members, and community leaders likely will respond acrimoniously and publicly.

Risk Two: Confusion About Who Has Decision-Making Responsibility

As owner and operator and FERC license holder, Consumers decides the river hydros' futures. Prosperity groups act in an advisory capacity to Consumers Energy. Nevertheless, group members frequently shared their preferred scenarios in meetings and in statements to Consumers Energy and to FERC. To mitigate this risk, Consumers Energy will need to continue clearly communicating expectations for the groups and that the decisions about the river hydros rest with the company.

Risk Three: Community and Key Stakeholder Disengagement

Even after three years of deep engagement with the river hydro communities, the need remains for Consumers Energy to continue building trust with the communities. Some prosperity group members declined to participate in all meetings, stating that they felt their perspectives would not be considered. The company should continue to be transparent and timely with sharing information about the river hydros and tailor methods of communication and messaging to specific groups. In addition, Consumers Energy regularly leads and participates in community-specific projects not connected to the river hydros; sharing news of such projects will provide them with a more holistic view of what the utility and its personnel do in and for residents. Company representatives should continue regularly meeting with elected and appointed community leaders to maintain open lines of communication about the river hydros and other utility-related matters.

Risk Four: Opaque Decision-Making Processes for River Hydro Relicensing, Sale, or Decommissioning

Regardless of Consumers Energy's decisions regarding the river hydros, the company will need to demonstrate its commitment to transparency in presenting the decisions and the subsequent processes and time frames. Community and stakeholder representatives want Consumers Energy to integrate prosperity group members into the processes of relicensing, sale, or decommissioning. They and the broader public also would benefit from having simple illustrations about the decision points and milestones associated with each of the three scenarios.

Risk Five: Selling the River Hydros

Of the three scenarios examined by the prosperity groups, the possible future in which the river hydros remain but are owned by a new entity elicited the most concern. Even among group members that expressed that they would like to see the river hydros remain stated that a new owner brings continued uncertainty about values alignment with the communities and what new ownership means for the communities and in the mid and long term. Some of these concerns could be assuaged by clearly explaining what the process would look like and including community and stakeholder representatives in the process in a meaningful way to maintain productive relationships with its customers throughout Michigan.

Next Steps

The prosperity group members we heard from are anxious for Consumers Energy to make and announce its decisions about the river hydros after living with three years of uncertainty. They are ready to move forward and have agency to build their preferred visions of prosperity.

Consumers Energy expects to announce its decisions about the river hydros' futures around the end of March 2025. Our recommended next steps for how the company can engage with the communities and key interested parties are aligned with Consumers Energy's ongoing commitment to transparency and the company's triple bottom line of people, planet, and prosperity. Further, the following recommendations recognize the interests and desires we heard from group members.

- Disseminate Consumers Energy's decisions about the river hydros to the prosperity group conveners and members in a timely manner.
- Host community public meetings for all 13 river hydros within two weeks following Consumers Energy's decisions.
- Support meetings of the prosperity groups, which will need to reconvene after the community meetings to discuss the role of their groups and the chosen priorities during spring and fall in-person meetings. The decisions on Consumers Energy's continued operations of the river hydros will guide the frequency and purpose of prosperity group meetings.
    - **If the decision is to sell,** hold a meeting to discuss the sale and the anticipated next steps.
    - **If the decision is to decommission and remove,** hold a meeting to discuss the decision, understand the timeline and studies that will be needed, identify and invite experts from Consumers Energy to discuss key topics, and discuss what community representation is needed for the process.
    - **If the decision is to relicense,** hold a meeting to discuss the decision, then pause the group until Consumers Energy is closer to the relicensing time frame. Subgroups could form and meet on the different relicensing topics.

No matter what Consumers Energy decides regarding the river hydros, not everyone will support the decisions. More to the point, there will be opposition to any decision made. The company can prepare for the next phase of the conversation by focusing on transparency in all communications, open discussion, and a thoughtful process that includes the priorities of the prosperity groups among its considerations.

Prosperity Group Priorities

The culmination of the prosperity groups' activities in 2024 are the priorities each group identified as being important to their communities' prosperity under the three potential scenarios for the river hydros. This section presents the priorities by group along with maps of each group's area of interest in alphabetical order by river. The order in which the priorities are displayed are not indicative of importance. In some instances, the information has been provided by the groups' conveners.

Au Sable River

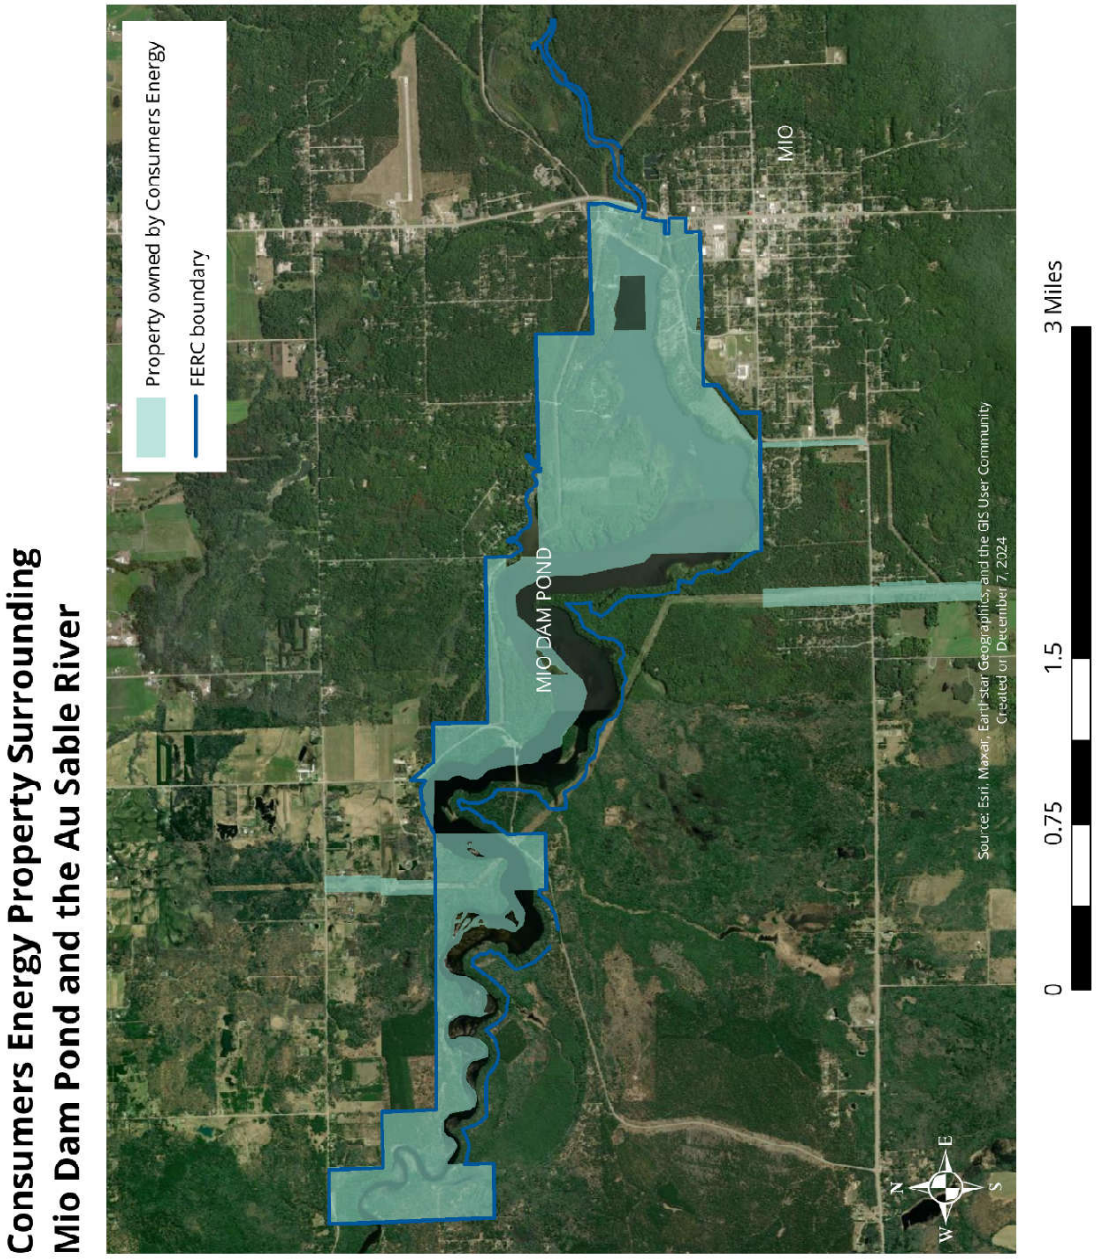
Three prosperity group formed to discuss the six Consumers Energy–owned river hydros on the Au Sable River. The Upper Au Sable group focused on Mio Dam (Exhibit 5), the Middle Au Sable group focused on Alcona Dam (Exhibit 7), and Lower Au Sable group focused on the four dams in Iosco County: Cooke, Foote, Loud, and Five Channels (Exhibit 9). PSC provided facilitation services to these groups in cooperation with local government partners.

Mio Dam

Outdoor Recreation; Fishery Protection and Restoration; Dam Safety

The Upper Au Sable prosperity group identified **outdoor recreation** as the surrounding community's greatest asset; recreational opportunities are inextricably linked to the community's long-term prosperity. This is a priority in all three scenarios. If Mio Dam remains, group members prioritize expanding recreational opportunities and increasing the number of visitors to the area through a marketing campaign. Recreational opportunities were recognized as having impacts on local quality of life and tourism, which drives the economy. If the hydro facility remains but changes ownership, recreational opportunity expansion and marketing are still top priorities. If Mio Dam were to be removed, the group would support expanded recreational opportunities made possible by a free-flowing river and newly emergent lands.

The prosperity group identified **fishery protection and restoration** as another priority for the area's prosperity. Anglers are an important part of the area's tourism base and the local community, and members of this group value a healthy environment and natural resources. Whether Mio Dam is relicensed by Consumers Energy, is sold to another buyer, or is decommissioned, improving the health of the Au Sable River fishery and providing access to the public are important to the group members.



This group identified several priorities related to **dam safety, long-term maintenance, and lease arrangements** in the event of a sale. They noted that, because the new owner would not have a track record of being a good partner in the community, they would want the owner to demonstrate investment in dam safety and show that they had a fiscal plan for eventual dam removal. Citing other dams that have failed or been abandoned in Michigan, they worried that the new owner would abandon the dam when it was no longer profitable, leaving local governments with the responsibility of maintaining or removing the facility. Members also seek some assurance that current leases would be honored and renewed by the new owner, as they presumably would be if Consumers continued to own the dams. In this scenario, they requested that Consumers negotiate with the buyer to guarantee not only the transfer of current leases until the end of the current license period, but the renewal of those current licenses and leases through the next license period as well.

In the event Consumers Energy decides to remove Mio Dam, group members prioritized studying the potential effects that lowering the water table may have on wells, along with concerns about property values and water access. In addition, group members agreed that significant planning and communication would need to be done to transition the community into its new state.

Representatives from these groups participated in the prosperity group formed for Mio Dam:

- Anglers of the Au Sable
- Big Creek Township
- Consumers Energy
- Hinchman Acres
- Huron Pines
- Michigan Department of Natural Resources
- Office of State Senator Michele Hoitenga
- Oscoda County Chamber of Commerce
- Oscoda County Clerk
- Oscoda County Economic Development Corporation
- Save the Dams
- Trout Unlimited
- United States Forest Service

EXHIBIT 5. Consumers Energy Property Surrounding Mio Dam and Pond and the Au Sable River

The Upper Au Sable: Mio Dam prosperity group's priorities for the three scenarios, key actions to advance the priorities, and launch steps for those actions are presented in Exhibit 6. Items listed for Scenario Two below are in addition to Scenario One items, ideally.

EXHIBIT 6. Upper Au Sable: Mio Dam Group Prosperity Plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Expand recreational opportunities	Build more access to the river/lake, improve existing access points	Approval from Manistee-Muskegon-Au Sable Coordination Team (MMAC) and FERC, investment from Consumers; add this to the recreation portion of the land management plan
	Build more trails, especially those accessible to outdoor recreation vehicles (ORVs) Prioritize town-to-town trail systems Biking/hiking trails on the north side of the pond	Change land management plan to allow ORVs, limit them to specific use areas Need investment from Consumers outside of the traditional recreation plan
	Build a new boat launch downstream of the Camp 10 bridge (tall boats can't pass under the bridge)	Need approval from MMAC and FERC.
Ensure dam safety	Continue to maintain the dam and surrounding lands with sufficient funding for safety	Continue to apply for grants and loans
Develop additional parks	Use Consumers-owned land to build a new park on the north side of the pond, with preference for designation as a state park	Approval from MMAC and FERC; need to develop a plan and negotiate with the DNR or county
Market the region as a recreational destination	Develop a marketing plan that involves Consumers, DNR, and the U.S. Forest Service Continue and build upon the Au Sable Canoe Marathon	Community committee: Oscoda County Chamber and Economic Development Corporation, DNR, Forest Service, and Consumers Funding from Consumers
Protect the fisheries	Explore ways to lower water temperature in and downstream of the impoundments	Consultants and experts in the field, approval from MMAC and FERC, funding from Consumers
	Continue run of river operations required under the federal Clean Water Act	
	Invest in research to understand wild brown trout populations below the dam	Habitat improvement account or direct funding for the study, nonprofit organizations
	Build fish ladders on every dam up to Mio	Conduct a feasibility study including the U.S. Fish and Wildlife Service, Great Lakes Fishery Commission, and other nonprofits

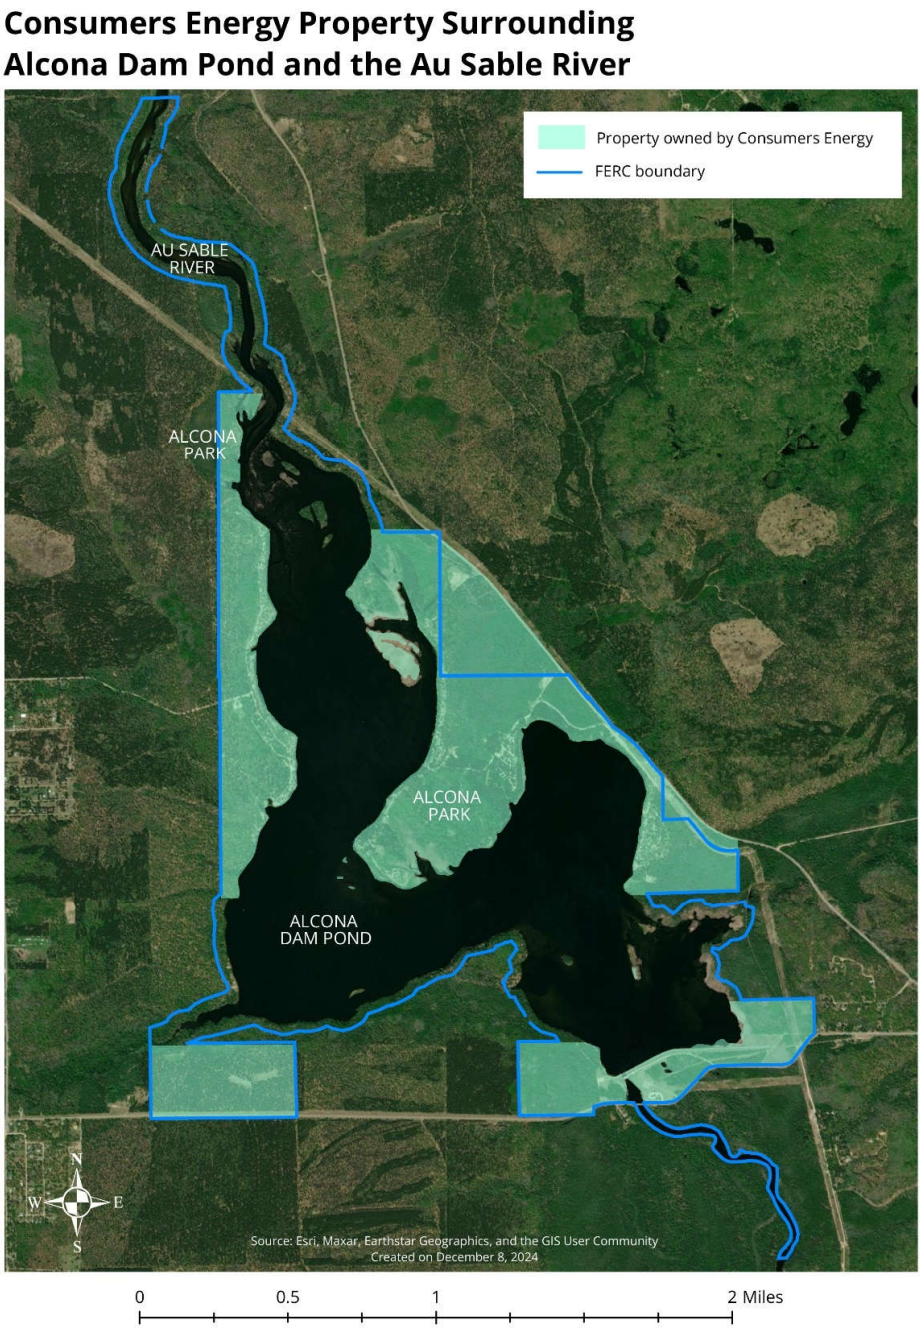
Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Protect leaseholders	Transfer land licenses and leases (e.g., Oscoda County Park) from Consumers to the new owner	Negotiated as part of the sale agreement between Consumers and the buyer
	Require new owner to extend current licenses and leases through the next relicensing period	Negotiated as part of the sale agreement between Consumers and the buyer
Plan for the next 50–100 years of dam operation	Implement a bond or other surety for the new owner's responsibility for safe operation and eventual dam removal	Requirement of the sale agreement
	Delineate the responsibilities of the new owner	Consumers should create a public-facing document summarizing responsibilities
	Build funding for dam maintenance and upgrades into the power purchase agreement	Requirement of the sale agreement
Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Plan for the transition and new state	Develop a land management plan that includes bottomlands and surrounding lands and prioritizes keeping land in public ownership	Consumers convene a group to develop a land management plan; clarify and amend state Natural Scenic Rivers requirement to include FERC lands
	Ensure community involvement in feasibility study, communicate results to understand the impact of removal	Have public meetings, continue prosperity groups, include artistic renderings of river restoration and community post-removal, consider creative uses for existing infrastructure
	Compensate local business owners for lost revenue and value through the transition period	Consumers creates a community fund
Expand recreational opportunities	Build nonmotorized trails on the exposed bottomlands with access points and connect to larger trail system	Convene community to create a plan, which should be incorporated into the township recreation plan and county master plan; ensure coordination so lands are not committed twice
	Keep the land public and undeveloped	Meet with local, state, and Forest Service officials to determine how to transition the land
Protect property owners	Mitigate any effects of removal on wells	Inventory wells, conduct an impact study, create a mitigation fund
	Ensure that those who have river access now still have it after removal	Offer portions of bottomlands to owners for access, determine how to offset initial cost and tax increases
	Compensate lakefront property owners for any lost property value, protect from unexpected tax increases due to increased acreage	Study to determine property values pre- and post-removal; develop a community fund

Alcona Dam

Outdoor Recreation and Nature; River Health; Dam Safety

The Middle Au Sable prosperity group recognized **outdoor recreation and nature** as key to the community's long-term prosperity. In the scenario where Alcona Dam remains and Consumers Energy maintains ownership, the group prioritizes increasing outdoor recreation opportunities to improve residents' quality of life and tourist activities. If the dam is sold, the group expects the community will still want to expand outdoor recreation and improve river health. The group agreed that increasing recreational opportunities would be a priority under this scenario, including trails, fishing, and wildlife viewing.

The group prioritized **improving river health** across all three scenarios because a healthy river system is essential to tourism and community prosperity. They also seek to ensure a healthy ecosystem post-removal where restoration occurs of the river floodplain, historic plant communities, and natural features.



Tourism drives the local economy, so the community could benefit from a marketing campaign as an outdoor recreation destination under all three scenarios for Alcona Dam. If the dam was removed, group members would like to pursue economic diversification through regional coordination and possible repurposing of existing river hydro infrastructure.

The group emphasized the need for **continuing safe dam operations.** They recognize Consumers Energy as a reliable partner, especially when it comes to operating the dam safely, but also saw room for improving communication between Consumers and the broader community. If the dam is sold, group members expressed concerns about a buyer's ability to maintain the dam, and the possibility that a buyer would abandon the dam when it was no longer profitable, rather than removing it responsibly. They also suggested additional ways that the buyer could build relationships in the community.

Representatives from these groups participated in the prosperity group:

- Alcona County
- Anglers of the Au Sable
- Consumers Energy
- Curtis Township
- Curtis Township Library
- Curtis Township Planning Commission
- Eagle Ridge Golf Course
- Glennie Sportsman Club
- Heritage House Realty
- Huron Pines
- Michigan Department of Natural Resources (DNR)
- Office of State Senator Michele Hoitenga
- Trout Unlimited

EXHIBIT 7. Consumers Energy Property Surrounding Alcona Dam and Pond and the Au Sable River

The Middle Au Sable: Alcona Dam prosperity group's priorities for the three scenarios, key actions to advance the priorities, and launch steps for those actions are presented in Exhibit 8. Items listed for Scenario Two below are in addition to Scenario One items, ideally.

EXHIBIT 8. Middle Au Sable: Alcona Dam Group Prosperity Plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Expand recreational opportunities, increase public access to the river and lake	Expand trails, including ORV, multiuse, horse, and water trails; explore the possibility of pursuing water trail designation	Approval from MMAC, FERC, and DNR; investment from Consumers Build a "friends of" organization to assist with maintenance
	Improve the fishery via habitat management	Consumers add a bubbler to the pond DNR and the US Forest Service add coarse woody debris
	Inventory access points, plan for improving existing points and filling gaps	Identify and secure funding for the inventory Huron Pines could do the inventory USFS, DNR, and Michigan Trails & Greenways Alliance would also be involved
	Explore grants to increase boating and kayaking opportunities	Team effort—led locally, Huron Pines can assist. Planning help from the Michigan Office of Rural Prosperity; continue Au Sable Canoe Marathon
Maintain a healthy river corridor	Continue or expand Habitat Improvement Account	Consumers with planning assistance from the Office of Rural Prosperity
	Create a river management and stewardship organization	Need a lead organizer
	Monitor water quality, sediment, erosion, invasive and threatened/endangered species	Resource agencies and Huron Pines would be involved
Continue Consumers Energy's Habitat Improvement Account (HIA)	Expand HIA by adding fish loss from factors other than entrainment to the calculation	Consumers, MMAC, FERC would be involved
	Expand HIA calculation to include species other than fish	Identify supplemental grant opportunities
Continue dam safety measures and community's relationship with Consumers Energy	Maintain current safety practices	Consumers; continue to apply for safety grants and loans
	Increased communication with Alcona Park	Consumers Hydro Land Management attend Alcona Park board meetings periodically and as invited
	Maintain transparency about operations with the public	Consumers communicate information about dam operations or events

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key actions**	**Launch step**
Maintain dam safety into the future	Implement a bond or other surety for the new owner's responsibility for safe operation and eventual dam removal	Consumers negotiation with buyer
	Build funding for dam maintenance and upgrades into the power purchase agreement	Consumers negotiation with buyer
Build a working relationship with the new dam owner	Maintain lease agreements through the next license period	Consumers negotiation with buyer; Curtis Township to have the option to participate in negotiations related to Alcona Park
	Open lines of communication between the new owners and the community	Buyer attends local government meetings periodically to update community about dam operations; creates and updates Alcona Dam Facebook page

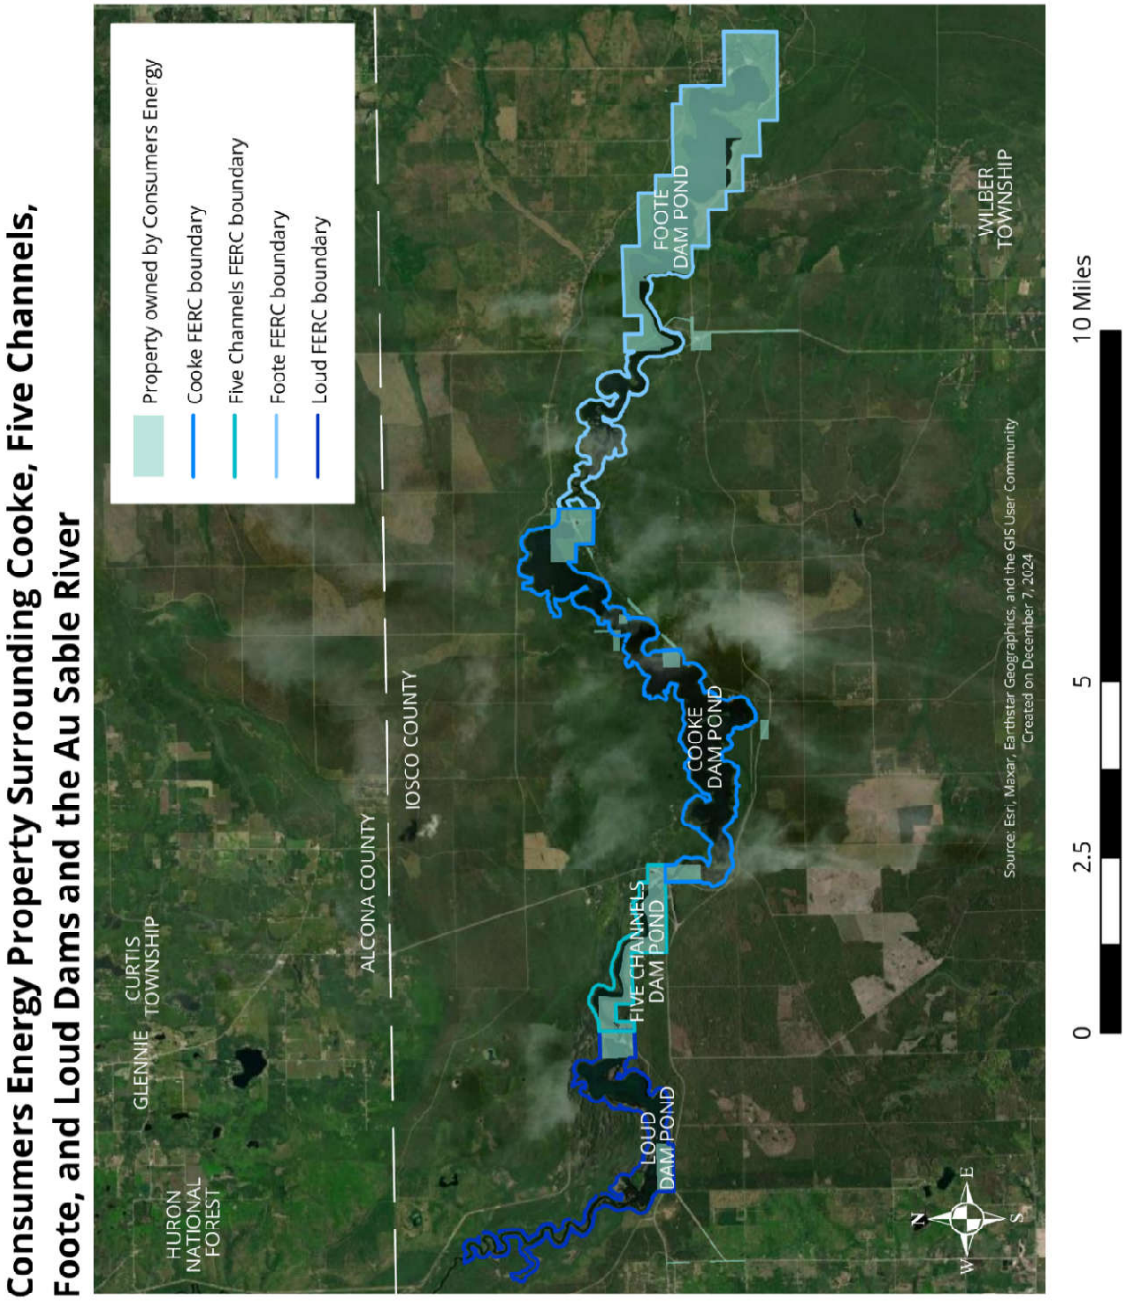
Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Increase year-round recreation, shifting to more land- and river-based activities	Build hiking and biking trails in the bottomlands	Consumers, MMAC, and FERC are involved
	Transition snowmobile trails to include ORVs, link to regional trail network	Consumers, MMAC, and FERC are involved
	Create recreation management plan	Consumers, MMAC, and FERC are involved
	Increase ADA-compliant access points	Consumers, MMAC, and FERC are involved
Create and build on opportunities that preserve or increase unique habitat and wildlife	Develop a land management plan covering wildlife habitat and threatened/ endangered species	Consumers, MMAC, and FERC as part of the decommissioning plan, local conservation groups
	Expand designation of the Wild and Scenic River beyond current boundaries	USFS and Consumers are involved
	Restore wetlands, oxbows, and floodplain in bottomlands	Consumers, MMAC, and FERC as part of the decommissioning plan, local conservation groups
	Remove or treat invasive plant species, restore historical plant communities	Huron Pines could conduct invasive species inventories, treatments for their removal, and increase native plant diversity
Restore the cold-water fishery	Plantings at the river edge; habitat structure and stream modification	Consumers, MMAC, FERC, and local conservation groups
	Monitor fish communities and channel morphology before and after dam removal	Consumers, MMAC, FERC, local conservation groups, outside researchers, and universities
	Research and stewardship opportunities for people in the community	Consumers, MMAC, FERC, and local conservation groups

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Pursue economic diversification and the potential for new industries and businesses	Develop a marketing plan for the area as a recreation destination	Consumers, Alcona community, Northeast Michigan Council of Governments, funding from the Office of Rural Prosperity
	Develop a vision for repurposing the dam structures	Potential buyer of the powerhouse, Consumers, DNR Natural Rivers; need a feasibility study
	Research developing an Au Sable River Council made up of counties, local nonprofits, etc.	Consumers, local conservation nonprofits, DNR, USFS, Alcona County Potential for members to be appointed by the governor
	Develop a marketing plan for the area as a recreation destination	Consumers, Alcona community, Northeast Michigan Council of Governments, funding from the Office of Rural Prosperity

Lower Au Sable: Cooke, Foote, Loud, and Five Channels Dams

Tourism; Dam Safety; Invasive Species Prevention

The Lower Au Sable River prosperity group prioritized opportunities and investments to **bring more year-round tourism to the region.** While this section of the Au Sable River has more economic diversity than the middle and upper sections, with Wurtsmith Air Force Base and two towns on Lake Huron, group members noted that much of the tourism–which remains the most important economic engine for the region—is tied to the river hydros and the Au Sable River.



While **safe operations of the river hydros** are a priority for the group across all three scenarios, it is a top priority if a sale occurs. Group members seek assurance that a new owner can continue safe operations and have the financial or technical wherewithal to provide the same or better level of care and upkeep than Consumers Energy.

Under a decommissioning scenario, the group prioritized **invasive species prevention** and the need to identify and develop different **outdoor recreation and tourism** opportunities. The group also discussed the financial impact that scenario could have on some of the county parks and campgrounds.

Representatives from these groups participated in the prosperity group:

- Bissonette Landing Homeowners Association
- Charter Township of Au Sable
- Consumers Energy
- Develop Iosco
- Great Lakes Fishery Commission
- Iosco Conservation District
- Iosco County
- Michigan Department of Natural Resources
- Michigan Hydro Relicensing Coalition
- Old Orchard Park
- Oscoda Area Schools
- Oscoda Township
- Oscoda Township Parks and Recreation
- Pine Acres
- Plainfield Township
- Saginaw Chippewa Indian Tribe
- Save the Dams
- Office of State Senator Michele Hoitenga
- Seven Mile Hill Homeowners Association
- Wildcat Gulley Homeowners Association

EXHIBIT 9. Consumers Energy Property Surrounding Cooke, Five Channels, Foote, and Loud Dams and Ponds and the Au Sable River

The Lower Au Sable: Cooke, Five Channels, Foote, and Loud Dam prosperity group's priorities for the three scenarios, key actions to advance the priorities, and launch steps for those actions are presented in Exhibit 10. Items listed for Scenario Two below are in addition to Scenario One items, ideally.

EXHIBIT 10. Lower Au Sable: Cooke, Five Channels, Foote, and Loud Dams Group Prosperity Plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Expand/protect current recreation opportunities	Expand access and handicapped access, especially at Foote site	Consumers Energy, Manistee-Muskegon-Au Sable Coordination Team (MMAC), and the Federal Energy Regulatory Commission (FERC)
	Expand parking at boat launches	Consumers Energy, MMAC, and FERC
	Inventory properties and assets	Consumers Energy, MMAC, FERC, and community stakeholders (i.e., local governments)
	Develop a recreation management plan for the four dams	Consumers Energy and community stakeholders
Ensure dam safety	Continue transparency between Consumers Energy and the community	Consumers Energy: "Toot your own horn" and promote all the contributions made in regular updates to the community Local governments will invite Consumers Energy to board meetings at a frequency to be determined
	Develop a long-term process for safety	Consumers Energy
Maintain and increase access to the waterway and the land around it	More and bigger boat launches, kayak launches	Include in the recreation management plan; Consumers Energy, MMAC, and FERC
	General improvement of current sites	Include in the recreation management plan; Consumers Energy, MMAC, and FERC
	Renovate access sites to be Americans with Disabilities Act (ADA) compliant	Include in the recreation management plan; Consumers Energy, MMAC, and FERC
	Ensure current license and leaseholders (e.g., Old Orchard Campground) keep access as it currently exists	Consumers Energy
Increase promotion of Iosco County as a year-round destination to live, work, and play	Develop a marketing plan	Develop Iosco, Oscoda Chamber of Commerce, convention and visitors bureaus (CVBs), Iosco County, local townships, Northeast Michigan Council of Governments (NEMCOG)
	Social media, statewide promotion	Develop Iosco, Oscoda Chamber of Commerce, CVBs, Iosco County, local townships, NEMCOG
	Develop and enhance partnerships Continue and build on Au Sable Canoe Marathon	Michigan Office of Rural Prosperity, Alcona County, Oscoda County, communities along the Au Sable River from Mio to Oscoda, Huron Pines, National Park Service
	Continue and enhance opportunities for event sponsorship	Consumers Energy

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Strengthen and protect the fisheries	Conduct a fisheries study including ecological and engineering considerations	Consumers Energy and MMAC
	Ensure continued invasive species control	Consumers Energy and MMAC
	Address river flows for fish habitat	MMAC and FERC
	Develop more access for fishing opportunities	Consumers Energy and MMAC
	Build more boat wash stations	Consumers Energy, MMAC, FERC, and MSU Extension
	Address water temperature concerns	Michigan Department of Environment, Great Lakes, and Energy (EGLE), Consumers Energy, MMAC, and FERC
	Examine feasibility of fish ladders at all dams	Consumers Energy, MMAC, and FERC

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Protect current recreational opportunities and access	Expand access and handicapped access at all four dams, especially Foote Dam	Consumers Energy communicates priority to the new owner
	Expand parking at boat launches	Consumers Energy communicates priority to the new owner
	Inventory properties and assets as part of developing a recreation management plan for the four dams	Consumers Energy communicates priority to new owner
Ensure safe dam operations	Continue transparency between the dam owner and the community	Negotiations between Consumers Energy and new owner
	Confirm long-term process for safety	Negotiations between Consumers Energy and new owner
	Ensure financial viability of new owner to maintain the dams—implement a bond or other surety for the new owner's responsibility for safe operation and eventual dam removal	Negotiations between Consumers Energy and new owner
	Build funding for dam maintenance and upgrades into the power purchase agreement (PPA)	Negotiations between Consumers Energy and new owner
	Communication with local units of government	Negotiations between Consumers Energy and new owner
	Maintain community involvement	Negotiations between Consumers Energy and new owner

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Maintain all leases and licenses	Ensure Old Orchard Campground lease continues	Consumers Energy negotiation with new owner; recommend maintaining licenses and leases to the end of the FERC license
	Ensure current license and leaseholders keep access as it currently exists	Consumers negotiation with new owner; recommend maintaining licenses and leases to the end of the FERC license
Increase promotion of Iosco County as a year-round destination to live, work, and play	Develop a marketing plan	Develop Iosco, Oscoda Chamber of Commerce, CVBs, Iosco County, local townships, and NEMCOG
	Social media and statewide promotion	Develop Iosco, Oscoda Chamber of Commerce, CVBs, Iosco County, local townships, and NEMCOG
	Develop and enhance partnerships	Michigan Office of Rural Prosperity, Alcona County, Oscoda County, communities along the Au Sable River from Mio to Oscoda, Huron Pines, and National Park Service
	Identify opportunities for event sponsorships	Meet with new owner

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Protect adjacent landowners, local businesses, and local governments from financial impacts	Understand impacts and protect wells near impoundments	Consumers Energy as part of decommissioning planning
	Create a business remediation or support fund including communications about access during decommissioning process	Consumers Energy—grants to businesses, Michigan Office of Rural Prosperity, Develop Iosco, State of Michigan
	Develop a land management plan including inundated area (e.g., recreation, wildlife habitat, remediation, restoration plans)	Consumers Energy
	Conduct studies around decommissioning, including economic	Consumers Energy
	Develop a communications plan that includes community impacts and mitigation activities	Consumers Energy
	Develop an education plan so everyone understands the decommissioning process and rationale	Consumers Energy
	Determine bottomlands ownership	Consumers Energy
Preserve the area around the dams for public use	Develop a recreation plan including an evaluation of sites and best uses	Consumers Energy, Michigan Office of Rural Prosperity
	Enhance river access	

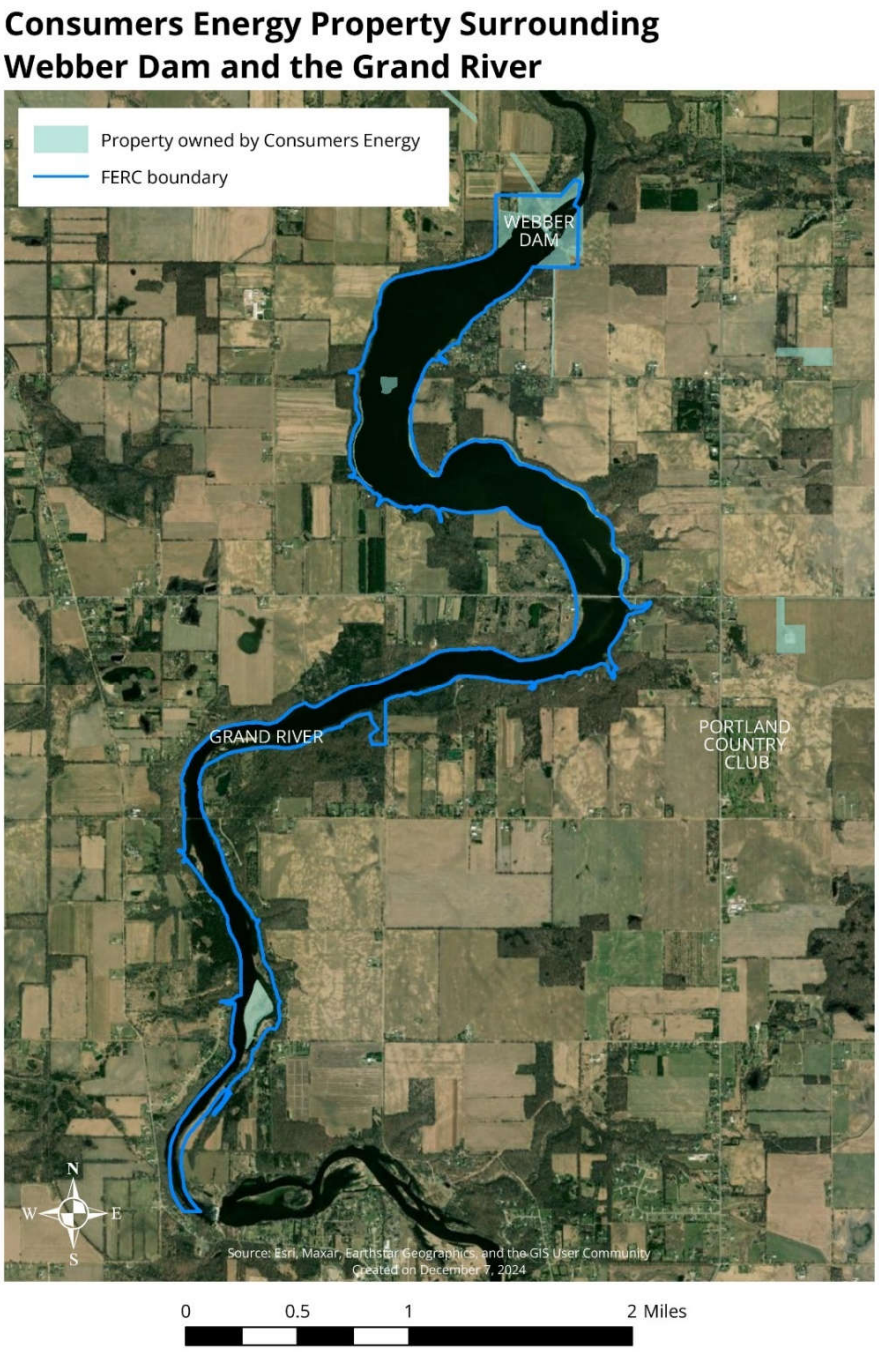
Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Develop and market the region as a year-round destination to live, work, and play	Develop a marketing and prosperity plan that includes clientele and markets	Consumers Energy, NEMCOG, Develop Iosco, local governments, chambers of commerce
Control invasive species	Conduct a fisheries study including feasibility in controlling invasive species	Consumers Energy, MMAC, Great Lakes Fishery Commission (GLFC), watershed group, friends group
	Non-aquatic invasive species control and management plan	Huron Pines, conservation districts
Explore new uses for the buildings associated with the dams	Conduct a study to determine if the powerhouses can be repurposed	Consumers Energy
Determine feasibility of maintaining any impoundments	Conduct a feasibility study to determine if local community could maintain an impoundment at any or all sites including operations, financials, and funding	Consumers Energy, local governments, GLFC, EGLE, U.S. Army Corps of Engineers

Grand River

Webber Dam

Outdoor Recreation; Tourism; Healthy River Habitat; Property Values and Taxes; Public Safety

The prosperity group identified **outdoor recreation and tourism** as priorities for community prosperity across all three scenarios for Webber Dam (Exhibit 11). Members expect opportunities for both priorities to increase under a dam decommissioning scenario and bring more opportunity for economic activity. **Healthy river habitat** was identified as a priority for environmental benefits and economic benefits since a healthy river encourages more recreation and tourism.



Property values and taxes were a priority for the group as Consumers Energy is the largest taxpayer in Lyons Township and residents want to at least maintain the current value of their properties. Little change would be expected in the scenarios where Consumers Energy relicenses the river hydro or sells it to a new owner. If the decision is to decommission, group members would expect a property assessment be done to determine ownership and real estate values.

Public safety in relation to river hydro operations was another priority. In the event of a sale, they are concerned that operations and maintenance by a new owner may put the community in danger. The community's history with cost of and liability of Lyons Dam and its subsequent removal is still fresh in the mind of the community, and they do not want to be held responsible for Consumers Energy choices. Group members noted the decommissioning scenarios offers the safest solution since the threat of a dam failure would be removed.

The Webber Dam prosperity group was facilitated by the Ionia Conservation District. Representatives from these groups participated in the prosperity group:

- City of Ionia
- Consumers Energy
- Great Lakes Fishery Commission
- Ionia County
- Ionia County Chamber of Commerce
- Ionia County Economic Alliance
- Lyons Township
- Michigan Department of Natural Resources
- Sessions Lake Equestrian Group
- Village of Lyons
- Village of Muir

EXHIBIT 11. Consumers Energy Property Surrounding Webber Dam and Pond and the Grand River

The Grand River: Webber Dam prosperity group's priorities for the three scenarios, key actions to advance the priorities, and launch steps for those actions are presented in Exhibit 12.

EXHIBIT 12. Grand River: Webber Dam Group Prosperity Plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Impoundment recreation continues	Fish ladder remains in effect, managing salmon population	DNR continues to operate fish ladder, potentially preventing spread of invasive species
	Current impoundment recreation includes some bass fishing and pleasure cruise with improvement	Consumers would continue to maintain the impoundment near the hydro facility and improve boat launch that provides access to the impoundment
	Improve downstream recreation including cold stream fishing, boating, kayaking	Community would like improved recreational opportunities, including trails, educational materials, and boat launches
The community continues to receive power from Consumers Energy	Current power generated is 1.3 megawatts per day	Consumers continues to maintain hydro facility, providing service to the region
	Cost of generation is greater than expense of maintaining the hydro facility	It would be in Consumers' best interest to find a solution to making the hydro facility profitable
	Other power sources may have other negative externalities and costs to the community	Wind and solar power would be new additions to the community, new partners would be developed, and a plan for future decommissioning of those facilities would be considered and required
Consumers continues to be largest taxpayer in Lyons Township	Consumers provides significant tax funding to Lyons Township	Consumers would continue to pay taxes as Lyons Township landowner
	No cost for removal would be required from any party	The Township, County, or State would not be responsible for any removal costs
Community maintains existing relationship with Consumers Energy	Consumers remains as a partner in Lyons Township and Ionia County	Consumers, Ionia County, and Lyons Township enjoy a relationship, functional at worst and symbiotic at best
	Consumers will continue to be involved in the community	Consumers continues to operate the facility
	Consumers will continue to provide power to the surrounding area from the hydro facility	Consumers continues to operate the facility and/or supply power even in the event of change
Property values remain the same	No change to the impoundment results in no change to properties on either side of the hydro facility	No action required; local landowners retain status quo of ownership
	Changes in property size could cause fluctuation in property value and tax assessments—this would not be the case if the properties remained the same	Consumers, a tax assessor, and survey team would be required if new property lines were to be drawn
	Those who currently have water access will continue to have access	Property owners are concerned about changes to water access and their existing docks—this would provide no change

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Need to develop trust with the new owner, potential to lose say in decisions around land use	A new third party could provide new solutions	Consumers, the community, and the third party would take an active role in solving future problems and providing prosperity to the community
	A new third party is unpredictable and does not have an existing relationship with the community	The community would have to navigate a new relationship with the existing memories from the Lyons Dam removal The third party is unpredictable, which is concerning to the community Consumers would need to be proactive in ensuring a new and loyal partner
New owner *could* bring new business and promotion	The new third party could theoretically provide new economic opportunities	This is also unpredictable and is concerning to the community Consumers would need to verify that the new owner would benefit the community

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Improve riparian habitat	Historical habitat restored, providing potential expansion for endangered species	A partnership between Consumers, DNR, and County would be active in ensuring responsible restoration
	Improved fishing for trout and salmon anglers	DNR and community members benefit from different riparian aquatic species
	Riparian wetland habitat can establish in new flood plain	Careful restoration and monitoring of the historical seedbank by the conservation district and DNR in the new flood plain upstream of the dam could result in rare habitat conservation
	Lower water temperatures increasing available dissolved oxygen, improving habitat	This project would align with other river restoration projects further downstream DNR would monitor habitat over time
Improved and diversified recreation	Increased numbers of community members using recreational facilities	Consumers and the community would work together to promote local recreation on the Grand River Improve trails and recreation, prioritizing ADA accessibility Install interpretive signs for education
	More recreational activities available	Boat passage would make traveling downstream easier, increasing opportunities for different types of angling DNR and the community would ensure safety and quality
	Higher quality of recreational activities available	Presently, the downstream access is used 3x more than the impoundment boat launch A new boat launch could include an ADA-accessible kayak/canoe launch

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
	Potential for new green spaces	DNR, conservation district, Consumers, and community could install a public green space that would be ADA accessible and include educational interpretive signage
Change in community property boundaries and personal residential values	A historical seed bank could be exposed on new property	DNR and conservation district would collaborate to ensure habitat conservation with Consumers funding
	Landowners could gain property	Landowners, township, surveyors, and tax assessors would determine any increase in property and its use Consumers would be active in stabilizing new landforms
	Property values are difficult to predict–some owners could lose the dock access and waterfront property Downstream properties could also be affected	Landowners, township, surveyors, and tax assessors would determine any increase in property and its use
	Assessment of other properties to determine future ownership	Landowners, township, surveyors, and tax assessors would determine any increase in property and its use A public greenspace could be installed
Safety in the short and long term	Safe removal of the facility is essential to the community	Consumers and DNR would hire any required contractors to ensure habitat, safety, and all proper procedures are followed for removal
	Knowledge that the facility will not fail if it is removed	Consumers and DNR would hire any required contractors to ensure habitat, safety, and all proper procedures are followed for removal
Hydro facility operating funds redistributed to benefit the community	Current funds to maintain the facility are not benefiting any parties	Consumers and community would discuss redistribution of funds
	Funds could be diverted to create new power generation infrastructure (current power generated is equal to two windmills)	Consumers can more efficiently change power generation infrastructure without the county needing to be as involved
	Community infrastructure creation	As a partner with the community, Consumers could fund community infrastructure projects

Kalamazoo River

Calkins Bridge Dam

Outdoor Recreation; Dam Safety; Retaining the Lake-Like Impoundment

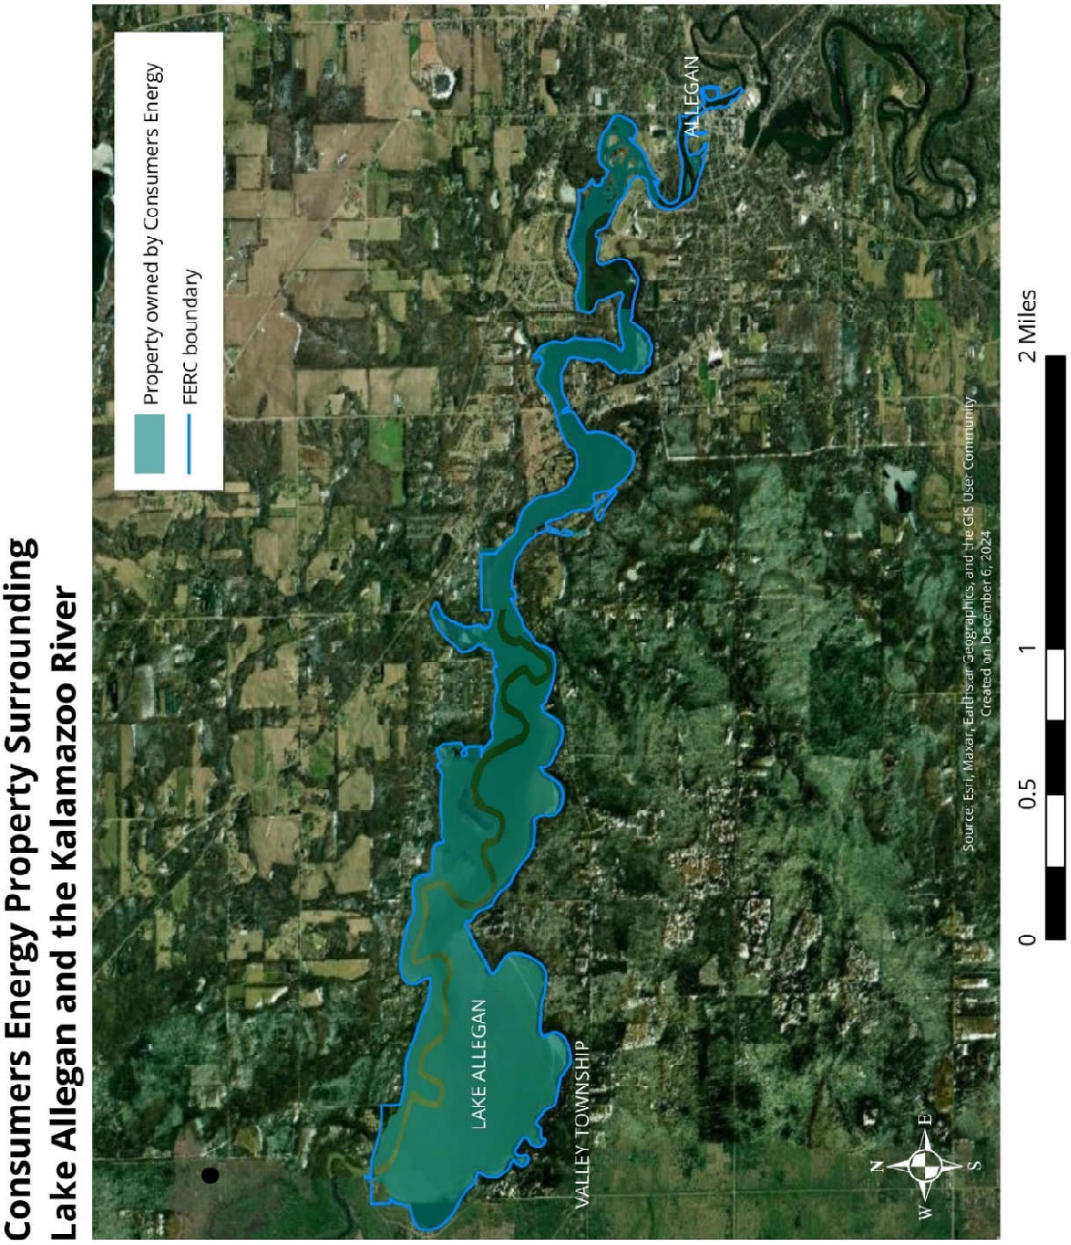
The prosperity group focused on the Calkins Bridge Dam and its impoundment, Lake Allegan, expressed their need for the several actions from Consumers Energy regardless of the company's decision:

- Consumers Energy to allow and empower group members to be an integral part and partner in the process of relicensing, sale, or decommissioning
- Assets that were previously public before the dam was sold to Consumers Energy ultimately be returned to the public trust once they are no longer used to generate power
- Consumers Energy to contribute financially to the community in support these efforts even if the company sells the assets to a third party to generate power

A priority for the group is **retaining the lake-like impoundment** under the relicense and sale scenarios. They would like to see the impoundment maintained and improved so that it and adjacent natural areas continue to benefit the local economy. Exhibit 13 shows the river hydro, impoundment, and surrounding area.

Maintaining and augmenting outdoor recreation opportunities and access is a priority across all three scenarios for the prosperity group. Property values, sense of place, and local economic activity are centered on close proximity and access to Lake Allegan and the river. Group members want to incorporate walkability and connectivity of trails and natural areas whether the impoundment is retained or not.

Group members also prioritized **safe operations and maintenance of the river hydro** as part of its prosperity plan. They are concerned with the facility's lifespan and what long-term maintenance would look like. In the event of a sale, a priority of the group would be to ensure that Consumers Energy would be a good community partner and that previously public assets that were sold as part of the dam to Consumers would be reverted to the public if power was no longer being generated.



In a decommissioning scenario, the group prioritized demonstrating progress on **PCBs remediation; preventing the spread of invasive species,** particularly sea lamprey; and **compensating waterfront property owners** for any devaluation of their property due to the loss of the lake-like impoundment.

The Calkins Bridge Dam prosperity group was facilitated by Outdoor Discovery Center Network. Representatives from these groups participated in the prosperity group:

- Allegan Conservation District
- Allegan Chamber of Commerce
- Allegan County
- Allegan Township
- City of Allegan
- Consumers Energy
- Great Lakes Fishery Commission

- Kalamazoo River Watershed Council
- Kalamazoo River Citizens Advisory Group
- Lake Allegan Association
- Michigan DNR
- Trout Unlimited
- U.S. Environmental Protection Agency
- Valley Township

EXHIBIT 13. Consumers Energy Property Surrounding Calkins Bridge Dam, Lake Allegan, and the Kalamazoo River

The Kalamazoo River: Calkins Bridge Dam prosperity group's priorities for the three scenarios, key actions to advance the priorities, and launch steps for those actions are presented in Exhibit 14.

EXHIBIT 14. Kalamazoo River: Calkins Bridge Dam Group Prosperity Plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key actions**	**Launch step**
Improve upon water and habitat quality within Lake Allegan to control invasive species and sediment contamination	Coordinate with EPA on long-term sediment cleanup and remediation	Consumers involvement in Superfund remediation Data sharing from Kalamazoo Watershed Management Plan–Kalamazoo River Watershed Council and CAG
	Work to control and remove invasive aquatic plants	Take meaningful steps to implement an invasive species control and management plan following Consumers invasive species study for 2024 Report the results of that 2024 study and tell the community specifically what Consumers will do to implement that plan Michigan Clean Water Corps members will be reporting on invasives and water quality of Lake Allegan Identify other partners to implement
	Further implement practices to reduce nutrient and sediment loading into the lake	Consumers should be part of the TMDL working group
	Create conditions for a healthier fish community including implementation of effective fish passage	Carp Derby 2025 – ODC, ACD, Lake Allegan Feasibility study of improving fish ladder that also prevents sea lamprey migration
Ensure property values continue to hold or increase their value	Continue to maintain dam with sufficient funding for safety	
	Seek to maintain character of lake area	Recreational plan for Lake Allegan Commercial development plan Invasive species management plan Allegan County Parks and Rec
	Develop long-term succession plan to maintain an impoundment	Master and recreation plans across townships/communities are in agreement Consumers commits to including conversion of the dam to a non-hydro structure, including funding that conversion, in any future delicensing decision or plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key actions**	**Launch step**
Continue to improve recreational tourism assets and maintain shoreline access to maximize benefits for Lake Allegan and residents of the area	Improve and update existing access points and recreational assets	
	Work with Allegan County Parks and DNR to identify additional opportunities for park space	Use Allegan County's New Richmond Park as a model
	Identify and develop additional access points	
	Collaborate with local/county agencies to promote Lake Allegan to broader public	Marketing plan–support from Consumers Allegan County Economic Development Commission Allegan Area Chamber of Commerce
Manage power generation through renovations to the powerhouse	Ensure dam operates effectively with nearby recreational uses	
	Ensure clear local understanding of property rights and easements	Document and communicate property ownership, tax information, and use with Lake Allegan community
	Determine projects and improvements that may qualify for grant funding	
	Establish recurring meetings between Consumers and local partners	
Develop a strategic community plan that brings municipalities together to build a well-connected lake community	Develop area-specific section of Kalamazoo River Greenway plan	Improve ability to portage canoes and kayaks from Lake Allegan to the river launch area below the dam Include potential canoe livery operators
	Connect relevant elements of Valley Township, City of Allegan, and Allegan County recreation and master plans	Include DNR to incorporate their facilities in the broader plan

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Acquirer is committed to the operation and function of the dam as an impoundment, not for other uses	Transfer land licenses and leases from Consumers to the new owner (e.g., Allegan County)	Part of sale agreement, negotiation between Consumers and new buyer Get the community involved early in the negotiation process
	Require new owners to extend current licenses and leases through the next relicensing period	Have Consumers negotiate this as part of the sale
	Work to gain the necessary first right of refusals to work through acquisition for a nominal price. Ensure that the lake and dam come back to the public at the end of the acquiror's use for power generation	County board Townships City of Allegan Allow local partners the opportunity to review transaction documentation and ensure an understanding that these are public assets
Define and acquire financial assets to secure the impoundment and fund other remediation efforts in Lake Allegan	Implement a bond or other surety for the new owner's responsibility for safe operation and eventual removal conversion of the dam to a non-hydro structure	Requirement of sale agreement Includes fish passage/lamprey exclusion upgrade
	Delineate the responsibilities of the new owner	CE create a public-facing document summarizing responsibilities (on the front end)
	Build funding for dam maintenance and upgrades into the power purchase agreement	Requirement of sale agreement
	Require a MOU/MOA with new owner for continued access and communication around the dam	Ensure long-term recreational usage of Lake Allegan GLFC
Implement a substantial remediation effort that prioritizes sediment management plan, invasive species management plan, and long-term habitat quality and aesthetics	Coordinate with EPA on long-term sediment cleanup and remediation	Consumers and new owner involvement in Superfund remediation Data sharing from Kalamazoo Watershed Management Plan–Kalamazoo River Watershed Council and CAG
	Work to control and remove invasive aquatic plants	Take meaningful steps to implement an invasive species control and management plan following Consumers invasive species study for 2024 Report the results of that 2024 study and tell the community specifically what Consumers will do to implement that plan Michigan Clean Water Corps members will be reporting on invasives and water quality of Lake Allegan Identify other partners to implement
	Further implement practices to reduce nutrient and sediment loading into the lake	Consumers and new owner should be part of the TMDL working group
	Create conditions for a healthier fish community including implementation of effective fish passage	Carp Derby 2025–ODC, ACD, Lake Allegan Feasibility study of improving fish ladder that also prevents sea lamprey migration

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Transition plan is created for Lake Allegan through the relicensing of the impoundment that is managed by the County or State	Funding sources are identified and included in the plan	Consumers creates a trust fund now, intended to support costs of the eventual transition to public ownership Include Georgia Pacific in planning
Create a recreational plan for long-term changes to the Kalamazoo River that is centered around walkability and a partnership with Allegan Parks and Rec	Develop area-specific section of Kalamazoo River Greenway plan	Improve ability to portage canoes and kayaks from Lake Allegan to the river launch area below the dam Include potential canoe livery operators
	Connect relevant elements of Valley Township, City of Allegan, and Allegan County recreation and master plans	Include DNR to incorporate their facilities in the broader plan

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Implement a substantial remediation effort that prioritizes sediment management plan, and long-term habitat quality and aesthetics	Engage with EPA around their long-term PCB cleanup efforts	
	Ensure community involvement in and communicate results of feasibility study to understand the impact of removal	Have public meetings, keep prosperity group; include artistic renderings of river restoration and community post-removal; consider creative uses for existing infrastructure Engage Lake Allegan Association
	Compensate local property owners for lost value through the transition period	CE create a community fund Community transition plan for businesses
Maintain property values and land management through enhancement of a flowing river-based economy	Compensate lakefront owners for loss of property value	Study to determine property value pre- and post-; develop community fund; compensate for removal of permanent structures along the lake
	Keep the land public, undeveloped, and developed only for public recreational use	Meet with local and state officials to figure out how to transition land

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Increase and promote safe access opportunities for paddle sports, fishing, and other recreational access	Ensure that those who have access to the river system now still have it after removal	Offer portions of bottomlands to owners for access, determine how to offset initial cost and tax increases
	Create additional access points	
	Investment in proactive management of wetland (ex. Conservation easement, Greenway plan)	Explore wetland mitigation bank Proactively restore floodplain areas at risk of takeover by nonnative species
Prioritize improving water resource management of groundwater and surface waters	Mitigate the effect of removal on wells by funding wells or other water infrastructure	Inventory wells, conduct study, create mitigation fund
	Ensure river following cleanup will connect well ecologically with rest of river	
Invest in recreation opportunities	Create a recreational plan for long-term changes to the Kalamazoo River that is centered around walkability and a partnership with Allegan Parks and Rec	

Manistee River

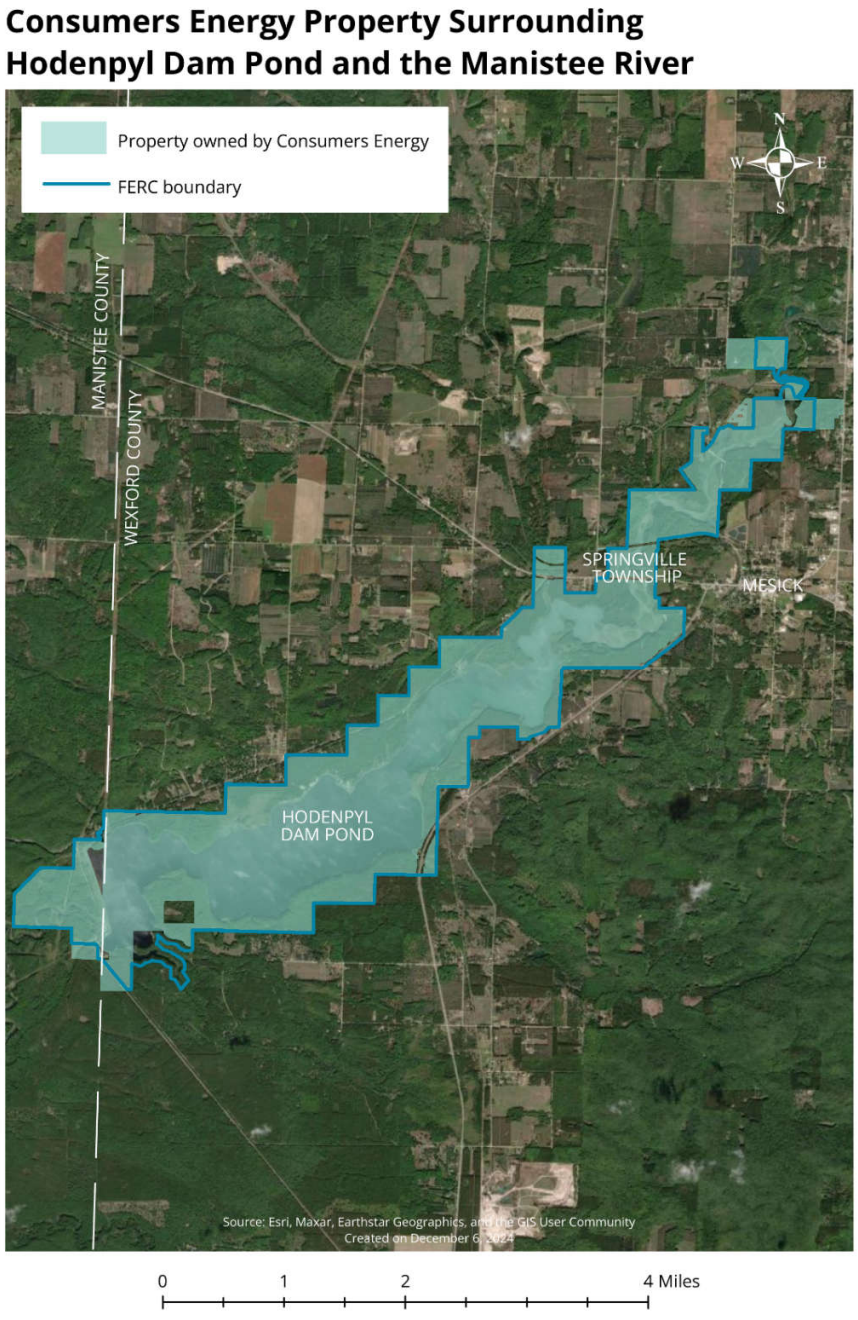
One prosperity group with two subgroups formed to discuss the river hydros on the Manistee River, the Hodenpyl Dam and the Tippy Dam. AES provided facilitation services to this group.

Hodenpyl Dam

Outdoor Recreation; Property Taxes and Revenue; Public Safety

The impoundment and river below the river hydro draw residents and visitors for a variety of outdoor recreation opportunities (e.g., camping, boating, fishing, hiking) and generates significant economic activity for the area. Across all three scenarios, group members prioritized **maintaining and improving those opportunities focusing on impoundment-based recreation** if the river hydro remains or a river-based recreation economy that incorporates open space and natural areas if the dam is removed. Exhibit 15 shows the location of Hardy Dam, the impoundment, and surrounding property owned by Consumers Energy.

Public safety in relation to maintenance of the river hydro and impoundment are another priority for the group. In a sale scenario, a new owner's ability to safely maintain the facility is a concern, so the group suggests a private owner be held to the same standards of regulation as Consumers Energy. Further, group members expressed concerns about whether a new owner will seek relicensing with FERC once the current license expires. In a decommissioning scenario, the safety concerns associated with a failure would be removed.



Local units of government and the school districts are supported, in part, by the property tax revenue they receive from Consumers Energy owning land along the impoundment and river. Group members prioritize **ensuring property tax and other revenue is maintained** under a relicensing scenario and a sale scenario. Under a decommissioning scenario, group members suggested **a shift in the tax base** could occur if previously submerged lands are sold to private entities or developed.

Representatives from these groups participated in the prosperity group:

- Alliance for Economic Success
- Cadillac Area Chamber of Commerce
- Cadillac Area Land Conservancy
- Cadillac Area Visitors Bureau
- Chris's RV Campground
- Conservation Resource Alliance
- Consumers Energy
- DNR Fisheries
- Great Lakes Fishery Commission
- Marilla Township
- Michigan Hydro Relicensing Coalition
- Michigan Trout Unlimited
- Northern Exposure Campground
- Pat's RV Park
- Residents and property owners

- Springville Township
- Wexford County
- Wexford County Road Commission

EXHIBIT 15. Consumers Energy Property Surrounding Hodenpyl Dam and Pond and the Manistee River

The Manistee River: Hodenpyl Dam prosperity group's priorities for the three scenarios, key actions to advance the priorities, and launch steps for those actions are presented in Exhibit 16.

EXHIBIT 16. Manistee River: Hodenpyl Dam Group Prosperity Plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Maintain dam safety and long-term viability of the dam and impoundment	Maintain Hodenpyl Dam according to Federal Energy Regulatory Commission (FERC) requirements	Consumers Energy meets with community emergency managers and communicate about safety measures and costs
	Continue stakeholder communications	Consumers Energy provides an annual public update about dam operations and events
Maintain and improve recreational opportunities including boating, fishing, birding, hunting and other impoundment recreational activities	Ensure additional resources are acquired to address climate changes	Consumers Energy seeks out federal and state grant funding addressing climate changes that will affect operations of the dam and surrounding impoundments
	Develop a recreational plan that includes more trails, more access points, additional trail signage, and expansive marketing for all forms of recreational activities	
	Continue monitoring river and impoundment water temperatures	Consumers Energy coordinates this with local community and government regulatory officials including United States Fish and Wildlife Service (USFWS) and the Michigan Department of Natural Resources (DNR)
	Continue to monitor and control invasive species	Consumers Energy helps initiate boat cleaning stations for managing invasive species in river and impoundment
Waterfront property ownership and leases remain unchanged	Protect current property values and business viability	Consumers Energy remains engaged in supporting property values and business viability
	Identify opportunities for local businesses to expand	Consumers Energy verifies ongoing property leases
Ensure property tax and other revenue is maintained to help support local units of government and schools	Maintain current FERC boundary	Consumers Energy considers options for private owners to retain or purchase properties

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Maintain safety and long-term viability of the dam and impoundment	Contract terms must address safe operations and long-term structural integrity of the dams	Consumers Energy should negotiate terms of sale for safe long-term operations and the longest possible power purchase agreement (PPA), even beyond 30 years
	Assure stakeholders that funding for dam maintenance and upgrades is covered in the PPA	Consumers Energy negotiates with buyer to implement bonds or other funding mechanisms for responsible and safe dam operation
	New owner must communication with and update community stakeholders regularly	Buyer should be directed to attend local government meetings periodically to update the community about dam operations and financials
Maintain and improve recreational opportunities including boating, fishing, birding, hunting and other impoundment recreational activities	Ensure that resources will be available to address impacts of climate changes	Consumers Energy encourages new owner to seek out federal and state grant funding addressing climate changes that will affect operations of the dams and surrounding impoundments
	Develop a recreational plan that includes more trails, more access points, additional trail signage, and expansive marketing for all forms of recreational activities	Consumers Energy negotiates with new owners to develop a recreational plan with input from environmental nonprofit organizations, Michigan Department of Environment, Great Lakes and Energy (EGLE), United States Forest Service (USFS), and local conservation groups
	Continue monitoring river and impoundment water temperatures	Consumers Energy coordinates this with local community and government regulatory officials including the USFWS and the DNR
	Continue communications with community stakeholders	Consumers Energy negotiates with new owners about how they will address community needs and provide information about ongoing recreational opportunities
	Continue to monitor and control invasive species	Purchase agreement should include provisions such as boat cleaning stations for managing invasive species in river and impoundment
Ensure that waterfront property ownership and leases remain unchanged and that private businesses can expand	Protect current property values and business viability	Buyer should develop a transition plan that fully addresses property values and business viability
	Maintain property lease agreements at least until 2034 and offer first right of refusal to current property leasers	Consumers Energy addresses this in negotiated PPA and sale agreement
Ensure property tax and other revenue is maintained to help support local units of government and schools	Ensure that energy efficiency credits don't drive new owner initiatives	Consumers Energy should address this in negotiated PPA and sale agreement
	FERC land should remain unchanged	Consumers Energy should address this in negotiated PPA and sale agreement

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Maintain large undeveloped parcels for diverse wildlife habitat and recreational use	Develop a recreation plan that includes opportunities to expand and link public trails and river access	Consumers Energy initiates development of a recreational plan task force that will include environmental nonprofit organizations, EGLE, USFS, local conservation groups, local government officials, and public and private stakeholders
	Study the river before the dams were built to identify new land emerging that can/should remain publicly accessible In addition, a field-based study of current conditions would be needed	Consumers Energy ensures that a decommissioning team of environmental engineers and associated public and private professionals is in place to conduct a formal field-based environmental study to describe the current river/impoundment environment and to recommend how re-emerging bottomlands should be integrated and managed This study should also include environmental impacts and recommendations if Tippy Dam is removed downriver
	Develop a habitat management plan to address recreation, land use, environment, and need for re-establishment of native plants	The formal field-based environmental study described above should include habitat management recommendations
Transition from impoundment-based activities to flowing river-based with increased year-round recreational opportunities	Ensure Americans with Disabilities Act (ADA) access in public campgrounds and other new recreation opportunities	The recreation plan referenced above should address ADA
	Develop a nature center associated with the upper Manistee state-recognized scenic river status and North Country Trail to increase traffic to this area and educate about the transition and impact on the ecology of the river system	The recreation plan referenced above should include recommendations on potential leadership and funding for development of a nature center
	Increase paddle sport access and expand all water-based recreational activities and opportunities	Consumers Energy, in conjunction with the recreational plan task force, will need to collaborate with area chambers and visitors bureaus, to conduct a data study comparing recreational opportunities and economic impacts before and after dam removal to determine increases/decreases and changes in recreational uses
	Explore funding opportunities for recreational enhancements and business transitions	The recreational task force including Consumers Energy and all associated conservation, recreational, environmental, economic development, government and chamber and visitors bureau entities will need to collaboratively explore all public and private funding opportunities for recreation and business development This group should also identify endowment funding opportunities through Consumers Energy—and potentially others—to support affected business owners during transition
	Market new opportunities broadly	Comprehensive marketing planning should be included in any recreational plans that are developed

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Assist affected businesses with transition from dam-based economy to river-flowing economy	Grants/loans will be needed to support businesses affected by the changes	Consumers Energy should consider providing economic remuneration during transition
	Transition to development of a business assistance network with broad-ranging resources	The above-referenced recreational plan task force should initiate collaboration with the Michigan Office of Rural Prosperity, Small Business Development Centers (SBDCs), area chambers of commerce and visitors bureaus, economic development organizations, and local governments to address financial needs of existing businesses
Maintain or increase property tax base	Study the amount of property that could be developed versus land left undeveloped for wildlife habitat and recreation Determine what portion of land needs to be private to maintain taxable value Ensure that floodplain will feature new grasslands and flora Conduct analysis of funding mechanisms	Consumers Energy initiates development of a post-dam property management planning committee including county and township representatives, private lease and campground owners, and others who are determined to be key stakeholders
	During transition, help existing businesses, schools, and municipalities that rely on this tax base for operations	Plans referenced above should address this and seek funding through Consumers Energy, State of Michigan, etc.
	Use proven and effective local zoning ordinances as a model	Property management planning committee should address this and define and clarify ownership options for land exposed after impoundment drains
Address environmental and infrastructure issues	Develop a habitat restoration plan, and ensure proper sedimentation stabilization	Need a cost analysis and commitment from Consumers Energy to restore habitat and address issues related to built-up sediment traveling downstream
	Ensure that invasive species concerns are addressed	The decommissioning team identified above should address invasive species mitigation Partners should include the Conservation Resource Alliance and other NPO stakeholders
	Develop a plan for the restoration of cold-water fisheries	Decommissioning planning should include Trout Unlimited, Michigan DNR Fisheries Division, Little River Band of Ottawa Indians, etc.
	Ensure that wildlife corridors remain when land use shifts	Include in above-referenced recreational and environmental management plans

Tippy Dam

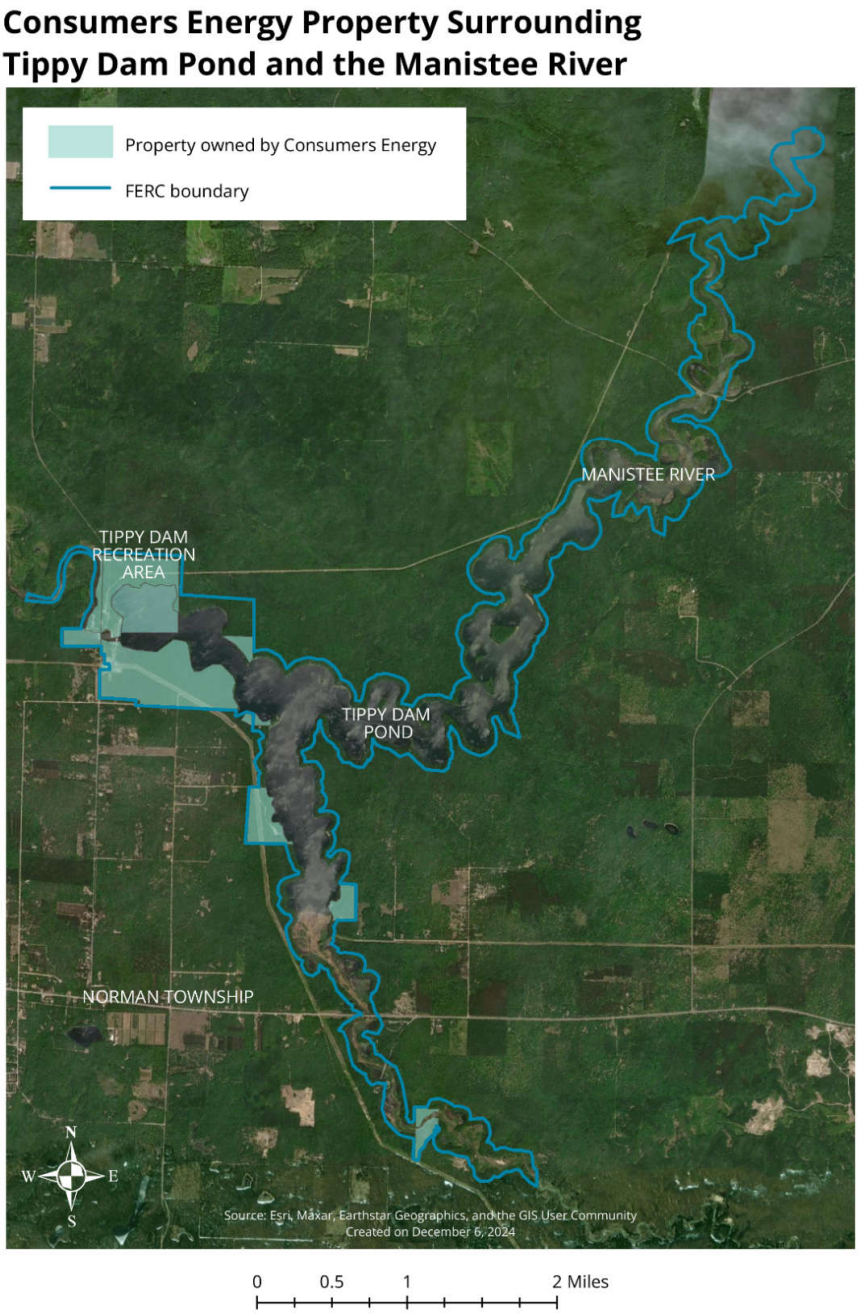
Outdoor Recreation; Habitat; Property Taxes and Revenue; Public Safety

A priority for the group is the maintenance of existing recreation assets as well as improving and expanding access to the river. **Connecting trails and developing nonmotorized river recreation** opportunities was identified across all three scenarios. In the event of decommissioning, members identified the need for a broader transition from impoundment-based activities to river-based activities with increased year-round opportunities. Exhibit 17 shows the location of Tippy Dam, the impoundment, and surrounding property owned by Consumers Energy.

The group identified the Manistee River fishery as a key asset to the region. River and impoundment water temp monitoring are essential while the river hydro remains. **Cold-water fishery restoration** was identified as a priority under a decommissioning scenario.

Wildlife habitat and unique species management was prioritized by the group in its vision of prosperity. Across all three scenarios, group members seek to **conserve large tracts of undeveloped land as wildlife habitat and corridors, accelerate research related to the bat hibernaculum, maintain a sea lamprey barrier, and continue lampricide treatment.** In event of a sale, they prioritize continued access to Tippy Dam to continue lampricide treatments and flow consistency.

Public safety in relation to maintenance of the river hydro and impoundment are another priority for the group. In a sale scenario, a new owner's ability to safely maintain the facility is a concern, so the group suggests a private owner be held to the same standards of regulation as Consumers Energy. Further, group members expressed concerns about whether a new owner will seek relicensing with FERC once the current license expires. In a decommissioning scenario, the safety concerns associated with a failure would be removed.



Local units of government and the school districts are supported, in part, by the property tax revenue they receive from Consumers Energy owning land along the impoundment and river. Group members support **ensuring property tax and other revenue is maintained** under a relicensing scenario and a sale scenario. Under a decommissioning scenario, group members suggested **a shift in the tax base** could occur if previously submerged lands are sold to private entities or developed. In addition, they envision developing a plan for growth by **increasing internet connectivity and building affordable housing units.**

Representatives from these groups participated in the prosperity group:

- Alliance for Economic Success
- Bear Lake Schools Districts
- Big Bear Sportsman's Club
- City of Manistee
- Conservation Resource Alliance
- Consumers Energy
- DNR Fisheries
- Great Lakes Fishery Commission
- Kaleva Norman Dickson Schools
- Little River Band of Ottawa Indians

- Loomis Landing Camping and Boating
- Manistee County Commission
- Manistee Economic Development Corporation
- Manistee Tourism Authority
- Maple Grove Township
- Michigan House of Representatives District 104
- Michigan Hydro Relicensing Coalition
- Michigan Trout Unlimited
- Norman Township
- Public Sector Consultants
- United Way of Manistee County

EXHIBIT 17. Consumers Energy Property Surrounding Tippy Dam and Pond and the Manistee River

The Manistee River: Tippy Dam prosperity group's priorities for the three scenarios, key actions to advance the priorities, and launch steps for those actions are presented in Exhibit 18.

EXHIBIT 18. Manistee River: Tippy Dam Group Prosperity Plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Maintain and grow recreational assets relative to diversity of waterways	Look at ways to improve and increase access to the river, including Americans with Disabilities Act (ADA) accessibility Increase access points on public-use land	Consumers Energy working with partners – State of Michigan, United States Forest Service (USFS), Little River Band of Ottawa Indians, etc.
	Address water temperature issue. Continue monitoring river and impoundment water temperatures	Consumers Energy in cooperation with partners like the Michigan Department of Natural Resources (DNR), United States Fish and Wildlife Service (USFWS), Trout Unlimited (TU), and others Increase tree planting for shade
	Improve access and parking at Red Bridge	Consumers Energy, DNR, other partners
	Improve Red Bridge boat launch with boat washing stations	Consumers Energy, DNR, other partners
Current wildlife habitat is unchanged, and the bat hibernaculum in the dam spillway remains	Accelerate research and increase funding related to bat hibernaculum	Continue to work with partner agencies, including the Ecological Services Program of the USFWS, and educational institutions to ensure healthy hibernaculum for bats
	Large tracks of undeveloped, public-use land are recognized and held as wildlife habitat and corridors	
Maintain dam safety and long-term viability	Consumers Energy will maintain their high safety standards	Partner with the Army Corp of Engineers Conduct routine safety inspections, drills, and exercises with partner agencies
	Consumers Energy will maintain the aging infrastructure according to Federal Energy Regulatory Commission (FERC) relicensing requirements	Consumers Energy and regulatory commission
Taxable values remain stable	FERC lands remain as is	
	Ownership of bottomlands needs to be identified	Consumers Energy / regulatory commission determine during relicensing
Sea lamprey barrier remains, also stopping other invasive species	Maintain sea lamprey mitigation system. Continue to provide access for lampricide treatment	Consumers Energy commits to providing access to partners for treatment and prevention of invasive species
	Tippy Dam is maintained as an effective barrier for other invasive species (invasive carp, etc.)	Consumers Energy maintains

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
	Put in boat cleaning stations at launch sites	Consumers Energy with partner agencies like DNR, USFWS, tribe, local invasive species prevention coalitions
	Work to control invasive species in Tippy Dam backwaters (e.g., zebra mussels and other invasives)	Consumers Energy with partner agencies like DNR, USFWS, tribe, local invasive species prevention coalitions

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Maintain and grow recreational assets relative to diversity of waterways	Access to the river must be maintained with new hydro facility ownership	Put provisions in the power purchase agreement (PPA) for maintenance and enhancements of existing access points (if included in sale)
	Need to address water temperature issue Continue to monitor river and impoundment water temperatures	New owners in cooperation with partners like DNR, USFWS, TU, and others Increase tree planting for shade
Current wildlife habitat is unchanged, and the bat hibernaculum in the dam spillway remains	Oversight for threatened species (bats) remains	Put provisions in the PPA for broad compliance with concerns
	Accelerate research and increase funding related to bat hibernaculum	Continue to work with partner agencies and educational institutions to ensure healthy hibernaculum for bats
	Large tracks of undeveloped, public-use land are recognized and held as wildlife habitat and corridors	
Taxable values remain stable	FERC lands remain as is	New owner keeps FERC land and pays taxes
	Large tracks of undeveloped, public-use land are recognized and held as wildlife habitat and corridors	

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Sea lamprey barrier remains, also stopping other invasive species	The dam is maintained as an effective barrier through the development of a memorandum of agreement (MOA) or memorandum of understanding (MOU) with the purchaser	MOA/MOU is a term of sale
	Continue to provide access to the dam after the sale to continue treatments and flow consistency	Work with partners agencies like TU, Great Lakes Fisheries Coalition, State of Michigan DNR Fisheries, etc.
Dam safety and long-term viability is maintained	Contract terms must address safe operations and long-term structural integrity of the dams	Consumers Energy should negotiate terms of sale for safe long-term operations and the longest possible PPA At a minimum, PPA should extend to end of license agreement
	PPA includes same/similar safety and maintenance requirements as current owner (Consumers Energy) for future owners	Regulatory commission with public input
	Financial (long-term) viability and assurances are required No shell companies	Consumers Energy does due diligence Regulatory agencies review
	Assure stakeholders that funding for dam maintenance and upgrades is covered in purchase agreement	Consumers Energy is responsible for communicating and assuring public of the long-term stability of the dam and subsequent maintenance and operations
	Ongoing stakeholder communication is important	Buyer is directed to attend local government meetings periodically to update about operations and financials

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Transition from impoundment-based activities to flowing river-based with increased year-round recreational opportunities	Put in place a four-season recreational trail system and river navigation plan with access sites and launches Increase connectivity across the river with pedestrian and recreational crossings Expanded ecotourism (fishing, hiking, paddling)	Consumers Energy initiates development of a recreational plan task force that will include Michigan Department of Environment, Great Lakes and Energy; USFS, conservation, tourism, and environmental groups; local government officials, and public and private stakeholders Funding through Michigan Natural Resources Trust Fund, Consumers Energy, etc.
	Develop a transition plan for businesses that will be forced to change and adapt to new river system Consider economic incentives	Consumers Energy to provide financial resources for transition. Grants/loans will be sought to support businesses affected by the change

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
	Develop a marketing plan to address new opportunities	Partner agencies (local stakeholders), funded through Consumers Energy, local, and other funding sources
The bat hibernaculum remains intact while research continues to discover why these bats are thriving	Accelerate research funding and testing for hibernacula	Consumers Energy continues to work with partner agencies and educational institutions to ensure healthy hibernaculum for bats
	Investigate option for leaving spillway intact to allow for river flow while maintaining bat hibernaculum	
Maintain or increase property tax base **Develop a master plan for land use of bottomlands and other areas no longer owned by Consumers Energy**	Study the amount of property that could be developed versus land left undeveloped for wildlife habitat and recreation Determine what portion of land needs to be private to maintain desired taxable value level Conduct analysis of funding mechanisms	Consumers Energy to initiate the development of a post-dam property management planning committee with township representatives and other local stakeholders Investigate ways to maintain large undeveloped wildlife corridors Use proven and effective local zoning ordinances as a model Plan must define and clarify ownership options for land exposed after impoundment drains
	During transition, provide monetary assistance to existing schools and municipalities that rely on this tax base for operations.	Plans should address this and seek funding through Consumers Energy, State of Michigan, etc.
Plan for growth: High-speed internet and new housing units	Increase connectivity to internet People are reluctant to move to an area with no connectivity	Consumers Energy leads efforts to plan with local, statewide, and regional partners to bring connectivity to rural areas Put pressure on county, local, and state government to find ways to make this affordable and priority for internet providers
	Build new (affordable) housing units to bring more people into the area	Consumers Energy continues to work with Housing North as an advocate and possible funder of housing development initiatives Investigate ways to increase housing capacity in rural areas of Manistee County
Create and build opportunities to increase wildlife habitat, fisheries, and invasive species barriers	Develop a habitat restoration plan Floodplain will feature new grasslands and flora	Need a cost analysis and commitment from Consumers Energy to restore habitat. Address issues related to built-up sediment traveling downstream
	Barrier to sea lamprey and other invasives must remain	Decommissioning plans should include barrier details, location, and terms defining responsibilities
	Ensure that wildlife corridors remain when land use shifts	Maintain undeveloped hunting and wildlife corridors

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
	Develop a plan that includes cold water fisheries Address the concern of nonnative fish moving upstream, competing with smaller native fish	Consumers Energy provides support for the creation of oversight committee Include resources to create natural features that help ensure cold-water stream Partners include TU, Michigan DNR Fisheries, Little River Band of Ottawa Indians, etc.

Muskegon River

One prosperity group with three subgroups formed to discuss the three river hydros on the Muskegon River: Rogers Dam; Hardy Dam; and Croton Dam. Omni Tech International provided facilitation services to this group.

Rogers Dam

Outdoor Recreation; Habitat; Property Owner Satisfaction; Public Safety

Maintaining and expanding outdoor recreation opportunities is a priority across all three scenarios. Regardless of the future of the dam, the group would like a **recreational master plan that prioritizes maintaining public access to the river/impoundment, adding additional canoe/kayak launch sites, and adding more trails and trail infrastructure.** In particular, the group wants to connect the river trail in Big Rapids to the Dragon Trail at Hardy Dam. The group would also like local governments to be enabled to manage and maintain both existing and future recreational sites, either through a land transfer or a legal agreement like a memorandum of understanding (MOU).

The group also agreed that quality wildlife habitat is essential to the prosperity of the region. **Maintaining the health of the fishery, protecting wildlife habitat (e.g., through conservation easements), and enhancing current habitat (e.g., by adding osprey towers and bat houses)** are priority actions that were identified across all three scenarios. If the dam is decommissioned, the group would like Consumers Energy to work with natural resource management organizations to identify and pursue opportunities for habitat enhancement as part of the dam removal process.

Property owner satisfaction is another priority for the group. **Frequent, accessible, transparent, and honest communication with property owners** will be important to maintaining property owner satisfaction regardless of the decision made. Additionally, especially in the event of dam removal, ensuring adjacent property owners continue to have water access would help maintain property owner satisfaction. Exhibit 19 shows the location of Rogers Dam, the impoundment, and surrounding property owned by Consumers Energy.

Finally, public safety was identified as a community priority. If the dam remains, either under ownership by Consumers Energy or another entity, the group wants to see **continuous upgrades and investments in dam safety measures.** If the dam is removed, a priority for the group is the development of a plan to **shift resources that are currently allocated to dam management/safety to river safety measures** (e.g., dive training for first responders).

Representatives from these groups participated in the prosperity group:

- City of Big Rapids
- Consumers Energy
- Big Rapids Public Schools
- Big Rapids Township
- Fremont Area Community Foundation
- Great Lakes Fishery Commission
- Homeowners association (HOA) representatives

- Mecosta County
- Mecosta County Parks
- Mecosta Township
- Michigan Hydro Relicensing Coalition
- Michigan Chapter of Trout Unlimited
- Muskegon River Watershed Assembly
- Newaygo County Road Commission/ Administration
- Office of State Representative Joseph Fox

EXHIBIT 19. Consumers Energy Property Surrounding Rogers Dam and Pond and the Muskegon River

The Muskegon River: Rogers Dam prosperity group's priorities for the three scenarios, key actions to advance the priorities, and launch steps for those actions are presented in Exhibit 20.

EXHIBIT 20. Muskegon River: Rogers Dam Group Prosperity Plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Continue to build upon current recreational assets to maintain and grow tourism and ensure that it remains as is or better	Maintain public recreational access at the dam site	Develop a recreational master plan that includes these priorities
	Add canoe launch on the west side of the dam	
	Add a nature center/pavilion near the river where community can gather and learn about the river, etc.	
	Connect the river trail in Big Rapids with the Dragon Trail at Hardy Dam	
	Enable local governments to manage the recreation sites	Land transfer/memorandum of understanding (MOU) between Consumers Energy and local governments
Ensure property values continue to hold their value	Maintain pond-based recreational opportunities	Ensure property owners continue to have recreational access
	Maintain aesthetic value of the pond	Consumers Energy protects water quality, removes trash, supports invasive species management
Ensure that the community does not have to worry about a long-term buyer plan	Maintain frequent and accessible communication with the community regarding dam operations and future plans	Hold public meetings Post more/better social media posts (especially on Facebook) Partner with local organizations to reach community members (e.g., through postcards)
	Be transparent and honest with the community	Send Consumers Energy representatives to local township meetings to answer questions/give updates; communicate timelines and deadlines and stick to them
Continue to maintain high satisfaction levels with property owners	Public engagement	Develop a public engagement strategy that includes public meetings; send mailers to ALL adjacent property owners to notify of meetings
	Maintain water levels satisfactory to property owners	
	Ensure safe operation of the dam	Continue to apply for grants and loans to support dam safety
Maintain/ improve current wildlife habitats	Add bird habitat (e.g., osprey towers)	Engage with the Michigan Department of Natural Resources (DNR) and Michigan Department of Environment, Great Lakes, and Energy (EGLE) for consultations to ensure best practices; seek funding to support habitat enhancement
	Add bat houses	
	Manage the sediment to ensure it does not negatively impact wildlife	

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
	Protect wildlife habitat in and around the dam	Enter into conservation easements with landowners
	Maintain the fishery's health	Engage consultants and experts in the field

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Continue to build upon current recreational assets to maintain and grow tourism and ensure that it remains as is or better	Maintain public recreational access at the dam site	Develop a recreational master plan that includes these priorities
	Add canoe launch on the west side of the dam	
	Add a nature center/pavilion near the river where community can gather and learn about the river, etc.	
	Connect the river trail in Big Rapids with the Dragon Trail at Hardy Dam	
	Enable local governments to manage the recreation sites	Negotiated as part of the sale agreement between Consumers Energy and the buyer
Ensure property values continue to hold their value	Maintain pond-based recreational opportunities	Ensure property owners continue to have recreational access
	Maintain aesthetic value of the pond	New owner protects water quality, removes trash and debris, supports invasive species management
Ensure that the community does not have to worry about a long-term buyer plan	Dam owner maintains frequent and accessible communication with the community regarding dam operations and future plans	Hold public meetings Post more/better social media posts (especially on Facebook) Partner with local organizations to reach community members (e.g., through postcards)
	New owner is transparent and honest with the community	Send representatives to local township meetings to answer questions/give updates Communicate timelines and deadlines and stick to them
	Share facts and data (especially financial) with community to help them understand reasons for ownership	Provide clear information about company background and intentions
Continue to maintain high satisfaction levels with property owners	Public engagement	Consumers Energy and new owner develop a public engagement strategy that includes public meetings
	Maintain water levels satisfactory to property owners	
	Ensure safe operation of the dam	Build funding for dam maintenance and upgrades into the power purchase agreement

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
	Provide assurance that the dam will not be sold in the next 30 years	Requirement of the sale agreement
Maintain/ improve current wildlife habitats	Add bird habitat (e.g., osprey towers)	Engage with DNR/EGLE for consultations to ensure best practices
	Add bat houses	
	Manage the sediment to ensure it does not negatively impact wildlife	Seek funding to support habitat enhancement
	Protect wildlife habitat in and around the impoundment	Enter into conservation easements with landowners; include provision in sale agreement that requires new owner to maintain habitat
	Maintain the fishery's health	Engage consultants and experts in the field

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key actions**	**Launch step**
Build upon the added recreational land, shifting tourism to more land and river-based activities	Provide local government land to develop new recreational facilities	Transfer Consumers Energy–owned parcels to local governments and/or negotiate management/maintenance MOUs with local governments
	Ensure/maintain public river access points	Develop a recreational master plan that includes these priorities
	Connect the river trail in Big Rapids with the Dragon Trail at Hardy Dam	
	Install ADA-accessible canoe/kayak launches on the west side of the river	
	Secure funding for design, engineering, and implementation of new recreational facilities	Consumers Energy helps local governments seek funding and also provides funding to support new recreational facilities
Develop a plan to shift management/ funding for dam emergencies to other opportunities	More training for government officials and first responders	Consumers Energy could provide/sponsor dive training and rope training opportunities
	Ensure access to river in case of emergency	Develop infrastructure (e.g., roads) and easements to allow emergency access
	Move/install fire hydrants	Work with local governments to determine how and where to locate fire hydrants
	Create a new river safety fund using monies that were previously allocated to dam safety	Consumers Energy creates fund

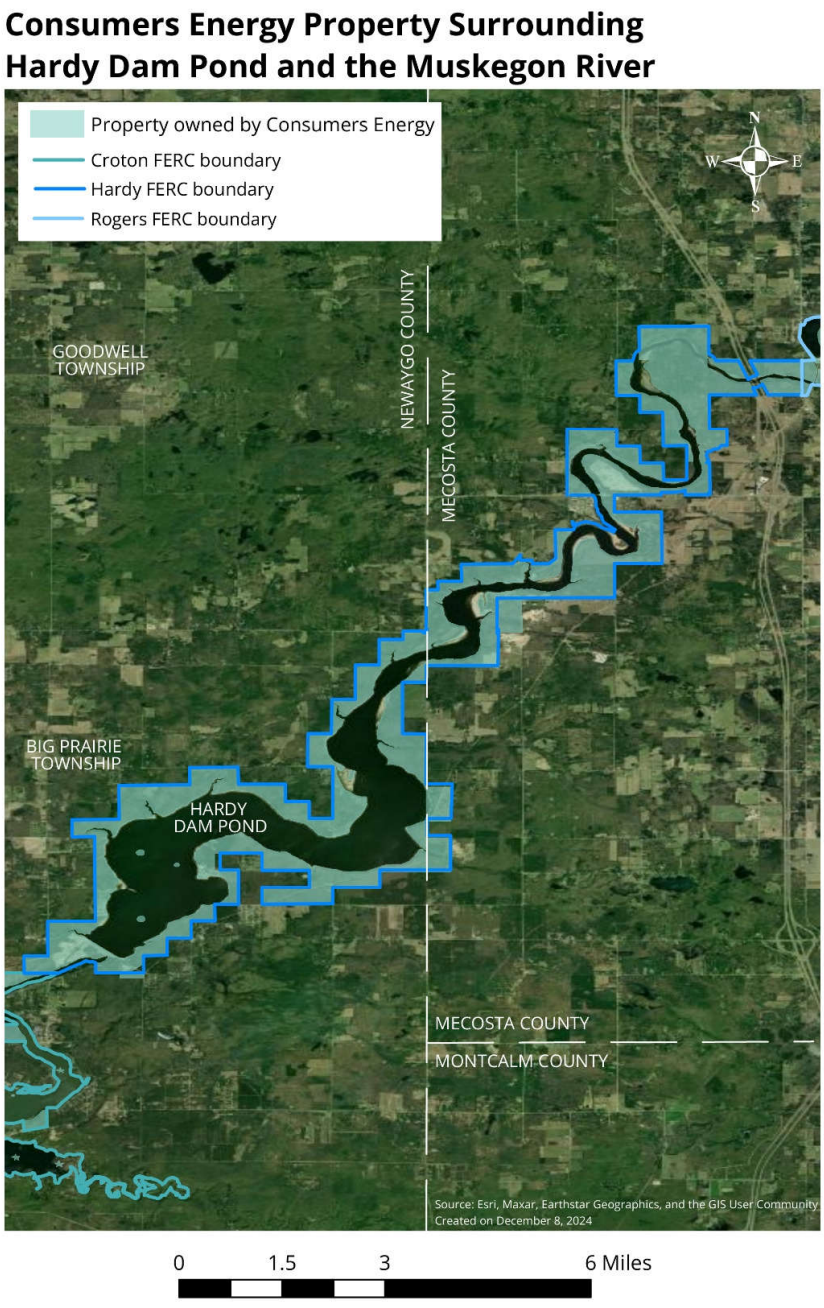
Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key actions**	**Launch step**
Develop a comprehensive plan for managing sediment	Share the sediment management plan with the community so they understand what to expect	Meet with the community during the development and implementation of the plan to answer questions and address concerns
	Remove toxins/contaminated sediment and dispose of safely	Conduct study to identify areas with contaminated sediment
Take actions to increase property owner satisfaction	Ensure property owners continue to have water access	Don't allow developer to buy currently undeveloped land; offer portions of bottomlands to owners for access
	Define property lines	Provide free legal advice for property owners regarding property boundaries
	Ensure safety of residents	Invest in river safety measures
	Prioritize open and transparent communication with property owners	Develop a comprehensive communication plan that ensures timely and transparent communication before, during, and after the dam removal process
Continue to create and build upon opportunities to increase nature-based tourism	Protect water quality	Work with local watershed organizations and other actors to implement water quality protection measures
	Explore opportunities to educate community about dam removal	Partner with educational institutions (e.g., Ferris State University, K–12 district) to develop curriculum and interpretive signage
	Enhance habitat for fish and other aquatic organisms	Work with natural resource management organizations to identify and pursue opportunities for habitat enhancement as part of the dam removal process
	Market and promote new recreational assets	Develop a marketing and promotion plan

Hardy Dam

Outdoor Recreation; Water Quality Improvement; Tourism

The Hardy Dam prosperity group identified outdoor recreation, water quality, and growing tourism/business opportunities among their top priorities for the community. Exhibit 21 shows the location of Hardy Dam, the impoundment, and surrounding property owned by Consumers Energy.

Maintaining and increasing outdoor recreation opportunities is a key priority identified by group members across all three scenarios. In particular, **continuing to maintain and develop the Dragon Trail and associated infrastructure** is important to the community. If the dam is sold, the group is concerned that a new owner will not honor existing lease/maintenance agreements; therefore, negotiating land transfers and/or establishing long-term leases to ensure the community is able to maintain current access to the Dragon Trail are primary priorities.



Achieving sustained water quality improvements is another priority articulated by the prosperity group. If the dam remains, either under Consumers Energy or some other entity's ownership, the group would like the owner to reevaluate dam operations with a focus on water quality improvement. This would necessitate consultations with engineers and specialists to identify and evaluate options for alternative dam management techniques. Similarly, if the dam is removed, water quality improvements and habitat restoration are top priorities for the community.

The remaining priorities focused on **growing tourism and becoming a destination community.** Group members prioritized partnering with community organizations to market and promote recreational activities and events and developing and executing a comprehensive marketing strategy across Newaygo and Mecosta Counties. If the dam is removed, **creating and implementing a redevelopment plan centered around land- and river-based recreation and tourism** is a top priority.

Representatives from these groups participated in the prosperity group:

- City of Big Rapids
- Consumers Energy
- Big Rapids Public Schools
- Big Rapids Township
- Fremont Area Community Foundation
- Great Lakes Fishery Commission
- Homeowners association (HOA) representatives
- Mecosta County
- Mecosta County Parks
- Mecosta Township
- Michigan Hydro Relicensing Coalition
- Michigan Chapter of Trout Unlimited
- Muskegon River Watershed Assembly
- Newaygo County Road Commission/ Administration
- Office of State Representative Joseph Fox

EXHIBIT 21. Consumers Energy Property Surrounding Hardy Dam and Pond and the Muskegon River

The Muskegon River: Hardy Dam prosperity group's priorities for the three scenarios, key actions to advance the priorities, and launch steps for those actions are presented in Exhibit 22.

EXHIBIT 22. Muskegon River: Hardy Dam Group Prosperity Plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Increase recreational opportunities and continue to develop Dragon Trail/trail head camp sites	Maintain existing lease agreements, keeping lease costs low	Consumers Energy maintains existing lease agreements
	Support grants for park infrastructure and improvement	Consumers Energy considers setting up a grants program for park infrastructure improvements that promote and expand recreational activities
	Improve portages	Consumers Energy supports design and installation of portages
	Continue to maintain undeveloped parcels	Consumers Energy supports maintenance of undeveloped parcels
Achieve sustained water quality improvements	Invest in operational changes to send cold water to Croton Dam Pond	Consumers Energy invests in operational changes to send cold water to Croton Dam Pond
	Reevaluate dam operations, with a focus on water quality improvement	Consumers drafts and agrees on new operational agreements Consultations with engineers/specialists to evaluate options for operational techniques that can be applied to help lower water temperatures
	Reevaluate dam operations, with a focus on water quality improvement	Reevaluate dam operations, with a focus on water quality improvement
Increase growth and stability of existing businesses, create new opportunities	Partner with community to market recreational activities/events	Consumers Energy offers support through sponsorships of events and volunteers
	Create marketing campaigns across Newaygo and Mecosta Counties	Newaygo and Mecosta Counties Tourism Councils create and execute a marketing strategy
	Maintain public access	Consumers Energy maintains all public easements
	Sell unrestricted property to public or private parties	Consumers Energy could consider sale of unrestricted property to public or private party
Expand efforts to become a destination community by focusing on real estate development and additional recreational opportunities	Provide more waterfront access and space to build, while protecting undeveloped land	Consumers Energy could consider selling a small percent of land for development with waterfront access and/or Consumers Energy could engage in long-term (>12 months) leases
	Promote hunting, biking, and other land-based recreational activities	Consumers Energy is a partner in promoting recreational opportunities

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
	Key Actions	**Launch Step**
Increase recreational opportunities and continue to develop Dragon Trail/trail head camp sites	Transfer land owned by Consumers Energy to county, townships, or other local bodies	Negotiated prior to license transfer
	Establish long-term lease agreements to foster community commitment, keeping lease costs low	New owner maintains existing lease agreements
	Restrict new owner to a percent of land for development	Negotiated as part of sale agreement
	Support grants for park infrastructure and improvement	Consumers Energy and/or new owner consider setting up a grants program for park infrastructure improvements that promote and expand recreational activities
	Continue to maintain undeveloped parcels	New owner supports maintenance of undeveloped parcels
Achieve sustained water quality improvements	Invest in operational changes to send cold water to Croton Dam Pond	New owner invests in operational changes to send cold water to Croton Dam Pond
	New owner establishes dam operational agreements, with a focus on water quality improvement	New owner drafts operational agreements Consultations with engineers/specialists to evaluate options for operational techniques that can be applied to help lower water temperatures
	Address algae bloom	New owner implements techniques that promote cold water mixing, reducing hot surface water
Increase growth and stability of existing businesses, create new opportunities	Partner with community in marketing recreational activities/events	New owner offers support through sponsorships of events and volunteers
	Create marketing campaigns across Newaygo and Mecosta Counties	Newaygo and Mecosta Counties Tourism Councils create and execute a marketing strategy
	Maintain all public easements and lease agreements	Consumers/New Owner ensure the Dragon Trail trailhead is deeded to counties
	Employment training for youth, preserving our environment (high school and college)	Consumers Energy could consider using a percentage of the sale proceeds to support an education fund for high school and college students job training or studying environmental preservation
Expand efforts to become a destination community by focusing on real estate development and additional recreational opportunities	Provide more waterfront access and space to build, while protecting undeveloped land	Consumers Energy/new owner could consider selling a small percent of land for development with waterfront access and/or could engage in long-term (>12 months) leases
	Promote hunting, biking, and other land-based recreational activities	Consumers Energy/new dam owner are partners in promoting recreational opportunities

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key Actions**	**Launch Step**
Maintain and expand recreational opportunities	Create recreational endowment fund to support projects such as a rustic camp area, expanded trail system, and ORV park/trail	Consumers Energy leads the creation of the fund
	Create a business development fund	Consumers Energy leads the creation of the fund
	Maintain undeveloped parcels	Consumers Energy supports maintenance of undeveloped parcels
	Local control to manage "new property" created during removal This includes but is not limited to assessments, surveying, and plotting of properties	Surveying costs supported by Consumers Energy
Restore cold water sturgeon fishery, fish migration	Develop a habitat restoration plan that includes restocking and long-term fish management	Consumers Energy pays for all costs as part of a planned dam removal process
	Activate sediment mitigation study	
	Address algae bloom	
Stability of existing businesses and creation of new opportunities	Create recreational endowment fund	Established by Consumers Energy prior to decommissioning
	Create a business development fund	Established by Consumers Energy prior to decommissioning
Rebrand the community as a destination community focused on nature/land appreciation	Add more waterfront access and space to build while protecting undeveloped land	Consumers Energy deeds land with waterfront access to counties
	Promote hunting, biking, and other land-based recreational activities	Consumers Energy is a partner in promoting redevelopment plan and economic funding
	Perform hazard assessment for impact of dam removal on infrastructure, homes, and businesses	Consumers Energy is financially responsible for reimbursement of assessment and impact costs

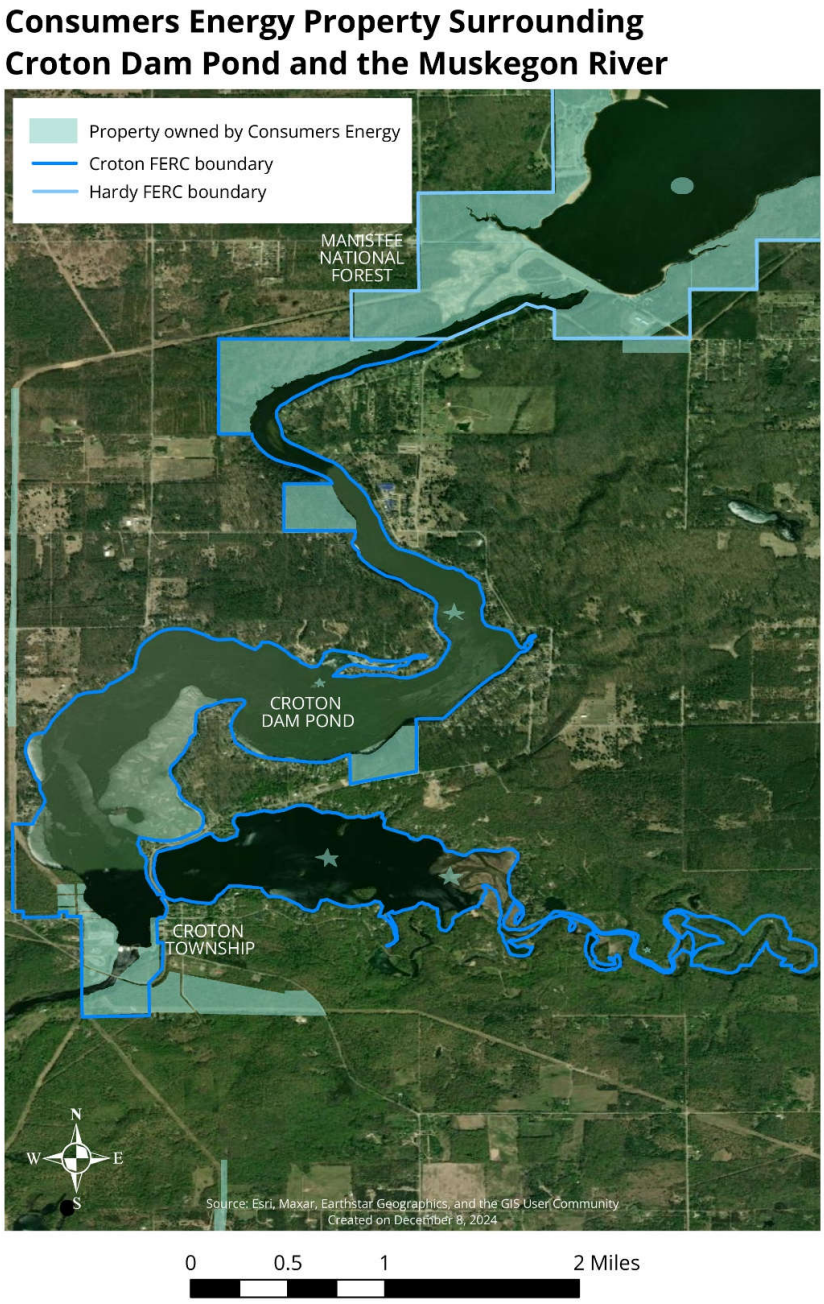
Croton Dam

Improving Water Quality; Habitat; Outdoor Recreation; Public Safety; Tourism Marketing

The Croton Dam prosperity group identified water quality and wildlife habitat, outdoor recreation, public safety, and tourism development among their top priorities for the community. Exhibit 23 shows the location of Croton Dam, the impoundment, and surrounding property owned by Consumers Energy.

Improving and enhancing water quality and wildlife habitat is a priority under all three scenarios. If the dam remains, investing in water quality improvement measures that would help **cool the water downstream, address algae blooms, and reduce the spread of invasive species like sea lamprey** are key priorities. If the dam is removed, maintaining a sea lamprey barrier is a key action identified by the group.

Further developing outdoor recreation opportunities is a clear priority for the prosperity group under all three scenarios. Enhancing and improving the quality and accessibility of the existing trail system and adding more canoe/kayak launches are key actions identified by the group. If the dam is removed, the community would like Consumers Energy to be a partner in developing a comprehensive transition plan that prioritizes adding more trails and expanding river-based recreational opportunities.



Public safety is a third priority articulated by the group. If the dam remains, sustained investments in dam safety will be critical to ensure community satisfaction. It was made apparent that the community has many concerns about a new owner as compared to continuing with Consumers as the owner. The community is worried that a new owner will not prioritize dam safety and will put the community in danger.

Finally, the group felt that marketing the area as a year-round tourism destination would help boost the community's prosperity. Developing a plan to **market and promote recreational and tourism opportunities** is a priority for the group. Depending on the decision made, the types of recreational opportunities promoted would vary (i.e., more pond-based activities vs. more river-based activities).

Representatives from these groups participated in the prosperity group:

- City of Big Rapids
- Consumers Energy
- Big Rapids Public Schools
- Big Rapids Township
- Fremont Area Community Foundation
- Great Lakes Fishery Commission
- Homeowners association (HOA) representatives
- Mecosta County
- Mecosta County Parks
- Mecosta Township
- Michigan Hydro Relicensing Coalition
- Michigan Chapter of Trout Unlimited
- Muskegon River Watershed Assembly
- Newaygo County Road Commission/ Administration
- Office of State Representative Joseph Fox

EXHIBIT 23. Consumers Energy Property Surrounding Croton Dam and Pond and the Muskegon River

The Muskegon River: Croton Dam prosperity group's priorities for the three scenarios, key actions to advance the priorities, and launch steps for those actions are presented in Exhibit 24.

EXHIBIT 24. Muskegon River: Croton Dam Group Prosperity Plan

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Further develop tourism and resident attractions (plan more events that draw in tourists; further develop trail system; improve tourism infrastructure)	Develop a comprehensive lake/watershed management plan to address and improve water quality issues - Identify solutions to cool the water downstream - Identify solutions to address algae blooms - Develop/implement a sediment management plan	Consumers Energy provides support for the development of the lake/watershed management plan - Support for new technologies to help cool the water downstream - Support to help develop the sediment management plan (subset of lake/watershed management plan)
	Enhance/improve the quality and accessibility of the existing trail system - Improve access to trails - Clearly identify and communicate land ownership - Expand/extend existing bike trail and improve overall quality - Enhance existing bridges (biking, walking, viewing site) for safety and accessibility	Consumers Energy helps maintain/improve access to trail system Consumers Energy should consider transitioning the land to public entity/providing financial support for land management - Form partnership for accessibility to trails (walking and biking) - Consumers Energy actively contributes information on ownership (e.g., signage reflecting ownership)
	Expand/market current and future recreational opportunities - Focus on campaign for quiet season - Market as a four-season destination - Expand marketing of events	Consumers Energy provides information/data and partners with local chambers of commerce / economic development organizations to increase messaging and marketing
	Improve accessibility to water activities - Install Americans with Disabilities Act (ADA) accessible kayak launches	Partnership with Consumers Energy and other entities to fund accessibility

Scenario One: Consumers Energy Seeks Relicensing		
Priority	**Key Actions**	**Launch Step**
Develop/ communicate a proactive decommissioning and community and economic transition plan	Develop a long-term full facilities lifecycle plan that includes maintenance and eventual decommissioning (comprehensive version of what is being done now)	Consumers Energy develops/communicates plan and updates regularly
	Establish monetary resources (e.g., a trust) to help with future community and economic transition	Consumers Energy should consider providing monetary supports

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
Further develop tourism and resident attractions (plan more events that draw in tourists, further develop trail system, improve tourism)	Develop a comprehensive lake/watershed management plan to address and improve water quality issues - Identify solutions to cool the water downstream - Identify solutions to address algae blooms - Develop/implement a sediment management plan	New owner provides support for the development of the lake/watershed management plan - Support for new technologies to help cool the water downstream - Support to help develop the sediment management plan (subset of lake/watershed management plan)
	Enhance/improve the quality and accessibility of the existing trail system - Improve access to trails - Clearly identify and communicate land ownership - Expand/extend existing bike trail and improve overall quality - Enhance existing bridges (biking, walking, viewing site) for safety and accessibility	Land transfer to public entity negotiated as part of sale New owner actively contributes information on ownership (e.g., signage reflecting ownership) New owner helps maintain/improve access to trail system - Form partnership for accessibility to trails (walking and biking) New owner considers providing financial support for land management
	Expand/market current and future opportunities - Focus on campaign for quiet season	New owner provides information/data and partners with local chambers of commerce /economic development organizations to increase messaging and marketing

Scenario Two: Consumers Energy Sells and Transfers the License to a New Owner		
Priority	**Key Actions**	**Launch Step**
	- Market as a four-season destination - Expand marketing of events	
	Improve accessibility to water activities - Install ADA-accessible kayak launches	Partnership with new owner and other entities to fund accessibility
Ensure that the sea lamprey barrier continues protecting upper watershed	Maintain current level of support of assets and accessibility (aesthetically pleasing dam, historical structure)	Consumers Energy negotiates with new owner to help support recreational assets and ensure boating boundaries, etc. New owner should consider creating a grant program for improvements
Ensure recreational access to Croton Pond remains for residents and the public	Address leased land issues with property owners (clearly identify scope of land ownership and ensure current landowners have the same access) Recreational/shared assets Lakefront/private ownership	Consumers Energy adds continued access to recreational assets as a condition of sale Transfer ownership of assets (lake front to homeowners, boat launch to public entity or neighborhood association)
	Enhance existing bridges and causeway (biking, walking, viewing site) for safety and accessibility	Support for recreational infrastructure improvements–could be provided by new owner and/or Consumers Energy
Maintain status quo (boating/ fishing, land values, public access, wetland habitats)	Maintain current level of support of assets and accessibility (aesthetically pleasing dam, historical structure)	Consumers Energy negotiates with new owner to help support recreational assets and ensure boating boundaries, etc. New owner should consider creating a grant program for improvements
Develop/ communicate a proactive decommissioning and community and economic transition plan	Develop a long-term plan and future resources (comprehensive version of what is being done now)	New owner develops/ communicates plan and updates regularly Consumers Energy should consider providing supports for new owner in development of plan
	Establish monetary resources (e.g., a trust) to help with future community and economic transition	Consumers Energy/new owner should consider providing monetary supports

Scenario Three: Consumers Energy Decommissions the Dam and the River Is Free Flowing		
Priority	**Key actions**	**Launch step**
Develop plans to recapture and shift resources/time currently spent on dam safety	Develop a sediment management plan	Consumers Energy provides resources and data, develops the plans, and sets up regular comprehensive communication sessions with the community
	Identify and communicate downstream benefits and impacts of dam removal	
	Develop a decommission timeline plan with access to decommission reports/data	
	Clear communication to community on timeline	
	Develop a plan to address sea lamprey	Consumers Energy works with the Great Lakes Fishery Commission and U.S. Fish and Wildlife Service to conduct sea lamprey barrier feasibility studies
Develop an area wide land use plan and opportunities for property expansion (extension of property under former pond)	Maintain waterfront access for owners; transfer property rights to homeowners	Consumers Energy transfers property rights to property owners
	Identify current legal rights of adjacent property	Consumers Energy investigates as part of decommissioning process
	Give community choice for trail expansion; explore option to grant easements for owners	Consumers Energy helps with land use plan/study, including community input on trail expansion options Put plan agreements in place for any options identified; identify if agreements are coordinated by city, county, or some other entity
	Address bottomland ownership issues	Consumers Energy investigates
Build/expand new recreational opportunities (cold water fishery expansion, full river habitat restoration, trail improvement)	Develop a river restoration plan	Consumers Energy provides support for a river management plan that prioritizes river restoration
	Review/improve access points to river	Financial support for access point changes–could be provided by Consumers Energy
	Expand access to paddle sports	Economic development support; equipment purchases
	Develop a coordination plan for where the Little Muskegon River comes into the Muskegon River (water flow, temperature, etc.)	Consumers Energy supports plan development
	Maintain sea lamprey barriers	Support for long-term plan to maintain sea lamprey barriers
Develop/expand new economic drivers and real estate development (as a riverfront asset)	Expand marketing plan for recreational uses (fishing tours, different types of anglers, etc.)	Consumers Energy could provide financial support to develop the plan Consumers Energy could provide grants to recreational business owners
	Provide economic support for businesses to transition	Consumers Energy should consider providing land/opportunities for businesses to expand
	Create a boardwalk	Support for a land use plan; consultants and expertise
	Create a birdwatching station	Financial support–could be provided by Consumers Energy
