New Lansing Service Center – Potential Locations within City of Lansing

401 N. Verlinden Ave. Lansing, MI 48915

Positives:
- Low purchase price
- Potential tax incentives available
- Utilities available

Limitations:
- Environmental concerns
- Unknown abandon utilities and tunnels under surface
- LBWL substation on site along with HVD line but unable to serve ourselves with electric
- Fiber would need to be ran to site
- Medium-risk security assessment needed

S. Waverly Rd. & W. Miller Rd. Lansing, MI 48911

Positives:
- Potential assistance with site preparation
- Potential assistance with demo of asbestos

Limitations:
- Wetlands and possibly not enough usable property
- Potentially unable to have a drive on S. Waverly due to hill and high speeds coming northbound on Waverly - both drives would have to be off of W. Miller Rd
- Length of time to potentially acquire site
- Demo of houses with asbestos
- Probably unable to serve ourselves with electric
- Fiber is currently some distance away – would need to be ran to site
- Currently zoned residential and would need to be rezoned to light industrial
- Medium-risk security assessment needed
- Unknown purchase price

New Lansing Service Center – Potential Locations within City of Lansing

South of Grand River, Ave.

Positives:

- Utilities available (Water & Sewer)

Limitations:

- Fuel station across the street
- Possible wetlands
- Further north
- Lots of traffic on road

*No other data was collected regarding this location

New Lansing Service Center Potential Location

401 N. Verlinden Ave. Lansing - Site Characteristics

57 acres

Response Time:	• 87% of reported outages are reached in 30 minutes timeframe • 100% of reported outages are reached within 45 minutes
Ease of Travel:	CE Operations: • Difficulty with turning and maneuvering trucks and trailers through city streets and blocks • Travel impediment due to foot and bike traffic, CATA bus stops, railroad crossing and street parking in residential areas • Difficult to access highways through residential areas: 2 miles to I-496
Security:	• **CE Security Risk Assessment Rating – HIGH** • Crimes occurring within 1-mile radius of parcel within 12/26/19-01/23/20: Assault – 15; Weapon Offenses – 6; Larceny – 6; Vandalism – 4; Burglary – 4; Motor Vehicle Theft – 3; Robbery – 1 • 74 sex offenders in registry within 1-mile radius
Wetlands identified:	• No identified wetlands on the parcel
Environmental concerns:	• Significant concern regarding existing contamination and abandoned underground utility facilities on the property. Further due diligence would be required if site is selected to evaluate impact to service center construction and operations.

New Lansing Service Center Potential Location

S. Waverly & W. Miller Rd, Lansing - Site Characteristics

33 usable acres

Response Time:	• 88% of reported outages are reached in the 30 minutes • 100% of reported outages are reached within 50 minutes
Ease of Travel:	CE Operations: • Difficulty with turning and maneuvering trucks and trailers through city streets and blocks • Travel impediment due to foot and bike traffic, CATA bus stops and street parking in residential areas • Difficult to access highways through residential areas: 1.5 miles to I-96
Security:	• **CE Security Risk Assessment Rating – MEDIUM** • Crimes occurring within 1-mile radius of parcel within 12/26/19-01/23/20: Assault – 6; Vandalism – 1; Larceny – 1; Motor Vehicle Theft – 1 • 16 sex offenders in registry within 1-mile radius
Wetlands identified:	• The State's National Wetland Inventory map indicates 17 acres of regulated wetlands of the 50-acre parcel • CE would not be able to use 17 acres without costly wetland mitigation. Would limit or possibly eliminate future expansion on site.
Environmental concerns:	• LEAP reports asbestos abatement needed prior to demolition of existing houses on parcel • CE Environmental reports existing contaminated site on the adjacent property to the east

New Lansing Service Center Potential Location

6964 N. Canal Rd, Dimondale - Site Characteristics

60 usable acres

Response Time:	• 91% of reported outages are reached in the 30 minute timeframe • 100% of reported outages are reached within 45 minutes
Ease of Travel:	CE Operations: • Located in the industrial area of Windsor Commerce Parkway. Roads and intersections provide for wider turns for maneuvering trucks and trailers • Access to highways through commercial areas: 0.75 miles to I-96; 1.35 miles to I-69 • Limited foot and bike traffic and no parking on roads
Security:	• **CE Security Risk Assessment Rating – LOW** • Crimes occurring within 1-mile radius of parcel within 12/26/19-01/23/20: Assault – 0 • 4 sex offenders in registry within 1-mile radius • High police presence due to Michigan State Police within 0.6 miles from parcel
Wetlands identified:	• The State's National Wetland Inventory map indicates 7.29 acres of regulated wetlands on the 77.67-acre parcel • Property size allows for CE use to be designed to avoid wetland areas and allow for future expansion.
Environmental concerns:	• No known environmental concerns

Gas Call Drive Time Summary

- **For the current Hastings Service Center and the proposed site at Vacant Land M-179**
  - Within 20 minutes we are able to reach 50% of gas customers and in 40 minutes we are able to reach 100% of gas customers.
- **For the proposed site at Vacant Land Enterprise Drive**
  - Within 25 minutes we are able to reach 50% of gas customers and in 45 minutes we are able to reach 100% of gas customers.

Electric Outage Drive Time Summary

- **For the current Hastings Service Center and the proposed site at Vacant Land M-179**
  - Within 15 minutes we are able to reach 50% of electric customers and in 30 minutes we are able to reach 100% of electric customers.
- **For the proposed site at Vacant Land Enterprise Drive**
  - Within 20 minutes we are able to reach 50% of electric customers and in 30 minutes we are able to reach 100% of electric customers.

Summary Site Comparison

Vacant Land: Enterprise Dr

- Public water and septic
- Would add 5 minutes to both electric and gas drive times

Vacant Land: M-179

- Private water and septic
- Drive times would remain similar to what is being experienced at the current location

Hastings Service Center Site Options Comparison

Vacant Land: Enterprise Dr, Hastings, MI 49058

Characteristics:

- Property – 18 acres
- Municipal Water – Available at the street
- Municipal Sewer – Available at the street
- Fiber – Available
- Wetlands – No mitigation required
- 3-Phase – Available at the street
- Natural Gas – Available at the street

Vacant Land: M-179, Hastings, MI 49058

Characteristics:

- Property – 30 Acres
- Private Water System – New system needed
- Private Septic System – New system needed
- Fiber – Available
- Wetlands – No mitigation required
- 3-Phase – Available at the street
- Natural Gas – Available at the street

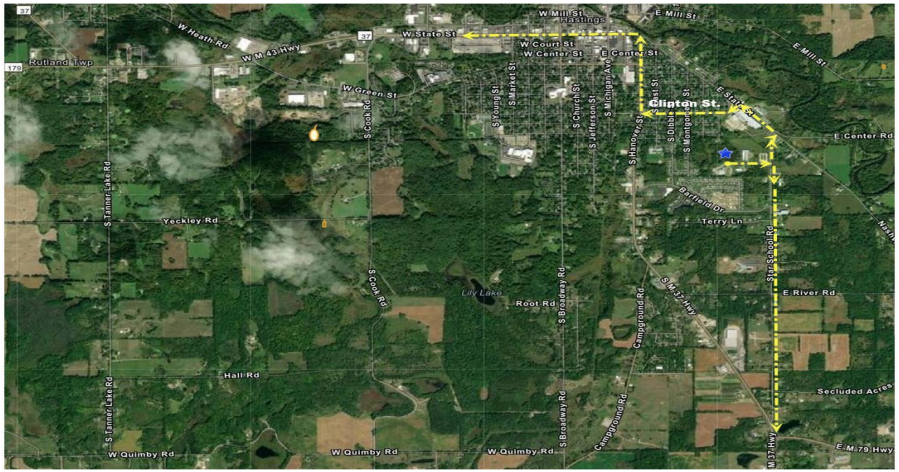
Vacant Land: M-179, Hastings, MI 49058

Location Description: Just west of the corner of M-43 and M-37, on M-179 at M-43. Just East of Kellogg Community College parcel.

Access: Main entrance off M-37

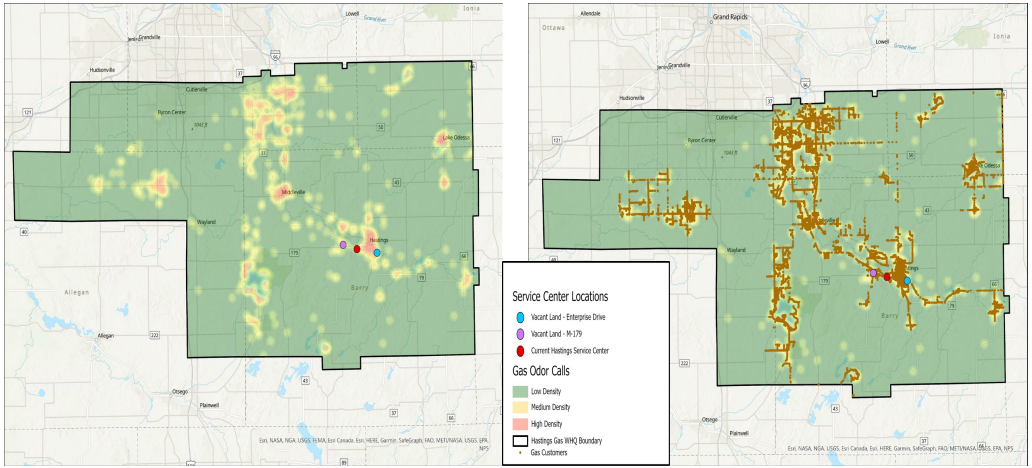
Owner: 2 property owners have been approached one being Kellogg Community College

Vacant Land: Enterprise Dr, Hastings, MI 49058

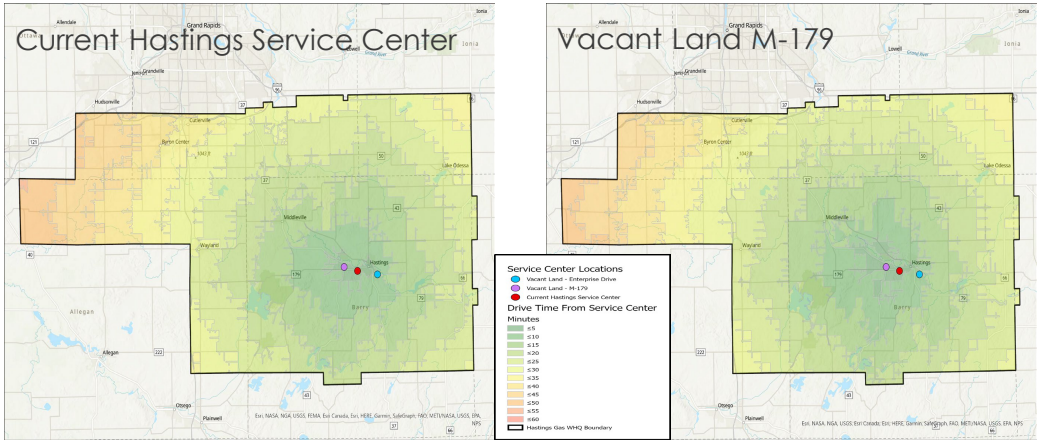


Location Description: Southeast in the City just off E State St and Star School Rd in the Industrial Park

Access: There could be multiple drives on E. Enterprise Dr. Northeast parcel has access to Star School Rd.



Owner: City of Hastings, parcels are currently for sale.



Class A Road Access Vacant Land Enterprise Dr.

Proposed New East Kent Facility

- Current Sale Offer: $5.2 million
- 4501 40th Street S.E., Kentwood, MI 49512
- Adjacent to existing Company property (Plaster Creek Electric Substation – 53 acres).
- 3.8 acres with adjoining acreage from Company property and secondary entrance from Plaster Creek Electric Substation access
- Building footprint (40,660 FT2)
- Second story office (5,520 FT2)
- Mezzanine (7,176 FT2)

Impact of Reduced Fleet Purchases

Implications for Cost, Safety, and Reliability (2016–2025)

Purpose and Context

This paper is an analysis based on the Attorney General's recommendation that:

> "The Commission direct the Company to present a thorough plan in the Electric Rate Case that addresses the utilization rate of vehicles and field equipment and the impact of reduced vehicle purchases in future years."

The Company fleet data analyzed (found in Exhibit A-148 (JJJ-7) focused on owned fleet, excluding rental assets that are typically newer, more temporary units. This view is essential for understanding the true long-term fleet status because owned assets carry the full burden of vehicle lifespan cost, safety risk, and reliability exposure. Unlike rentals, owned assets remain on the balance sheet longer, accumulate wear and tear, and require increasing internal maintenance resources as they age. The wear and tear over time may also contribute to higher vigilance to key safety equipment and apparatus, and higher fossil fuel emissions and consumption.

This analysis examines Company fleet data and how the owned fleet has aged over the 2016–2025 period and explains why the aging trend shown in the data is a risk that requires a plan to stabilize fleet aging. The focus on aging is critical as it relates to "reduced vehicle purchases in future years". There is a direct relationship between the number of vehicles purchased, and the direct impact it has on the age of the fleet. Holding on to units that are past the point of their

replacement cycle will continue to progressively age the fleet. This forces the continued use of older units, with the associated challenges of keeping older units safe, functional, and cost effective even as they continue to be utilized.

Further, this analysis contends that the impact of reduced vehicle purchases in future years would be detrimental to the Company's overall fleet. There are potential significant financial, operational, and safety considerations for the Company that must be managed, concluding that reduced vehicle fleet purchases in future years would have a negative impact on the Company's ability to provide safe, reliable, and efficient services to its customers. Lastly, even as unit age increases, average utilization rates over the study period rise or stay stable despite the aging of the fleet, indicating that the Company is extracting more work from an older fleet.

Quantitative Overview of Fleet Aging

The Company's fleet, not including rentals, shows that the average age of the owned fleet ages as follows:

- **2016:** 9.72 years
- **2017:** 9.32 years
- **2018:** 9.26 years
- **2019:** 9.36 years
- **2020:** 9.19 years
- **2021:** 9.30 years
- **2022:** 7.82 years
- **2023:** 8.15 years
- **2024:** 8.40 years
- **2025:** 8.89 years

Fleet Age Trends Higher

- The fleet entered the study period, already very mature, averaging close to 10 years old.
- A temporary reduction in age in 2022 interrupts the trend.
- From 2023 onward, average age rises every year, reaching 8.9 years by 2025.
- The long-term direction is upward, not stable, or declining.

The data shows that based on the current fleet purchase plan the owned fleet is already aging based on current spend levels, averaging about 4.4% per year increase in average age between 2022 and 2025. The current replacement rate has not been sufficient to reverse this trend. It should be noted that the data shows a sharp reduction in average age from 9.30 years in 2021 to 7.82 years in 2022. At first glance, this could be interpreted as a refresh of the fleet. However, while new vehicles were purchased during this period, the disallowance of those purchases resulted in the disposition of many of those new units. Therefore, the influence of newer vehicles on the overall age of the fleet was temporary.

- The reduction in fleet age coincides with a decline in total owned units, indicating removals or disallowance rather than sustained over-replacement.
- Average age could have remained stable in the subsequent years if disallowed units remained in the fleet.
- Average fleet age rises steadily from 2022 through 2025, regaining more than one full year of age in just three cycles.

This pattern indicates that the 2022 reduction in overall aging trend was an anomaly driven by one-time actions, not by an ongoing replacement strategy that keeps a more sustainable mix of vehicle lifecycles.

Long-Term Aging Trend of the Fleet

When rentals are excluded, the aging rate is concerning:

- In seven out of 10 years, the owned fleet averages above 9 years.
- Even after the 2022 reduction, the fleet quickly rebounds toward that level.
- By 2025, the owned fleet is once again approaching 9 years average age, placing a sizable portion of assets well beyond midlife.

Drivers of Aging

1. **Historical Spend**
   The current Fleet Replacement Plan is limited to the currently approved historical plus inflation budget.
2. **Replacement Lag**
   Annual acquisitions are insufficient to offset natural aging of the installed base. Production units take about two years from order to delivery.
3. **Long-Lived Asset Classes**
   Even accounting for specialty equipment, shop units that remain in service longer than a typical light-duty asset, there is an aging trend for critical production units like bucket and pick-up trucks.

Impact on Fleet Cost

Rising Maintenance and Repair Costs

As assets age, maintenance costs can increase non-linearly. Older equipment often requires:

- More frequent preventive maintenance.
- Higher corrective maintenance due to part failures.
- Longer shop visits and higher labor hours per event.
- Potential delays as parts for older vehicles may become obsolete.

With an average age of nearly 9 years, a sizable portion of the owned fleet will cost more to maintain as they approach the end of their lifecycle.

Even if annual maintenance budgets appear stable, cost per unit inevitably increases because:

- Parts availability declines for older models potentially delaying repairs or increasing the cost of the parts.
- Mechanic's labor hours rise.
- Planned maintenance is supplemented by unplanned repairs.

The data for Company owned vehicles strongly suggests that maintenance cost pressure is inherent in the purchase plan and growing, not a short-term concern.

Fleet Purchase Plan Limitations

The effect of the current fleet replacement plan does not allow the Company to keep pace with the number of vehicles that are approaching or have reached their end of lifecycle. The result can mean increased operating expenses over time to keep older vehicles safe and operational even as their utilization continues. The risk of increased exposure to large, unplanned repair events and cost increases associated with older vehicles and equipment rises. The steady rise in average age from 2023 to 2025 indicates that the organization is accumulating future capital risk, even if annual budgets stay consistent.

Increasing Total Cost of Ownership

As fleet age increases:

- Depreciation of efficiency declines.
- Maintenance costs per mile/hour rise.
- Downtime-related costs (lost productivity, backup equipment) increase.

- Potential for unpredictable repairs rise (e.g. in field breakdowns)

The cost data for Company many owned vehicles and equipment shows that the owned fleet spends extended time beyond optimal economic life, highlighted by the costs associated with maintaining some units as they approach the 8 to 10 years in service range.

Impact on Reliability

Reliability deteriorates as assets age due to:

- Component fatigue (chassis and body degradation).
- Unpredictable parts failures (e.g. belts, hoses, transmission failures etc.)
- Obsolescence of electronics and controls.

With average age hovering near 9 years, a growing share of the owned fleet is statistically more likely to experience:

- Breakdown events.
- Safety related concerns.
- Major component failures including engine, transmission, boom, and upfit equipment.
- Cascading component damage.

This raises not only maintenance costs, but also potential serious operational disruptions. For example, in February 2026, there was a catastrophic boom tip failure occurring on a 2015 Terex TL-55 bucket truck in Flint. The deployed bucket, with two men in it, partially detached and overturned, suspending the linemen in mid-air attached to their safety tethers. At the time of the incident, the truck in question was 11 years old, had reached the Blended Factor threshold for replacement, and was already planned for replacement in 2026.

Downtime and Availability Risk

Older fleets tend to experience:

- Longer repair-cycle times.
- Increased parts back-order delays for increasingly hard to find parts.
- Reduced interchangeability with newer systems.

From an operational standpoint, aging reduces asset availability, with a higher probability of unpredictable emergent repairs that can occur between preventative maintenance schedules. This includes engine and transmission failure replacements that can bring older units down, and increases reliance on:

- Spare units
- Short-term rentals

The fact that this analysis excludes rentals makes the reliability warning even stronger: the core fleet is aging, forcing the Company to rely on deploying its workforce in aging critical units that are experiencing increasing wear and tear, reliability and safety concerns, and rising maintenance costs during a critical period in infrastructure improvement planning in addition to ongoing storm restorations.

Reliability Variability Across Units

As age distribution widens, reliability becomes:

- Less predictable: increasing odds of in the field breakdowns or failures.
- More dependent on unit-by-unit condition inspections.
- More difficult to manage through standardized maintenance programs.

This variability strains planning, scheduling, and shop workload.

Impact on Safety & Mechanical Safety Risk

Aging equipment increases the likelihood of:

- Brake systems degradation.
- Steering and suspension failures.
- Hydraulic or electrical system faults.
- Body, upfit, frame and sub-frame corrosion.

Even with rigorous regular (preventative maintenance) inspections, older equipment has narrower safety margins due to cumulative wear. The aging trends shown by the data imply the potential for increasing number of assets that are operating (or will operate) closer to minimum acceptable condition, which is not optimal for the safety conditions to serve customers or for the safety of the Company's crews.

Technology Obsolescence

Older owned assets often lack:

- Improved modern safety features that newer vehicles offer.
- Advanced diagnostics.
- Electronic stability or operator-aid systems Advanced Driver-Assistance Systems (known as ADAS) that are becoming increasingly available in vehicles even with commercial fleet specifications.

As the average age increases, the fleet becomes less aligned with current safety standards, even if it remains legally compliant. This increases organizational exposure to:

- Injury risk.
- Incident severity.
- Liability and reputational impact from the Company's workforce.

Human-Factor Risk

Older equipment:

- Requires more manual intervention.
- Usually, they have less ergonomic designs or have worn components like driver seats.
- Creates higher operator workload during failure, or delays in scheduling as malfunctioning vehicles require moving crews into spares when available.

These factors elevate the risk of operator error and fatigue-related incidents, particularly during breakdowns or emergency situations.

The workforce expects that the Company will provide fleet units that are safe and reliable tools engaged to perform the work required, often under challenging situations and conditions, especially during storm restoration.

Operational and Strategic Consequences

When fleet aging is gradual, organizations often defer action. However, once enough assets approach end-of-life simultaneously, replacement decisions can shift from strategic to reactive. This can result in:

- Compressed capital funding needs
- Reduced procurement leverage
- Higher per-unit acquisition cost

The upward trend after 2022 serves as a signal that future replacement challenges are developing.

Strategic Implications and Takeaways

Key Conclusions

1. The owned fleet is inherently aging, not temporarily fluctuating.
2. Aging directly increases cost, downtime, safety exposure, and reliability risk.
3. Current rate of 1:1 replacement cannot keep pace with fleet aging trends.
4. Without intentional intervention, fleet's average age will continue trending upward.

Final Assessment

The Company's fleet data suggests that the fleet is on course to continue aging at current level of spending. Planning for a systematic future reduction of fleet purchases would have a detrimental impact on fleet's ability to support Reliability Work Plan projects that will require a robust fleet for the grid enhancements planned over the next decade. Additionally, the average utilization data suggests that vehicles continue to be used despite being in the latter stages of their lifespans. There is a sizable portion of the Company's fleet that is at or nearly past its optimal point. Since the current underlying trend shows that replacement levels are insufficient to counteract natural aging, it would not be prudent to plan any significant *reduction* in total units. In fact, it is the opposite, fleet should be planning to *lower the average age* of critical production vehicles, like service bucket trucks, which have long lead times of one and a half to two years to build. Delaying the replacement of older bucket trucks could exacerbate the overall aging for these units as the Company waits for their replacements to be delivered.

Left unaddressed, this trajectory will result in:

- Escalating maintenance cost.
- Increased unplanned downtime due to worn engines, transmissions, etc.

- Higher safety and liability exposure such as the recent boom tip failure.
- Larger, more disruptive unplanned capital requirements in the future.

From a fleet management perspective, the data supports a shift toward an accelerated, multi-year, expanded 1:1 replacement planning process, designed to replace old units that intentionally reduce overall average fleet age.

Regarding the correlation between reduced fleet purchases and utilization rates, the data suggests that even as key fleet assets age, their utilization actually rises over the study period, like specs 64, 89, and 96 bucket trucks for example. Lowering fleet purchases for this group would actually exacerbate fleet aging and increase maintenance costs as the Company would rely even more on an aging fleet. Therefore, it is the conclusion of this analysis that it would not be prudent to intentionally *reduce* fleet purchases in the future as its impact on the electric and gas services, grid improvements and storm restoration work the Company provides customers may be compromised in future years.

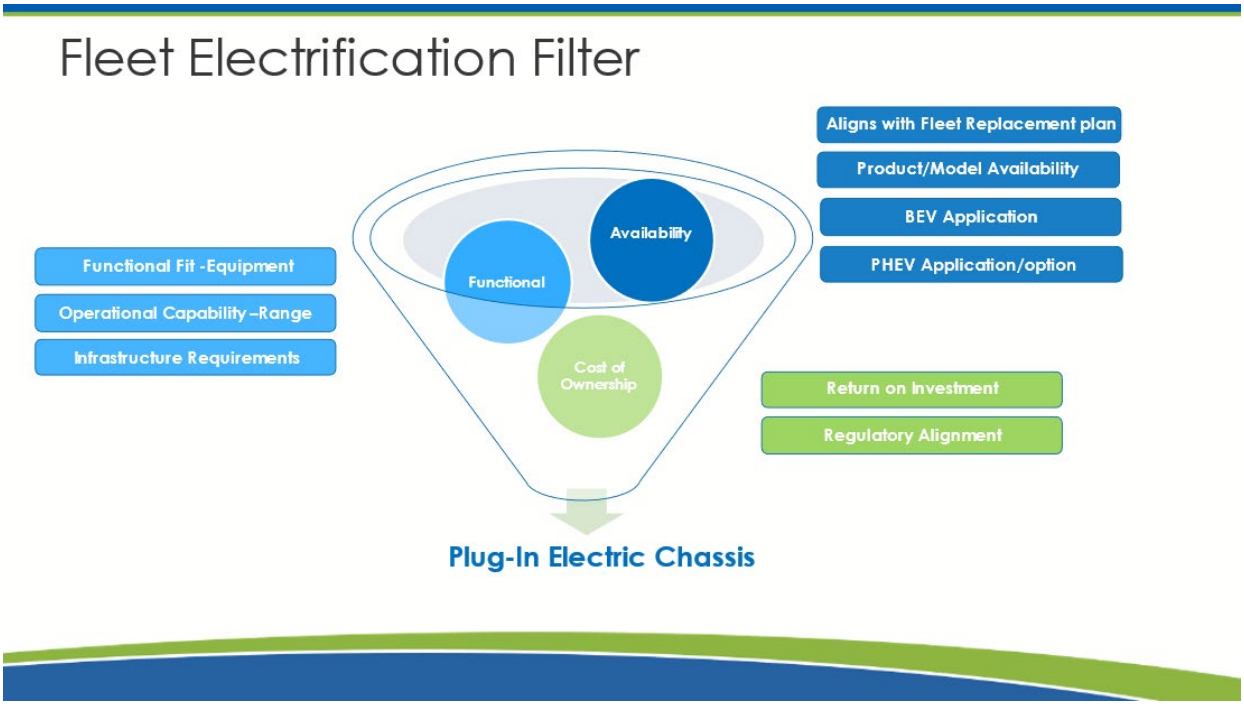
Assessment of Fleet Electrification Viability

Consumers Energy Fleet Purchase Plan Vehicle Electrification

Purpose and Methodology

The purpose of this analysis is to:

> "Provide an assessment of the viability of using electric vehicles for all already scheduled light-duty vehicle replacements between now and 2030."



This following paper discusses the technical and operational viability of replacing Internal Combustion Engine powertrains ("ICE") fleet vehicles with a vehicle of similar function but with an electric vehicle ("EV") powertrain in the light duty class (class one and two). As requested, the units under consideration are all light duty units identified for replacement now through 2030. These units mostly include sedans, sport utility vehicles, and pick-up trucks that support various departments and operations. This assessment additionally includes a discussion regarding market availability of EVs for the purposes of fitness and functionality in the Company's fleet as this is critical to viability when comparing the needs of Company fleet support and the reality of what is available to replace an ICE unit with an EV without sacrificing fleet support.

The Company prefers to support Michigan-based auto manufacturers when considering replacing an ICE vehicle with an EV whenever possible. Even so, there are many EVs that are not built

with a commercial fleet/support design, and therefore are usually higher purchase costs associated with more luxury type appointments not suitable to support the work (leather seats, expensive alloy wheels and tires, etc.). The Company strives to acquire EVs that can support the work while limiting the appointments and features that can raise purchase prices or can present maintenance challenges in the future.

Rather than evaluating vehicles through theoretical EV benchmarks (range specs, OEM stated ranges, or best-case assumptions), this review prioritizes:

- Observed mileage patterns
- Tooling, payload, and upfit requirements
- Geographic and duty-cycle realities
- Market availability of fit-for-purpose EV replacements
- EV trials already conducted by the organization

Vehicles were assessed by category (sedans, SUVs, pick-ups, and vans), then cross-referenced with key considerations that would support replacement of an ICE unit with an EV unit. The Fleet Electrification Filter vehicle requirements (see below) outlines key defined attributes considered by fleet stakeholders. In short, electrification decisions must be made pragmatically, not ideologically.

Fleet Composition Overview

The units in the purchase plan are dominated by fleet pick-up trucks and vans, with a smaller number of sedans and SUVs.

Broadly, the light duty potential ICE to EV fleet breaks down into:

- Sedans
- Sport Utility Vehicles (SUV)
- Pick-up Trucks
- Vans (cargo)

The distribution of vehicle types is important to note because EVs capable of replacing current ICE units varies significantly by vehicle class and brand, and most of the electrification challenges that occurs is related to or tied directly to functionality (like work-truck upfit compatibility, loaded cargo van range etc.) not a fundamental resistance to electrification in principle. As the electrification filter illustrates, (see above), a key piece of fleet electrification consideration is how a potential EV replacement will fit to support the work required to serve customers, not just related to meeting drive range needs

Sedans: Highest Electrification Viability

Sedans represent the clearest and probably most viable electrification opportunity in the purchase plan. In many instances, sedans only require a few modifications such as safety lighting if needed and do not require carrying heavy equipment. The current drive patterns for many sedans support the replacement of the current ICE unit with an electric unit. However, it is still critical to confirm the needs of the groups utilizing these units to confirm a good fit.

Key Factors Supporting Sedan Electrification

1. **Predictable Duty Cycles**
   Sedan assignments appear to involve:
   - Regional travel
   - Service Center-to-site-service center driving
   - Limited payload, upfit requirements
2. **Adequate EV Market Coverage**
   The EV sedan and compact crossover market already supports:
   - 250+ miles of real-world range
   - All-weather operation
   - Minimal payload impact on range
3. **Low Operational Risk**
   Unlike field trucks, sedans:
   - Rarely have to tow any equipment, trailers etc.
   - Usually do not require rear trunk or bed space or upfitting.
   - Are less likely to be loaded with heavy equipment.

Electrification Viability: HIGH

Sedans could be prioritized for near-term electrification (first-wave conversions). The spreadsheet already reflects alignment within fleet planning assumptions, and no systemic barriers are identified.

SUVs: Mixed but Often Viable

SUVs in the purchase plan sit between sedans and pick-ups in terms of viability.

Supportive Indicators

In the instance of SUVs, the market could support the viability of EVs in this category as range capabilities improve with each model year. The EV replacements planned for vehicles in the SUV category could match well with currently offered units (Equinox EV for example). There are two use cases that may work well for EV replacement but have varying viability on the SUV category. For most passenger carrying SUVs, the viability of an electrified unit could work well. For SUVs units that have a more work truck role, electrification may be more challenging due to payload, field inspection, and forestry roles putting them in situations that require more frequent charging. For these particular units, fleet needs to work closely with the business's use case and determine what EVs (if any) work best.

Electrification Viability: MODERATE

SUV electrification is viable where SUVs are used more as passenger support vehicles. Where SUVs are acting as substitutes for pick-ups, electrification becomes less viable.

Pick-ups: Constraints that Limit EV Adoption

Pick-ups are the Company's largest vehicle category and the largest electrification challenge. The viability of an EV pick-up truck relies heavily on its intended use. Where pick-up trucks require the Company standard spec 8-foot bed for some pick-trucks, an EV pick-up truck may

not work well as most EV pick-up trucks are built with shorter beds. In some cases, the Company is targeting smaller pick-up trucks where there is no EV option currently available.

Core Barriers to Pick-Up Electrification

Bed Size & Payload

Many Company pick-up trucks operate in field roles that require longer bed configurations for specialized racks and/or toolboxes. Current EV pick-ups offer shorter bed lengths and can lose significant range carrying or pulling heavy loads. When considering an EV pick-up truck, it is important to note these limitations to avoid compromising operations.

Duty Cycle & Uptime Requirements

Pick-up truck deployment often requires long field days that involve longer distances between charging or public charging. Pick-up trucks are also critical for storm or other emergency response readiness and must be able to operate in freezing weather, where up to 30% of range reduction can occur.

EV range degradation under:

- Cold temperatures – EV range drops as ambient temperatures drop.
- Heavy payloads – Cargo van carry the weight of shelving, supply materials and tools that can significantly reduce range.
- Longer trips at highway speeds – Driving long distances at 70 MPH in any EV significantly reduce overall range, especially on colder days when cabin temperatures require heating.

Idle-heavy work cycles – Some units have limited dwell time that may require more time to fully charge EV battery.

Market Gaps

While vehicles like the Silverado EV (battery only EV that is capable of 490-mile range) and the planned RAM EREV (equipped with a range-extender EV capable of over 600-mile range) are available, they are still noted as potential future solutions. For the purposes of this assessment, these two vehicles represent some of the best potential solutions because of their work truck specifications.

Electrification Viability: LOW (for many pick-ups)

Except for a small subset of lighter-duty pick-ups, most pick-up roles in this fleet should not be electrified with current technology without compromising mission capability.

Range-Extender EVs: An Opportunity

The technology to extend the range and field capability of an electrified pick-up truck is planned for 2026 and 2027 model years from two Michigan manufacturers, offering an opportunity to replace a light duty ICE pick-up truck with a plug-in pick-up with longer range, and shorter refueling times. An EV range extender is an auxiliary power unit, in this and most cases a small internal combustion engine, to supplement the range provided by the plug-in battery. The Company is closely monitoring planned offerings in this category including the vehicles below.

- RAM 1500 REV due late 2026
- Ford Lighting EREV planned for 2027, (both with plug in battery and range extender powertrains).

Why This Matters

Range-extender EVs address one of the single biggest EV hurdles: refueling timing and cargo weight limitations. While the Company has not had the opportunity to test a range extender equipped pick-up truck, the Company already has vehicles with this design in its fleet. The Chevrolet Volt is designed to use a battery for full EV driving for approximately thirty-five miles but is built with a small engine that charges the battery to continue driving after the electric only range has been depleted. This keeps the EV on the road for a longer period, shortening the refueling time until the unit can plug back in for the duration needed to fully recharge the battery. Pick-up trucks equipped with range extender EV powertrains represent an opportunity for the Company to add EV vehicles that lower fuel consumption without compromising storm response or weight related range reductions. These pick-trucks also offer a measure of range certainty, and less range anxiety under load, that full battery electric trucks struggle to provide. For pick-up truck opportunities where the size of the pick-up bed can acceptably be less than eight (8) feet, the coming offerings of range extender work truck equipped EV trucks from Michigan based manufacturers represent a promising opportunity.

Limits Still Apply

Even with EREVs:

- Bed size constraints remain – these must be replaced on a case-by-case basis through discussions with specific groups on how they are using their pick-up truck beds for supplies, upfits etc.
- Cost premiums may be high.

Electrification Viability: CONDITIONAL

Range-extender EVs represent a second-wave opportunity, but not a universal solution. The range extender power train strategy will be new to the market and while it is expected to increase pick-up truck viability in the EV space, real world use will determine whether these units will truly deliver on ICE to EV return on investment expectations, and manufacturer commitment to this approach going forward.

Cargo Vans: Electrification Fit Challenge to Date

No category is more challenging to electrify at this time than cargo vans. Cargo vans present a unique problem in that they require an upfit (usually consisting of metal shelving or drawers etc.) that carry equipment, tools, and other materials required to complete the work needed by crews. These vans must carry weight that is significant and must be considered when selecting a suitable EV replacement that would not add refueling (charging) time or other constraints to completing the work required. The potential need for midday charging requirements depending on how long an EV is deployed is also a key consideration. There may be limited opportunities to charge at public DC Fast Chargers.

The Company already has EV cargo van experience in the current fleet in use and has been used for relatively short distances as the Company learns more about their capabilities before purchasing more units.

The Company also had the opportunity to test a high roof EV cargo van. During the tests, the Company found that even under the no load conditions range the vehicle's use was not promising considering how much weight the van would have to hold once it was upfitted and loaded with tools and equipment supplies. There was feedback in regard to whether the van set up potentially would not work well with expectations from the workforce using them.

Core Constraints

1. **Upfit Weight** - Cargo vans are heavily modified with:
    - Shelving
    - Cabinets
    - Equipment

2. **Cold-Weather Penalty** - Vans are more impacted by:
    - Heavy upfits for shelving, tools and equipment loads.
    - HVAC load – many vans are deployed on the gas side of the business requiring workforce support.
    - Idling for cabin, equipment support
    - Stop-and-go driving.

Electrification Viability: VERY LOW

Based on direct operational experience, electrifying the Company's cargo vans should be avoided until:

- Battery energy density significantly improves, or
- Hybrid / REEV vans become commercially viable.
- Faster public charging solutions are available.

Conclusion

Vehicles Suited for Near-Term Electrification

- Sedans

- Passenger SUVs
- Light-duty pick-ups with minimal bed and payload needs (limited cases)

Vehicles Not Suited for Electrification Today

- Service vans (heavier loads – upfits, tools, supplies)
- Heavy-use pick-ups.
- Unit requiring:
    - Long beds
    - Heavy upfits.
    - Emergency readiness.

Transitional Technologies to Watch

- Range-extender electric pick-ups.
- Plug-in Hybrid pick-up trucks.
- Plug-in hybrid vans (if commercially viable).

Final Assessment

The Company's method towards fleet electrification is a mature, evidence-based approach. The limiting factors are not resistance or inertia—they are grounded in key items to consider including range, payload, learnings from current EVs and market availability. A selective electrification strategy, focused on sedans, appropriate pick-up trucks, and SUVs, while protecting mission-critical work vehicles, is operationally necessary.

Based on the Company's experience with both plug-in and fully battery electric vehicles, as well as workforce adaptation to the integration of electrified vehicles into daily operations, two primary attributes have emerged as critical filters in the fleet electrification replacement decision process: functional suitability and operational capability, particularly regarding range requirements. The Company has taken the opportunity to inspect, or test drive several EV

vehicles from start-up manufacturers, as well as established Michigan based manufacturers. There have been a couple instances where the manufacturer of the EV that the Company test drove failed and is no longer in business. There are other instances where established manufacturers have pulled back their EV offerings in response to current electrification acceptance. While both were not a good fit from a function perspective, it should be noted that there are also some reservations as to whether some EV vehicles and manufacturers will still be viable in the future (one of the vehicles the Company test drove from a well-established Michigan based manufacturer is no longer being produced just two years later). In both cases, the Company has been conservative in its approach, favoring a more measured, tactical, and pragmatic method to replacing ICE units with EVs. This is because the margin for error can significantly affect the work. It would not be to the Company's advantage to purchase vehicles from manufacturers that are not viable for the duration of a purchased unit's lifespan. Therefore, while the Company is still pursuing viable fleet electrification where possible, it must proceed in a manner that is seamless in its approach to the work fleet must support.

Fleet order requirement:

"Include more details regarding existing vehicle usage by vehicle specification."

Fleet Standard 06:

Fleet Standard Use: The Consumers Energy Fleet Standard 06 is a 4-door sedan used for general personnel transportation. The Standard 06 may or may not be a company marked vehicle.

Company Use: Common

Fleet Standard 07:

Fleet Standard Use: The Consumers Energy Fleet Standard 07 is a 4-door compact SUV used for general personnel transportation. The Standard 07 may or may not be a company marked vehicle.

Company Use: Common

Fleet Standard 22:

Fleet Standard Use: The Consumers Energy Fleet Standard 22 is a company marked ½ ton pickup. This vehicle is for general use and personnel transportation.

Company Use: Common

Fleet Standard 23:

Fleet Standard Use: The vehicle is a one ton Cargo van intended to transport Service personnel who provide a multitude of service. The van carries a crew of one or two people and travels paved roads at highway speeds. In some situations, this vehicle is operated at night. In special applications the vehicle will tow.

Company Use: Common

Fleet Standard 24:

Fleet Standard Use: The Fleet Specification 24 Cathodic van is a ½ ton (120.6" wheelbase) cargo van. It will be used to transport tools and equipment utilized by our Cathodic Operations employees. This unit will be upfit with Sortimo storage products and shelving units.

Company Use: Common

Fleet Standard 25:

Fleet Standard Use: The vehicle is a half-ton all-wheel-drive 135" wheelbase cargo van intended to transport service personnel who provide a multitude of service. The van carries a crew of one or two people and travels paved roads at highway speeds. In some situations, this vehicle is operated at night.

Company Use: Common

Fleet Standard 26:

Fleet Standard Use: The fleet specification 26 is intended to transport Electric Substation personnel. The truck normally carries a crew of one or two people. The vehicle shall be expected to tow trailers not exceeding 7,000lb gross trailer weight and a maximum tongue weight of 1,000lb.

Company Use: Electric

Fleet Standard 27A:

Fleet Standard Use: The fleet specification 27 is intended to transport Gas T&S personnel for performing measurement regulation and pipeline storage work methods. The truck normally carries a crew of one or two people. In some situations, this vehicle is operated at night. The vehicle shall be expected to tow trailers not exceeding 7,000lb gross trailer weight and a maximum tongue weight of 1,000lb.

Company Use: Gas

Fleet Standard 27B:

Fleet Standard Use: The fleet specification 27B is intended to transport personnel and equipment to support the utility. The truck normally carries a crew of one or two people. In some situations, this vehicle is operated at night.

Company Use: Gas

Fleet Standard 28:

Fleet Standard Use: The Fleet Standard 28 is a ¾ ton 2wd or 4wd drive pickup that may have various uses. This vehicle configuration is spec'd for application in which it will be used.

Company Use: Common

Fleet Standard 36:

Fleet Standard Use: The fleet specification 36 is intended to transport electric meter personnel who set and remove electric meters. The truck normally carries a crew of one or two people. In some situations, this vehicle is operated at night.

Company Use: Electric

Fleet Standard 37:

Fleet Standard Use: This vehicle consists of a light-duty 84" CA gasoline dual rear wheel four-wheel drive extended cab chassis with 186" wheelbase. Installed on the cab chassis is a custom service body 94" wide and 133" long. The Fleet specification 37 gas construction service truck is intended to support gas construction personnel who maintain gas distribution and transmission pipeline. The truck normally carries a crew of one or two people and travels paved or gravel roads. In some situations, this vehicle is operated at night and off road. This vehicle shall be expected to tow trailers with a maximum gross weight of 14,000lb and have a maximum tongue weight of 2,800lb.

Company Use: Gas

Fleet Standard 39:

Fleet Standard Use: The vehicle is a high roof extended-length cargo van with a 148" WB. The Fleet Specification 39 Thumper van is used primarily for electric underground fault detection. This unit includes a van interior package and an arc reflection system.

Company Use: Common

Fleet Standard 41:

Fleet Standard Use: This vehicle consists of a light-duty 60" CA gasoline dual rear wheel four-wheel drive extended cab chassis. Installed on the cab chassis is a custom service body 94" wide and 118" long including a 16" tail shelf. The standard includes supplier provided welding equipment and deck mounted crane. The Fleet specification 41 light duty welding truck is intended to transport Gas Distribution and Gas T&S personnel who weld and maintain gas distribution and transmission pipelines. The truck normally carries a crew of one or two people and travels paved or gravel roads. In some situations, this vehicle is operated at night and off road. This vehicle shall be expected to tow trailers with a maximum gross weight of 14,000lb and have a maximum tongue weight of 2,800lb.

Company Use: Gas

Fleet Standard 42:

Fleet Standard Use: The fleet specification 42 is intended to transport personnel and materials to support the utility. It has an enclosed service body that allows for personnel to assemble materials in a controlled environment and then install them on the jobsite. The truck normally carries a crew of one or two people. In some situations, this vehicle is operated at night. The vehicle shall be expected to tow trailers not exceeding 14,000lb gross trailer weight and a maximum tongue weight of 1,400lb.

Company Use: Common

Fleet Standard 43:

Fleet Standard Use: This vehicle is a light-duty, 16,500 lb. GVWR regular cab, four-wheel drive, 60" CA, gasoline dual rear-wheel chassis up-fit with a Consumers Energy specification two-to-three-yard dump body and Consumers Energy Fleet accessories. Its intended use is to haul debris from excavation sites and transport gas construction personnel and materials. The truck may also pull a plastic reel trailer, small trencher, directional boring machine, flashing arrow board, or compressor. The expected towing capacity when the dump is empty is 14,000lb gross trailer weight and 2,800lb tongue weight.

Company Use: Common

Fleet Standard 44:

Fleet Standard Use: This Vehicle is used primarily for construction and maintenance of the Company's underground gas distribution systems. A crew of two is assigned to the truck. The truck is required to carry material cargo supplies and tools weighing approximately 7,000 pounds for installation of gas distribution facilities. The truck normally pulls a trailer loaded with trenching equipment with a combined weight of 30,000 lbs. The truck is expected to travel at highway speeds and be capable of off-road travel as well. The truck will be equipped with lighting for nighttime site work and enhanced lighting for roadway safety. The truck will be designed and built with ergonomic features focused on safe operations for the crew.

Company Use: Gas

Fleet Standard 45:

Fleet Standard Use: The fleet specification 45 is intended to support garage service repair calls. The truck normally carries a crew of one or two people. In some situations, this vehicle is operated at night. The vehicle shall be expected to tow trailers not exceeding 7,000lb gross trailer weight and a maximum tongue weight of 1,000lb.

Company Use: Common

Fleet Standard 54:

Fleet Standard Use: This specification is for a 4x2 regular cab chassis with dual rear wheels. The chassis has a GVWR of 33,000 lbs. and a GCWR of 80,000 lbs. The cab to axle is 84", wheelbase 150", and axle to frame of 63". The truck will be used primarily for transporting materials in its 5-yard struck hydraulic dump body. The vehicle shall be capable of towing equipment trailers weighing up to 30,000 lbs. provided are street side and curbside under body toolboxes. An electric tarping system with a tarp tensioner is provided. Also provided are Oak side boards. The truck normally carries a crew of one to two people and travels on paved or gravel highways.

Company Use: Common

Fleet Standard 55:

Fleet Standard Use: This specification is for a 6x4 regular cab chassis with tandem dual rear wheels. The chassis has a GVWR of 54,000 lbs. and a GCWR of 80,000 lbs. The cab to axle is 123", wheelbase 189", and axle to frame of 75". The truck will be used primarily for transporting materials in its 10-yard struck hydraulic dump body. The vehicle shall be capable of towing equipment trailers weighing up to 30,000 lbs. provided are street side and curbside under body toolboxes. An electric tarping system with a tarp tensioner is provided. Also provided are Oak side boards. The truck normally carries a crew of one to two people and travels on paved or gravel highways.

Company Use: Common

Fleet Standard 57:

Fleet Standard Use: This vehicle is utilized as an Electric and Gas Operations derrick crane truck. The derrick chassis has either a 6x4 or 6x6 chassis. The truck is utilized for construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off-road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.

Company Use: Common

Fleet Standard 59:

Fleet Standard Use: The Fleet Standard 59 is a miscellaneous specification for unique vehicles needed to conduct Gas Operations.

Company Use: Gas

Fleet Standard 60:

Fleet Standard Use: The fleet specification 60 is intended to transport electric substation personnel for performing substation maintenance work methods to support the utility. The truck normally carries a crew of one or two people. In some situations, this vehicle is operated at night. The vehicle shall be expected to tow trailers not exceeding 14,000lb gross trailer weight and a maximum tongue weight of 1,400lb.

Company Use: Electric

Fleet Standard 64:

Fleet Standard Use: This vehicle is an Electric Operations 41-foot aerial beam truck, dual rear wheel with a 120-inch-long steel service body. The truck will have a 3,000-pound payload capacity. This is utilized with one operator performing service and troubleshooting activities on the electric service infrastructure. The unit is utilized on and off paved roads in addition to off road conditions to access the electric infrastructure. This vehicle is designed to provide versatile platforms and used during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 65:

Fleet Standard Use: This vehicle is an Electric Operations 38-foot aerial beam truck, dual rear wheel with a 120-inch-long steel service body. The unit is utilized with one operator performing service and troubleshooting maintenance and repair of streetlights on the electric service infrastructure. The unit is utilized on and off paved roads, to access the electric infrastructure. The vehicle is designed to provide a versatile safe platform and used during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 66:

Fleet Standard Use: This specification is intended to be used primarily for maintenance of the underground electric utility system infrastructure. The step van primarily travels paved roads and supports a crew of two people. A maximum payload of 10,000lbs (tools, materials, accessories, fuel, trailer, and occupants) is expected to be transported by the vehicle. In some situations, this vehicle is operated at night. The step van is equipped with many accessories that support the utility's work methods. The step van shall be expected to tow trailers not exceeding 7,000lb gross trailer weight and a maximum tongue weight of 1,000lb.

Company Use: Electric

Fleet Standard 67:

Fleet Standard Use: The Electric Substations Truck is 25,500 lb. GVWR, diesel powered, dual rear wheel cab-chassis outfitted with a 111" long service body. The unit has a minimum payload capacity of 5,000 lbs. and towing capacity of not more than 15,000 lbs. The owner supplied chassis has a 64.45 cab to axle dimension, vertical exhaust, air brakes and 245/70R19.5 tires. The truck normally carries a crew of one to three people and travels on paved or gravel highways and snow-covered substation driveways. This vehicle is designed to provide a versatile platform for installing and maintaining electric substations.

Company Use: Electric

Fleet Standard 68:

Fleet Standard Use: The chassis is a 158" wheelbase, 14,500 GVWR, and a V-10 gasoline engine. Stripped chassis specifications are stated in section 4.0 specifications chassis. The body is a 14-foot cargo length walk-in van up fit and commissioned to Consumers Energy specifications. The Fleet Standard 68 14-foot GAS Service walk-in vans are intended to transport personnel and materials and provide an enclosed work environment. This vehicle is required to tow up to a 7,000-pound GVWR trailer with electric brakes. The vehicle will travel 10,000 to 15,000 miles per year and has a life expectancy of 20 years. The Fleet Standard 68 14-foot GAS Service walk-in van carries a crew of one or two people and travels on paved roads. In some situations, this vehicle is operated at night.

Company Use: Gas

Fleet Standard 75:

Fleet Standard Use: This vehicle is an Electric Operations Digger Derrick truck with single rear wheel four when drive chassis. The truck is utilized for electric overhead construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing purposes of various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 77:

Fleet Standard Use: This vehicle is an Electric Operations Digger Derrick truck. The digger derrick chassis is either a 6x4 or 6x6 chassis. The truck is utilized for electric overhead construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 82:

Fleet Standard Use: This vehicle is an Electric Operations Aerial Device truck with single rear axle four-wheel drive chassis. The truck is utilized for electric overhead construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing purposes of various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.
Company Use: Electric

Fleet Standard 83:

Fleet Standard Use: This specification is a single axle dual rear wheel 4x2 cab-chassis with a minimum GVWR of 33,000 lbs. and a minimum GCWR of 60,000 lbs. and a CA of 120". The cab chassis is up fitted with a 16’ flatbed body with stake racks and lift gate. The truck is a specialized piece of equipment used to transport and deliver materials. The truck normally carries a crew of one or two people. In some situations, this vehicle is operated at night.

Company Use: Common

Fleet Standard 85:

Fleet Standard Use: The chassis is a tandem axle general freight regional haul 6X4 day cab tractor with fifth wheel hitch.

Company Use: Common

Fleet Standard 86:

Fleet Standard Use: This chassis is designed to have various platform bodies 16, 20, and 24 feet long.

Company Use: Common

Fleet Standard 89SM:

Fleet Standard Use: This vehicle is an Electric Operations Aerial Device truck with either a 6x4 or a 6x6 chassis. The truck is utilized for electric overhead construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing purposes of various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 89TM:

Fleet Standard Use: This vehicle is an Electric Operations Aerial Device truck that has either a 6x4 or a 6X6 chassis. The truck is utilized for electric overhead construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing purposes of various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 90A:

Fleet Standard Use: This specification is for a 4x2 dual rear wheel flat-bed chassis. The chassis has a GVWR of 33,000 lbs. and a GCWR of 80,000 lbs. The cab to axle is approximately 120”, wheelbase 187”, and axle to frame of 75”. The flatbed body has incorporated into its storage bin packs both street side and curbside and a deck mounted storage box. Provisions are provided to carry either three or four reels of wire that would pay out either over both sides of the trucks or out the rear. The truck is expected to carry up to 12,000lb of payload and capable of towing a tag trailer up to 30,000lb GVWR.

Company Use: Electric

Fleet Standard 90B:

Fleet Standard Use: The chassis has a GVWR of 33,000lbs. The GCWR is 80,000lbs. The cab to axle is 120” with the wheelbase approximately 187”. The AF is 75”. The chassis will have a flatbed body with behind the cab bin packs installed by an up-fitter. Also installed by an up-fitter is a PTO driven under deck air compressor. The truck is expected to tow up to a 30,000lb GVWR tag equipment trailer.

Company Use: Gas

Fleet Standard 94SM:

Fleet Standard Use: This vehicle is an Electric Operations Aerial Device truck that has either a 6x4 or a 6x6 chassis. The truck is utilized for electric overhead construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing purposes of various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 94TM:

Fleet Standard Use: This vehicle is an Electric Operations Aerial Device truck that has either a 6x4 or a 6X6 chassis. The truck is utilized for electric overhead construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing purposes of various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 96S:

Fleet Standard Use: This vehicle is an Electric Operations Aerial Device truck with either a 6x4 or a 6x6 chassis. The truck is utilized for electric overhead construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing purposes of various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 96T:

Fleet Standard Use: This vehicle is an Electric Operations Aerial Device truck with dual rear wheel has either a 6x4 or a 6X6 chassis. The truck is utilized for electric overhead construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing purposes of various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 97T:

Fleet Standard Use: This vehicle is an Electric Operations Aerial Device truck that has either a 6x4 or a 6X6 chassis. The truck is utilized for electric overhead construction and maintenance of the Consumers Energy infrastructure. The unit is operated with a crew at a work site. The vehicle is utilized on and off paved roads, in addition to off road conditions necessary to access the electric infrastructure. The vehicle is utilized for towing purposes of various utility application trailers including construction equipment and pole trailers. The vehicle is utilized during daytime and nighttime operations.

Company Use: Electric

Fleet Standard 98:

Fleet Standard Use: This specification consists of a chassis that will support a behind the cab mounted 23 ton rated 100-foot crane with a three to four section boom. Provided is a 21-foot-long steel flatbed behind the crane. Cargo caring capacity on the flat bed shall be rated for up to 12,000 pounds while the spec 98 is towing up to a 30,000-pound GVWR trailer. The chassis shall be capable of supporting the crane, flatbed body, up to 12,000 pounds of cargo on its flatbed, and tow a 30,000-pound GVWR trailer with an estimated 6,000-pound tongue weight and not exceed the state of Michigan maximum weight and axle load limits not using the bridge formula. Weights shall also not exceed tire manufacturer maximum loading each.

Company Use: Common

Fleet Standard 99:

Fleet Standard Use: The Fleet Standard 99 is a miscellaneous specification for unique equipment needed to conduct Electric Operations.

Company Use: Electric

Fleet Standard E10:

Fleet Standard Use: The Consumers Energy specification E10 is used primarily for utility construction throughout the state. This unit will be operated in diverse types of soil and conditions by our electric and gas crews. It will be utilized for the burial of service cable and gas line.

Company Use: Common

Fleet Standard E11:

Fleet Standard Use: The Consumers Energy Specification E11 - Medium Duty Trencher is used primarily for the installation of underground electric and gas infrastructure in diverse types of soil and conditions throughout the state. Standard Equipment consists of a backhoe, and a 48-inch trenching boom. Options would include a combination vibratory plow/trencher as well as rubber tracks.

Company Use: Common

Fleet Standard E12:

Fleet Standard Use: The use for this unit will be specified at the point of requirement.

Company Use: Common

Fleet Standard E20:

Fleet Standard Use: The Consumers Energy Fleet specification E20 is primarily used as a multi-purpose utility machine. Its many functions may include truck loading and trenching. The fleet specification E20 can also be used as a tool carrier. Front or rear couplers may be requested. Attachments such as front forks, rear hoe-packs and hammers may be utilized. The Fleet specification E20 will be operated on and off pavement and at times encounter soft underfoot soil conditions.

Company Use: Common

Fleet Standard E22:

Fleet Standard Use: The use for this unit will be specified at the point of requirement.

Company Use: Common

Fleet Standard E25:

Fleet Standard Use: This specification is a compact mini track loader with select attachments, securement devises, and transport trailer. The Consumers Energy Fleet specification E25 is primarily used as a multi-purpose compact rubber track loader with the abilities to operate many hydraulic work tools that support the utility.

Company Use: Common

Fleet Standard E26:

Fleet Standard Use: This specification is a skid steer loader provided with select attachments. The E26 is primarily used as a multi-purpose skid steer loader with pneumatic rubber tires or rubber tracks that will operate an assortment of standard flow hydraulic and non-hydraulic work tools that support the utility. This specification includes a transport trailer with machine securement included.

Company Use: Common

Fleet Standard E30:

Fleet Standard Use: This specification is a track dozer provided with select options. The E30 is primarily used as a multi-purpose small track type dozer for light stripping, grading, and cleanup utility work in soft underfoot conditions.

Company Use: Common

Fleet Standard E36:

Fleet Standard Use: This specification is a compact excavator provided with select attachments and transport trailer. The E36 is primarily used as a multi-purpose compact digging and trenching utility machine. Exact size is determined at point of order.

Company Use: Common

Fleet Standard E53:

Fleet Standard Use: This specification is for a standalone welder / generator. The use for this unit will be specified at the point of requirement.

Company Use: Gas

Fleet Standard E60:

Fleet Standard Use: The Consumers Energy specification E60 is used for material handling and field operations. This specification is a Forklift with selectable capacity and lift heights depending on business needs.

Company Use: Common

Fleet Standard E67:

Fleet Standard Use: The use of this Mobile Crane will be specified at the point of requirement.

Company Use: Gas

Fleet Standard E72:

Fleet Standard Use: The use for this Switcher Locomotive will be specified at the point of requirement.

Company Use: Generation

Fleet Standard E73:

Fleet Standard Use: This specification is a hydraulic excavator with a minimum operating weight of 47,000 lbs. and 153 horsepower. The maximum width over the track shoes shall be 10' 6". This machine has steel, 800mm triple grouser track shoes; an auxiliary hydraulic circuit with hydraulic lines ran to the end of the stick to operate optional hydraulic hammers, compactors, or hydraulic thumb. The machine is equipped with the manufacture's long undercarriage, standard boom length, and an approximate stick length of 9' 6".

Company Use: Gas

Fleet Standard E74:

Fleet Standard Use: The use for this Wheel Dozer will be specified at the point of requirement.

Company Use: Generation

Fleet Standard E75:

Fleet Standard Use: The use for this Tracked Dozer will be specified at the point of requirement.

Company Use: Generation

Fleet Standard E76:

Fleet Standard Use: The use for this Articulated Haul Truck will be specified at the point of requirement.

Company Use: Generation

Fleet Standard E78:

Fleet Standard Use: The use for this Off-Road Water Truck will be specified at the point of requirement.

Company Use: Generation

Fleet Standard E79:

Fleet Standard Use: The Consumers Energy specification E79 directional boring machine is used primarily for the installation of underground infrastructure for Consumers Energy. Manufacture standard features on the drill will be utilized. This Directional Drill and trailer combination is available in 3 different sizes, to be determined at point of order.

Company Use: Common

Fleet Standard E80:

Fleet Standard Use: This standard provides the specifications for a track carrier to mount a digger derrick pin on a bucket to be used in adverse weather or adverse ground conditions. This unit shall comply with all ANSI and federal regulations that apply to this vehicle.

Company Use: Electric

Fleet Standard E81:

Fleet Standard Use: The Consumers Energy specification E81 backyard pole setter and transport trailer is used primarily for construction and maintenance of the electric overhead utility infrastructure. The principle operating environments this unit are confined, restrictive, and limited accessible areas that require the equipment as specified within this scope.

Company Use: Electric

Fleet Standard E90:

Fleet Standard Use: The Consumers Energy specification E90 Diesel All Terrain Utility Vehicle is used primarily for supporting the utility by transporting people, material, and supplies.

Company Use: Common

Fleet Standard E95:

Fleet Standard Use: This Aerial Platform Lift equipment is used primarily for maintenance, repairs, and service in and around our electric substations.

Company Use: Common

Fleet Standard E99:

Fleet Standard Use: The Fleet Standard E99 is an equipment standard for miscellaneous equipment used.

Company Use: Common

Glossary

Fleet Standard: the specific configuration of a unit to meet the needs of its original intended purpose.

Fleet Standard Use: a description and usage of a vehicle to help determine the best fit in the workforce.

Company Use: the principal business function of the company the vehicle is utilized. (Gas, Electric, Generation, and Common)

Gas: vehicles used only for the gas business functions.

Electric: vehicles used only for the electric business functions.

Generation: vehicles used only for the generation business functions.

Common: vehicles that may be used for all business functions such as gas, electric, and generation.

STATE OF MICHIGAN

BEFORE THE MICHIGAN PUBLIC SERVICE COMMISSION

In the matter of the application of **CONSUMERS ENERGY COMPANY** for authority to increase its rates for the generation and distribution of electricity and for other relief.	))))))	Case No. U-22070

EXHIBITS

OF

KURT K. LAFRANCE

ON BEHALF OF

CONSUMERS ENERGY COMPANY

June 2026

CONSUMERS ENERGY
ELECTRIC ASSET MANAGEMENT

High Voltage Distribution(HVD) Pole Inspection Specifications

1. GENERAL SPECIFICATIONS

1.1. Consumers Energy shall provide all maps necessary for the wood pole inspection work to be performed.

1.2. The Contractor shall furnish all tools, equipment, inspection tags, bore tags, red tags and labor as required for the completion of wood pole inspection as prescribed in these specifications.

1.2.1. Each foreman employed by the Contractor working for Consumers Energy shall be a permanent, full-time employee of the Contractor. Each foreman shall have adequate training and not less than eight weeks experience as a Pole Inspection Foreman.

1.2.2. Each supervisor employed by the Contractor working for Consumers Energy shall be a permanent, full-time employee of the Contractor having not less than two years experience in supervising pole inspection crews.

1.2.3. The Contractor shall supply to a Consumers Energy representative written verification of the training and experience of each foreman and supervisor working for Consumers Energy before such work begins.

1.3. The Contractor shall inspect all poles with Consumers Energy facilities on them, which are connected electrically to the circuit or line section specified. All stub poles that are used for guying purposes should also be inspected. Poles within the protective fence of an electric substation shall also be inspected. Vacated or cut-off poles that had/have 3rd party attachments located adjacent to a Consumers Energy pole shall not be inspected, but the adjacent pole inspection record shall include yes or vacant value in the *PULL POLE* field.

1.3.1. For safety purposes, at least one individual per pole inspection team must attend substation entry training provided by Consumers Energy prior to entering a substation peremeter fence.

1.4. A representative of the Contractor shall be involved in a periodic conference call/meeting with Consumers Energy representatives to discuss inspection status and issues that may arise.

1.5. The Contractor shall electronically report the following information to Consumers Energy's representative each Monday by 12:00 noon (the format will be agreed upon with the Consumers Energy representative in advance):

1.5.1 Number of people who worked the previous week.

1.5.2 Specific days of week that each person worked during the previous week.

1.5.3 Specific circuit or line section that each crew worked during the previous week.

1.5.4 Planned circuit or line section of each crew for the current week.

1.6. The Contractor shall obtain, at their expense, all necessary permits required to complete the work prior to beginning the work requiring such permits.

1.7. Monthly the Contractor shall submit electronically via E-mail to a designated Consumers Energy's representative an invoice for the entire circuits or line sections that were completed. The Contractor shall include with each invoice a statement summarizing all work performed in each category of billing units.

1.8. The Contractor shall submit pole inspection data per individual circuit or line section, with the following conditions:

1.8.1. The data will be in Microsoft excel and either Microsoft Access format (MDB file) or ESRI Shapefile format.

1.8.2. CE Attachment B – Data Format lists the required data to capture for each pole inspection with a specific schema for Microsoft excel and either Microsoft Access format or ESRI Shapefile format.

1.8.3. A template for Microsoft excel and either Microsoft Access MDB file or ESRI Shapefile format with the required specific schema will be provided.

1.8.4. Transfer of circuit or line section data, including photos, Microsoft excel file and Microsoft Access database file or ESRI Shapefile will be packaged as one zip file named with the name and number of the Line Section or Feeder ID. The zip file will be transferred using FTP (File Transfer Protocol).

1.8.5. A sample set of twenty-five (25) pole data records fulfilling all data requirements specified in CE Attachment B – Data Format are to be submitted two weeks before start of pole inspections for testing and validation purposes.

1.9. The Contractor will specify and follow their quality assurance and audit process. The Contractor will work with Consumers Energy on an agreed upon acceptance process to ensure inspection and data quality requirements are achieved.

1.10. All work, including obtaining, recording, and reporting of the inspection data shall be entirely satisfactory to Consumers Energy and shall be subject to inspection by and approval of Consumers Energy. Any work submitted needing correction may be rejected and/or may delay payment. Common data errors need to be identified and corrected before data is submitted.

1.11. Consumers Energy may request a sample data set of an incomplete inspected circuit or line section for auditing purposes.

1.12. Contractor shall return any items/materials received from Consumers Energy and not used for inspection purposes.

2. VISUAL INSPECTION & GPS LOCATION SPECIFICATIONS

2.1. The Contractor will perform a visual pole inspection of the applicable poles on each circuit or line section assigned and record data per 1.8 above.

2.2. The Contractor shall report any system threatening or safety concerns promptly to the designated Consumers Energy representative(s). This includes but is not limited to:

1) A pole that the contractor determines to be an immediate replacement.
2) Any hazard that the contractor determines is a threat to public safety.
3) A floating phase or neutral wire.
4) A broken or severely cracked crossarm.

2.2.1 The Contractor could be requested by a Consumers Energy representative to stay on site until relieved by Consumers Energy representative. Consumers Energy will reimburse Contractor for time spent on site at agreed upon time and material rate.

2.2.2 A follow up E-mail shall be sent to a designated Consumers Energy representative for said pole or hazard within 3 days of call-in. A report template will be provided.

2.3. The Contractor will install a Consumers Energy pole number tag placed immediately above the inspection tag (if present), if a legible existing Consumers Energy pole number tag is not already present.

2.3.1. The Consumers Energy pole number tag is a numbered circular metal tag that will be provided by Consumers Energy.

2.3.2. The existing or new pole tag number will be recorded at each pole location.

2.4. The Contractor will obtain GPS location data accurate to 2-5 meters or better for each inspected pole. GPS location data will be recorded using the WGS84 (UTM) Coordinate System as a standard. See CE Attachment B – Data Format for electronic data reporting format.

2.5. The Contractor will take one in focus picture of the inspected pole. Picture should contain in its frame all the attachments on that pole.

2.5.1. Photos shall be captured with a device capable of 5.0 megapixels or greater.

2.5.2. The image file name will contain the tag number of the pole, followed by the compass heading of the direction the camera was facing when the photo was taken. The compass heading should be specified as the four cardinal directions and the four ordinal directions (N,NE,E,SE,S,SW,W,NW)

2.5.3. Image file must be in JPEG (.jpg) format.

2.5.4. For poles that are part of a muti-pole structure, photo shall include all poles of that structure.

3. POLE TEST INSPECTION SPECIFICATIONS

3.1. Consumer Energy’s prefered pole test inspection method is a device assisted test that helps identify poor pole conditions and voids.

3.2. The Contractor shall conduct a pole test inspection of all poles eleven (11) years old or older and which have not been inspected within the last five (5) years.

3.3. Designated poles shall be tested from ground line to 6 feet above ground line.

3.4. The Contractor shall install an agreed upon inspection tag at chest height on the road side of all tested poles.

3.5. The inspection tag shall have the name of the Contractor and the year of inspection stamped into the tag.

4. BORE TEST INSPECTION SPECIFICATIONS

4.1. The Contractor will perform a bore test on poles for the following reasons:

4.1.1. The pole test indicates the pole is decaying.

4.1.2. Visual decay is present.

4.1.3. Insects appear to be in the pole.

4.1.4. The pole has been backfilled or is discolored.

4.1.5. To satisfy a doubt about a pole's condition.

4.1.6. To determine the condition of a pole which was previously reinforced.

4.2. The Contractor shall only probe the pole surface if the pole has indication of defects from the visual or pole test inspections.

4.3. The Contractor shall follow the following bore test procedure:

4.3.1. Bore where either the pole test or visual inspection indicates the weakest point. Where two points are equally weak at the same level, bore the side of the pole perpendicular to the direction of the line.

4.3.2. If the pole test indicates decay or voids near ground, excavate to a depth of 6 to 8 inches and bore downward at a 45 degree angle. For poles installed in concrete or black top, bore downward at grade level at a 45 degree angle. (Read shell thickness on the 45 degree scale.) Poles with 1" shell thickness or less shall be indicated for replacement (Section 5.3).

4.3.3. For externally damaged sections, bore both the damaged side and 180 degrees from the damaged side.

4.3.4. For insect colonies, bore weakest point found during pole test.

4.3.5. Probe bored holes with depth gauge and record shell thickness. On all poles that are bored a shell thickness recorded in the appropriate data field is required. For poles where no void is found record a NV (No Void) in the *Bore* field. Record approximent height from ground line of minimum shell thickness in *Minimum Shell Thickness Height Field*.

4.3.6. Bore HVD candidate poles at 15" and 54" above the groundline to determine if it can be reinforced. (**Note**: "Candidate" poles are poles that qualify as replacement candidates per Section 5.1.2 Report the minimum shell thickness at 15" and 54" above the groundline. Report the pole as reinforceable if there is an average 2" of shell or greater at 15" above the groundline and an average 4" shell or greater at 54" above the groundline.

4.3.7. Plug all holes with 3" treated wood plugs.

4.3.8. Bore previously reinforced poles at the top of the steel truss. Identify previously reinforced pole as a replacement candidate if less than average 4" shell.

4.3.9. When inspection is complete replace any excavated soil, tamping it firmly around the pole butt. Make a small mound of soil to compensate for settling.

4.4. Inspect the pole for surface decay.

4.5. The Contractor will install an acceptable bore tag at chest height on the road side of all poles bore tested.

5. EVALUATION CRITERIA

5.1. The Contractor shall use the following bore test criteria to identify wood pole replacement candidates:

5.1.1 HVD Line Section Criteria

Original Circumference Just Above Groundline	Reduction of Circumference At or Below Groundline (Decayed Area)	Hollow Heart Minimum Allowable Thickness of Shell At Outer Decay Location	Pole Is A Replacement Candidate If Shell Thickness Is Less Than
35"	0"	2.0"	2.0"
	2"	2.0"	2.0"
	4.4"	Solid	Solid
	Greater than 4.4"	Candidate	-
40"	0"	2.0"	2.0"
	2"	2.0"	2.0"
	4"	2.6"	2.6"
	5.1"	Solid	Solid
	Greater than 5.1"	Candidate	-
50"	0"	2.0"	2.0"
	2"	2.2"	2.2"
	4"	2.8"	2.8"
	6.3"	Solid	Solid
	Greater than 6.3"	Candidate	-
60"	0"	2.3"	2.3"
	2"	2.6"	2.6"
	4"	3.1"	3.1"
	7.6"	Solid	Solid
	Greater than 7.6"	Candidate	-
70"	0"	2.7"	2.7"
	2"	3.0"	3.0"
	4"	3.4"	3.4"
	6"	4.0"	4.0"
	8"	5.4"	5.4"
	8.9"	Solid	Solid
	Greater than 8.9"	Candidate	-
80"	0"	3.0"	3.0"
	2"	3.4"	3.4"
	4"	3.8"	3.8"
	6"	4.3"	4.3"
	8"	5.2"	5.2"
	10.1"	Solid	Solid
	Greater than 10.1"	Candidate	-

5.2. Visual inspection can be used to identify rejected poles where there is severe decay at the top of the pole or where the pole is split or has large voids above chest height or other similar conditions. On all poles rejected due to visual inspection record reason in *Comments* field.

5.3. The Contractor shall install a red tag (white arrow) on all rejected poles at chest height on the road side of the pole, and indicate proper replacement value in the *ActionRequired* field.

5.3.1. Place the red tag "arrow up" if the pole was rejected from the visual inspection.

5.3.2. Place the red tag "arrow down" if the pole was rejected from the bore test inspection.

5.4. Replacement HVD candidate poles shall not be treated with wood preserving products unless the pole is reinforceable according to the criteria in 4.3.6.

6.0 Record Keeping

6.1 If the brand date is unreadable, estimate the manufactured year, height, and class of the pole and record as such.

6.2 Any poles that were unable to be inspected shall be recorded as follows:

- No in the *Accessible* field.
- Nearby GPS coordinate in GPS coordinate field.
- Additional location information in the *LocationDescription* field (ex. 200’ N of Pole# 1234567).
- A valid reason of why the pole is inaccessible in the *Comments* field (ex. Surrounded by water).

6.3 When testing multiple pole HVD structures, indicate which pole is being tested in the *HVD Structure Number* field. Example: #556N, #556S, #556W or #556E.

6.4 If the existing HVD pole is stubbed, indicate which pole is being tested in the HVD Structure Number field. Example: #556, #556stub.

6.5 If there is a guy pole attached to a HVD pole, indicate which pole is being tested in the HVD Structure Number field. Example: #556 (T pole), #556guy.

6.6 If there is a swamp fixture attached to the pole, indicate “swamp fixture” in the foundation type field.

6.7 A HVD pole with an air-break switch in single circuit lines may not have pole numbers on them; in such cases, use the switch number on the switch handle. Switches in double circuit lines should have pole numbers on them. Indicate the air-break switch number followed by “ABS” in the HVD Structure Number field. (ex. 177ABS)

6.8 For poles in substations, record “sub” in *HVD Structure Number* field for un-numbered substation poles.

7. HVD WOOD PRESERVATIVE TREATMENT SPECIFICATIONS

7.1. The Contractor will use only those wood preservative products listed on Attachment C for treating HVD wood poles.

7.2. The Contractor shall treat all HVD poles with groundline surface decay that reduces the original circumference of the pole by 2" or more.

7.3. The following method will be used to treat HVD poles with surface decay.

7.3.1. Excavate to a depth of 18".

7.3.2. Remove all external decay by chipping and wire brushing (avoid removing any good wood).

7.3.3. Remove all shavings and decayed material from the hole and surrounding area.

7.3.4. When possible, remove all attachments and replace when bandaging or preservative application is complete (never bandage over wire molding).

7.3.5. Apply bandage or preservative application so that it extends 3" above groundline. Cover the bandage or preservative with an approved moisture carrier.

7.3.6. Replace excavated soil and tamp. Do not place solid objects such as large rocks against the pole. Backfills shall be mounded around the pole to allow for settling.

7.3.7. No debris, loose soil, etc, is to be left in the pole area and shall be properly disposed of. Replace turf removed from excavation with care in its original location.

7.4. The contractor will treat all HVD poles with internal decay except replacement candidates which are not reinforceable. The contractor will treat all HVD poles infested with termite or ant colonies that are not replacement candidates or are reinforceable candidates. The contractor will internally treat all previously reinforced HVD poles with an average 4" shell or greater at 54" above groundline. The contractor shall treat all internally decayed HVD poles with an approved preservative, and in addition, decay voids/pockets shall be treated with pentachlorophenol or liquid copper napthenate.

7.4.1. The Contractor will follow the manufacturer's labeled directions for internal treatment of wood poles.

7.4.2. All holes will be plugged with 3" treated wood plugs following internal treatment.

Line No.	(a) Sub-Program	(b) Project Description, Line, Substation, or Location	(c) Projected Period Spending (Test)	(d) Units	(e) Unit Type	(f) Investment Category	Benefit Type	Benefit	Location
1	HVD Substation Reliability	WD0785 Delaney Reliability Improvement	851	1	Equipment	Circuit Breaker and Circuit Switcher Replacements	Customer*Minutes Avoided	2,674	Genesee
2		WD0951 Looking Glass Replace 4 Breakers	1930	4	Equipment	Circuit Breaker and Circuit Switcher Replacements	Customer*Minutes Avoided	10,697	Ingham
3		WD1108 Williams - Repl 156 Varmaster VSW	463	1	Equipment	Circuit Breaker and Circuit Switcher Replacements	Maintain System Voltage		Allegan
4		WD0064 Beecher Reliability Improvement	3516	6	Equipment	Circuit Breaker and Circuit Switcher Replacements	Customer*Minutes Avoided	16,046	Lenawee
5		WD1211 Bard Road Replace 156 Varmaster VSW	675	1	Equipment	Circuit Breaker and Circuit Switcher Replacements	Maintain System Voltage		Gladwin
6		WD0562 Engine Plant Replace 3 Gas Breakers	1256	3	Equipment	Circuit Breaker and Circuit Switcher Replacements	Customer*Minutes Avoided	8,023	Genesee
7		WD1169 Mecosta Repl 156 VSW	527	1	Equipment	Circuit Breaker and Circuit Switcher Replacements	Maintain System Voltage		Mecosta
8		WD0070 Water Street Replace 5 Breakers	2000	5	Equipment	Circuit Breaker and Circuit Switcher Replacements	Customer*Minutes Avoided	13,371	Bay
9		WD1085 Amber Replace 7 Breakers	2100	7	Equipment	Circuit Breaker and Circuit Switcher Replacements	Customer*Minutes Avoided	18,720	Mason
10		WD1160 Vevay Replace 156 Varmaster VSW	675	1	Equipment	Circuit Breaker and Circuit Switcher Replacements	Maintain System Voltage		Ingham
11		WD0235 Beals Rd Replace 600 Gas Breaker	500	1	Equipment	Circuit Breaker and Circuit Switcher Replacements	Customer*Minutes Avoided	2,674	Kent
12		WD0152 Cement City Repl 156 VSW	584	1	Equipment	Circuit Breaker and Circuit Switcher Replacements	Maintain System Voltage		Jackson
13		WD1108 Williams Replace 3 Breakers	1455	2	Equipment	Circuit Breaker and Circuit Switcher Replacements	Customer*Minutes Avoided	5,349	Allegan
14		WD1160 Vevay Replace 3 Breakers	1445	0	Equipment	Circuit Breaker and Circuit Switcher Replacements	Customer*Minutes Avoided	-	Ingham
15		WD0823 Diesel Tech Replace 199 (138kV)	500	1	Equipment	Circuit Breaker and Circuit Switcher Replacements	Customer*Minutes Avoided	2,674	Kent
16		WD1243 Amway Install Mobile Pad	100	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Kent
17		WD1448 Port Sheldon Yard/Drive Improvement	252	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Ottawa
18		WD0235 Beals Animal Mit, Security Improvement, Fence Replacements	991	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	Customer*Minutes Avoided	47,034	Kent
19		WD1117 Lawndale Install Drone	100	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Saginaw
20		WD1179 Skylark Install Drone	100	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Genesee
21		WD0085 Elm Street Install Drone	100	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Calhoun
22		WD1120 Hogsback Install Drone	100	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Ingham
23		WD0235 Beals Road Install Drone	100	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Kent
24		WD0738 Pipe Line Install Mobile Pad	100	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Bay
25		WD0967 Mcnally Install Mobile Pad	150	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Charlevoix
26		WD0021 Rogers Hydro, Security Improvement, Fence Replacement	168	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	Customer*Minutes Avoided	47,034	Mecosta
27		WD1167 West Shore Yard Improvements (Fence, Stone, Gate)	212	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	Customer*Minutes Avoided	47,034	Mason
28		WD0095 Croton, Security Improvement, Fence Replacement, Lighting	302	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	Customer*Minutes Avoided	47,034	Newaygo
29		WD0979 Halsey, Security Improvement, Fence Replacement	480	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	Customer*Minutes Avoided	47,034	Oakland
30		WD1220 Bass Creek, Security Improvement, Fence Replacement	512	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	Customer*Minutes Avoided	47,034	Ottawa
31		WD0730 Warren Replace Cap Fences	100	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Midland
32		WD0730 Warren Replace Perimeter Fence	578	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	Customer*Minutes Avoided	47,034	Midland
33		WD0837 Briggs & Straton Animal Mit, Security Improvement, Fence Replace	75	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	Customer*Minutes Avoided	47,034	Muskegon
34		WD0837 Briggs & Stratton Install Mobile Pad	100	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Muskegon
35		WD0046 Bullock Replace Cap Fence	80	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	System Operability		Midland
36		WD0046 Bullock Replace Perimeter Fence	589	1	Projects	HVD Subs Other Equipment and Animal Mitigation Projects	Customer*Minutes Avoided	47,034	Midland

PROJECT ASSUMPTIONS AND DETAILED CALCULATIONS

Assumptions

Reductions in Distribution (Labor & Material)

Savings due to a reduction in Routine Truck Rolls		
	$500	Routine Truck Rolls are saved because all Line Regulator Controls can be manipulated remotely in lieu of having to send personnel there to make voltage adjustments
System Population	1,889,301	
Average # of hours for Routine Work	1	
# of LVD Line Regulator Locations	1800	
Percentage of LVD Circuits that require adjustments to Line Voltage Regulators over the course of a Year	10%	It can be assumed that 10% of all Line Regulator Locations experience voltage adjustments over a 10 year period on average
# of LVD Line Regulator Locations Requiring Adjustments each Year	180	
Annual Average Savings due to Routine Truck Rolls	$90,000	
Reg Material & Labor Savings due to Life Extension for Regulator Tanks		
Average Regulator Tank Cost	$20,000	About 50 Reg Tank replacements take place on average in any given year across the LVD Fleet. Over a ten year period about 500 Regulator Tank replacements will be necessary to restore full functionality to LVD Line Regulator Locations. Regulator Tanks Useful life spans will be extended due to the preventaive maintenance tapping feature which has been turned on for all new replacement Regulator Controls. It is reasonable to assume that annual Regulator Tank Replacement will be reduced by at least 25% on an annual basis due to this preventative maintenance function over a ten year period.
Annual Reduction in # of Tank Replacements	12.5	
Storeroom Loadings Factor	2.3	
Average # of Regulator Tank Replacement per Year	50	
Average # of CE Crew Manhours for a Typical Tank Replacement	8	Includes Electric Field Lab Support functions including replacement of failed tanks at the specific location
CE Crew Hourly Rate (Loaded)	$440	
Average # of EFL Manhours for a Typical Tank Replacement	2.5	Includes Line Regulator Control Operation and Wiring Activities
EFL Hourly Rate (Loaded)	$110	
Total Average Annual Cost Labor Savings	$47,438	
Average Material Savings per Year due to Reg Tank Life Extension	$622,438	
Cellular Cost Savings due to Modem Configurations		
$7.00 per Month (250mb per month per device) based on Actual Data Usage from IT for a sample of Scada enabled Reg Devices	$7	
~900 Multiphase Pole Locations (3 phase)	900	
~340 Multiphase Pole Locations (2 phase)	340	
Annual Cellular Cost for a Single Phase Control 3 phase location	$226,800	
Annual Cellular Cost for a Single Phase Control 2 phase location	$57,120	
Annual Cellular Cost for a Multiiphase Control 3 phase location	$75,600	
Annual Cellular Cost for a Multiiphase Control 2 phase location	$28,560	
Annual Cellular Savings for a Multiphase Control 3 phase location	$151,200	
Annual Cellular Savings for a Multiphase Control 2 phase location	$28,560	
Full deployment starts in 2027 so full value of Cellular savings starts in the year 2027		
% Complete Deployment after 2024	75.33%	
% Complete Deployment after 2025	87.56%	
Total Annual Cellular Savings@100%	$179,760	
Reg Material Avoided Costs due to Replacement of Line Regulator Controls		Because Line Regulator Controls have been replaced across the fleet with all new Controls that have a 10 year Warranty at about 1800 locations across the fleet, a significant amount of costs to replace these controls has been avoided for the next ten years. Conservatively, we can assume that about 10% of these controls would have failed each year starting with the year 2027. In addition, we know that without the execution of this project these controls would have been replaced with Single Phase Controls paired with their corresponding tanks. This substantial cost in future years has been AVOIDED due to the executon of the project.
# of Multiphase Controls Installed 3 Phase Locations	900	
# of Single Phase Controls Replaced at Multiphase Locations	2700	
# of Multiphase Controls Installed 2 Phase Locations	350	
# of Single Phase Controls Replaced at 2 Phase Multiphase Locations	700	
# of Single Phase Controls Replaced at Single Phase locations	1000	
TOTAL # of Single Phase Controls Replaced during the Project	4400	
Average Cost of a Single Phase Control over the next 10 years considering 5% inflation over those years	$7,000	
Current Cost of a Single Phase Reg Control	$6,400	
Average Lifespan of a Regulator Control	20 to 25 years	Reference: Regulator Control Supplier
Total Estimated # of Controls that will fail during a Time Period starting in the year 2027 for the next ten years.		Large Sample Size of 790 were evaluated. Of that sample size 163 were year 2000 or older (pre-2000) representing about 20% overall. So, an extrapolation across the entire population of 4400 Controls results in about 4400 *20% or about 880 Controls that are likely to fail during the 10 year period starting in 2027
Estimated # of Controls that were likely to fail during the time period after completion of the project starting in 2027 over a ten year period	800	
Apply Loading factor of 2.3 assuming these Controls would have been from Stores.	2.3	
Average Annual Rate of Replacement for Reg Controls starting in 2027	10%	
Average Annual Reg Control Replacement Costs starting in 2027	$1,288,000	

Customer Savings (MWh)

Reg-enabled MW Peak Reduction Benefits (MWh)		
Cost/MWh ($)	$32.15	
# of Circuits with CVR (as of 12/31/2024):	430	
2030 # of Circuits	900	
# of CVR circuits with Line Regs:	73	
# of Line Regs supporting CVR:	42	
# of available line regs on CVR circuits:	211	
% of CVR-enabled line regs:	20%	
Expected MWh savings of CVR through 2030 (MWh):	271582	
% of CVR-enabled line regs vs. # of line regs on LVD system:	2%	
Assume 2% support of line regs for expected MWh savings (MWh):	6336.91	Total MWh savings through 2030 (NOT per year)
Assume 2% support of line regs for expected Cost/MWh savings ($):	$203,731.76	Total $ savings through 2030 (NOT per year)
Average Annual Benefit for expected Cost/MWh savings ($):	$18,521.07	

CMI

# of Customers Fleetwide	1,889,301	
Average Length of a Line Regulator Caused Outage (Minutes)	30	
Average # of Customers on an LVD Circuit Outage	151	
Annual Average # of Outages Avoided due to Automatic Preventative Maintenance is equal to the # of Reg Tank Replacements that do not have to happen in a year	13	
Total Average Custimer Minutes Interrupted (CMI) Saved on an Annual Basis	56625

Costs Calculations

Assumptions

Post-Tax WACC (%): 7.25%

		2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036
Capital Spend ($):	$ 15,129,138	$ 8,000,000	$ 7,646,000										
		8000	7646										

The manufacturers date was recorded from the nameplate on the 790 regulator tanks during line regulator deployment activities
This is considered to be a large sample size against a total population of 1800 locations

The large sample size of 790 were evaluated. Of that sample size 163 were year 2000 or older (pre-2000) representing about 20% overall. So, an extrapolation across the entire population of 4000 controls results in about 4000 *20% or about 800 controls that are likely to fail during the 10 year period starting in 2027 based on average lifespan of 20 to 25 years for a regulator control

Here are the numbers associated with the 163 that were year 2000 or older

Time Span	# of Controls
Pre-1990	1
1990-1995	49
1996-2000	113
2001-2005	116
2006-2010	171
2006	35
Other (Remainder)	450
	340
Total Sample Size	790

Consequently, a total of 163 are the year 2000 or older (pre-2000) or about 20% of the total sample size.
163

% of Sample Size 2000 year or older versus the total Sample Size **20.63%**

So this large sample size is likely representative of the total population and we can extrapolate across the entire populuation to determine the age composition of controls across the LVD fleet.

CAPITAL SPENDING ($000)
Project Name: Line Regulator Controller Upgrades

Note: Capital Spending entered below should include any AFUDC. If a project was started in 2025 or before the total spend to date related to the project should be entered into the Balance as of 12/31/2025 (including any AFUDC).

Line No.	(a)	(b)	
1	**Reliability Benefits**	**1,062,438**	**Avoided CMI**
2	**Rate Recovery Costs**	**$ 44,496,963**	

PROJECT ASSUMPTIONS AND DETAILED CALCULATIONS

Assumptions

1889301	**customer population**
60	**average time to visit a site with a crew going into enclosed spaces**
157	**number of vaults today**

Benefits Calculations

Reduce patrol time via not having to check so many device locations in manholes to **validate the state of the system** and location of the fault.

5	average number of switching and tagging points during an incident to validate
60	average length of time to validate a site
300	minutes to validate the state of the system before restoration
30	projected validation minutes in new state
270	minutes of validation saved
1561	customer affected annually
421470	saved customer minutes
0.222	**SAIDI**
0.0014	SAIDI per vault

		2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037
SAIDI	**Sum**	0.0000	0.0028	0.0099	0.0170	0.0240	0.0311	0.0381	0.0452	0.0523	0.0593	0.0664	0.0735

Remote Restoration

this is at the end of each outage incident that we can avoid returning to the open vault/circuit situation because it can be closed in remotely.

1,561	customer affected annually
60	average time it takes to set up for restoration which is being eliminated
93,660	annual minutes saved due to remote restoration
596.56	minutes saved per vault

		2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037
SAIDI	**Sum**	0.0000	0.0006	0.0022	0.0038	0.0054	0.0069	0.0085	0.0101	0.0117	0.0133	0.0148	0.0164

Planned Transfers < instead of sending crews to multiple vaults, execute return to normal switching steps remotely without crew involvement

5	average number of switching and tagging points in a switching order
60	average length of time to validate a site
50	number of switching orders executed in a year
15	time it takes in new state
237.5	saved crew hours per switching order

Public safety/security:

high water alarms to avoid flooding vaults which dump all customers.

historical flooding outage data:

		cust average	min	custmin	
2024	1	87	313	27231	
2021	2	460.5		191000	
2019	3			26112	
				48869	annual flooding outage minutes avoided due to high water sensors/alarms
				311	per vault

	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037
SAIDI	0.00000	0.00033	0.00115	0.00198	0.00280	0.00362	0.00445	0.00527	0.00610	0.00692	0.00774	0.00857

Safety how many people hours of exposure is being eliminated

24	number of outage incidents in 2024
370	number of switching times a vault would be visited
15	average time at a site spent doing the hazardous work associated with entering vaults
2	average number of persons in a crew
185	total people hours of exposure to vaults by crews eliminated
1.18	people hours of exposure per vault

exposure	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037

PROJECT ASSUMPTIONS AND DETAILED CALCULATIONS

Assumptions

	1,889,301	Total Electric Customers
$	440.00	Typical 3 person Elec Dist Crew $/hour (loaded costs)
	15%	Distribution Asset Management Year to Year Improvement %
	5%	Asset Data Quality Beginning Perecentage
	36%	Asset Management System (AMS) maturity %
	3%	Asset Depreciation Improvement value
	85%	% Work Assignned to CE Crews
	15%	% Work Assignned to Contract Crews
$	955.00	Contractor Crew Cost $/hour (direct cost)

	2,295	Five Year Average of Annual Outages per feeder
$	357.29	Average O&M Spend per outage on Feeder
	40%	Avoided Restoration Costs Loading Multiplier
	31%	Overtime %.
	105%	Maturity Cost Adder.
	23,267	Medium & Large C&I customer count

Benefits Calculations

Benefit Calculations are summarized in the "Benefits & Costs Data" worksheet.
The "Benefit Details" worksheet describes the different project impacts on the E
The "Asset Details" worksheet includes asset specific benefit ca
The "Avoided Restoration Costs" worksheet is used to show a multi-year breakdown of avoided restoration c

Line No.	(a)	(b)
1	**Total Reliability Benefits**	**12,575,250**
2	**Rate Recovery Costs**	**$ 4,498,559**

Avoided CMI

PROJECT ASSUMPTIONS AND DETAILED CALCULATIONS

Assumptions

14 Hrs	**Average restoration time for a typical storm (based on 2024 storms)**
82 Hrs	**Average restoration time for a catastrophic storm (based on 2024 catastrophic storms)**
150	**Average # of crews during "Gray Sky" storm**
10	**Estimate of installation time. (2 hours per weather station, total of 45 weather stations per year)**
15	**Average # of "Gray Sky" or Larger storms per year**
25	**Estimate time (hours) for repairs and maintenance**
1,889,301	**Number of electric customers**
18,900	**Amount of customers needed to be without power in order for a "Gray Sky" storm to be declared**

Benefits Calculations

Reliability SAVINGS CALCULATIONS

18,900	**Amount of customers needed to be without powe**
60	**Number of minutes in the average restoration time saved per storm**
15	**Average # of "Gray Sky" or Larger storms per year**
1,889,301	**Number of electric customers**
1/14	**Fraction of the total restoration time being saved (see A10 for average restoration time for typical storm)**
0.64	**Total SAIDI Savings per year**

EXECUTIVE SUMMARY

Conservation Voltage Reduction (CVR) is the practice of reducing service delivery voltage to the lower portion of the acceptable industry range as specified in ANSI Standard C84.1 to reduce energy consumption for waste energy reduction purposes and/or reduce peak electrical demand. Consumers Energy of Jackson, Michigan has conducted a CVR Demonstration Project that included implementing CVR on fifty of its electric distribution feeders that are located throughout the Consumers Energy service territory and has been operating in CVR reduced-voltage mode on alternating days since 2019.

To determine the waste energy and peak demand reduction that can be attributed to voltage reduction, Consumers Energy has conducted a Measurement and Verification (M&V) analysis of the electrical measurement data collected for each of the fifty feeders during the period of CVR alternating-day (aka, "day-on/day-off") operation. This analysis separates the electrical impacts of voltage reduction from other factors that affect the energy consumption and peak electrical demand, such as naturally varying custom behavior and ambient weather conditions, as well as variations in energy consumption for different hours of the day, days of the week, seasons, and other temporal variations.

In January 2021, Consumers Energy hired ESTA International, Ltd. (ESTA), an independent consulting firm specializing in electric utility automation and energy analysis to review and critique the Consumers Energy CVR project and associated M&V analysis performed by Consumers Energy. This report summarizes the results of this assessment.

M&V ASSESSMENT FACTORS

ESTA's assessment of the Consumers Energy CVR M&V approach included the following items:

- Process for Selecting Feeders. Consumers Energy will use the results of the CVR demonstration project to determine whether CVR implementation on additional feeders is justified. Therefore, the 50 feeders selected for the CVR demonstration should have characteristics (customer mix, regional distribution, etc.) that are representative of other Consumers Energy feeders on which CVR may be implemented in the future. Consumers Energy used a two-step process for selecting feeders for the CVR demonstration:

    - During Step 1, Consumers Energy identified 1,700 feeders that are viable candidates for implementing CVR based on factors such as availability of remote-controlled devices and telecommunication facilities. These feeders are labeled the "CVR Proposed" set.

    - During Step 2, Consumers Energy selected 50 feeders from the CVR Proposed set on which to implement CVR for demonstration purposes. In selecting these 50 feeders, preference was given to feeders with characteristics that best match the CVR proposed set. Preference was given to feeders that have a similar mix of residential, commercial and industrial customers.

  The feeder selection process used by Consumers Energy is far more detailed and superior to the selection process used by other utility companies. In ESTA's opinion, the selected CVR feeders are representative of the CVR Proposed set of feeders and, therefore, it is acceptable to assume that similar results will be obtained as CVR is added by Consumers Energy to additional feeders.

- CVR System. The CVR system deployed by Consumers Energy is like most CVR systems that have been deployed in the past 5 to 10 years by other electric utilities. This system applies fixed "rules" that have been predetermined by Engineering to real-time measurements obtained by the Consumers Energy SCADA system to determine what control actions (if any) are needed for switched capacitor banks and voltage

regulators. The CVR system automatically switched between CVR-On mode (reduced voltage) to CVR Off mode (normal voltage) on alternating days. In ESTA's opinion, the rules-based approach is a cost-effective approach that is well suited to the project's "proof of concept" objectives. One shortcoming of this approach is that the system must be disabled for a given feeder if that feeder is reconfigured. This is not a major problem because such reconfiguration is infrequent. However, ESTA recommends a "model-driven" approach to CVR that automatically adapts when feeders are reconfigured. This approach can be implemented on the new Consumers Energy ADMS.

- Controlled Devices: The Consumers Energy CVR system controls switched capacitor banks and voltage regulators as needed to accomplish the CVR objectives. This is consistent with industry practice. Consumers Energy has a significant advantage over many other utility companies because voltage regulation is done on an individual-feeder basis. This enables Consumers Energy to reduce voltage on some feeders even if other feeders fed by the same substation are "voltage limited". In the future, control of other devices such as Distributed Energy Resources (DERs) with "smart inverters", may be required by Consumers Energy. The previously mentioned model-drive solution will be able to handle the addition of such devices.

- Data Collected During the Demonstrations: ESTA reviewed the list of electrical measurements collected during the CVR demonstrations to determine if the measurements taken are sufficient for effective operation of the CVR algorithms and determining the CVR factors. ESTA concludes that the collected data is consistent with the data collected by other utilities and is sufficient for computing the CVR factors for the CVR demonstration feeders. Some "data scrubbing" was performed by Consumers Energy to eliminate data anomalies. However, ESTA notes that the amount of data scrubbing needed by Consumers Energy for its data was much less than the data scrubbing needed by other utilities, indicating that the Consumers Energy data quality, in general, is very good.

- Method of Computing CVR factors for Waste Energy Reduction and Peak Demand Reduction. ESTA reviewed the method used by Consumers Energy to compute the CVR factors. Consumers used a method called "Matching Pairs" to compute a CVR factor, which is an important metric for CVR effectiveness. The Matching Pairs method compares weekday load and voltage measurements with reduced voltage (CVR On days) to weekday measurements when normal voltage normal voltage was applied (CVR Off days). Separate calculations were performed for each season because average ambient temperature can have a significant impact on CVR factor. having similar ambient temperature. The resulting CVR factor for Waste Energy Reduction was 0.82, meaning that when voltage is reduced by 1%, load is reduced by 0.82%. The result is consistent with results obtained by other utility companies, which generally fall in the range of 0.7 to 0.8.

  The most common method used in the industry to calculate CVR factors is multiple regression analysis to determine the impact of ambient temperature, voltage, and other factors on load. To confirm the results obtained by Consumers Energy, ESTA performed an independent calculation of CVR factor using regression analysis on the data supplied by Consumers Energy. The result of this analysis was a CVR factor of 0.77 +/- 3.7%. In ESTA's opinion, the results of this independent calculation confirms the accuracy of the Consumers Energy matching pairs method.

  ESTA also used the regression method to determine a CVR factor for Peak Reduction. The Peak Reduction CVR factor is typically significantly different than the Waster Energy Reduction CVR factor because the equipment complement and consumer appliances are different during peak load conditions than the on-line equipment complement during off peak periods. The results of this analysis is a Peak CVR factor of 1.51 with a model error of +/- 3.89%. ESTA is only aware of one utility (undisclosed) that has published a Peak

Demand CVR factor. The published CVR factor was 1.45, which is comparable the results obtained by ESTA.

Later this year, Consumers Energy is planning to use a load forecasting software tool called "MetrixND" (supplied by ITRON) for computing CVR factors. This software tool uses regression analysis to estimate what the load "would have been" with normal voltage for a given day of week an average ambient temperature. ESTA strongly recommends using this type of analysis for determining CVR factors.

CONCLUSIONS

For reasons given above, ESTA concludes that the CVR system software and hardware are well-suited and adequate for conducting the CVR demonstration and that the results obtained for the 50-feeder demonstration can be applied to other Consumers Energy feeders. While the "Matching Pairs" method used by Consumers Energy for computing CVR factor is somewhat unique, the results obtained using this approach match the independent calculations performed by ESTA reasonably well.

Going forward, ESTA encourages Consumers Energy to implement the MetrixND method, not only for estimating peak demand reduction but also for distribution load forecasting in general. ESTA also recommends that Consumers Energy implement a model-driven, ADMS-based approach to CVR because this approach has operational advantages described in this report.

1 INTRODUCTION

Conservation Voltage Reduction (CVR) is the practice of reducing service delivery voltage to the lower portion of the acceptable industry range as specified in ANSI Standard C84.1 to reduce energy consumption for waste energy reduction purposes and/or reduce peak electrical demand. Consumers Energy of Jackson, Michigan has conducted a CVR Demonstration Project that included implementing CVR on fifty of its electric distribution feeders that are located throughout the Consumers Energy service territory and has been operating in CVR reduced-voltage mode on alternating days since 2019.

To determine the waste energy and peak demand reduction that can be attributed to voltage reduction, Consumers Energy has conducted a Measurement and Verification (M&V) analysis of the electrical measurement data collected for each of the fifty feeders during the period of CVR alternating-day (aka, “day-on/day-off”) operation. This analysis separates the electrical impacts of voltage reduction from other factors that affect the energy consumption and peak electrical demand, such as naturally varying custom behavior and ambient weather conditions, as well as variations in energy consumption for different hours of the day, days of the week, seasons, and other temporal variations.

The results of the CVR M&V analysis conducted by Consumers Energy indicate that the CVR factor, an important metric for measuring the load-to-voltage sensitivity, ranges from 0.07 to 1.34 for the 50 feeders that Consumers Energy has analyzed. This means that reducing the voltage applied to these electric distribution feeders by 1% will reduce electrical demand on these feeders by between 0.07% and 1.34% without any adverse electrical impacts or load shedding by Consumers Energy customers. The average CVR factor for the 50 CVR circuits is 0.82, which is consistent with CVR factors reported by other electric distribution utilities that have implemented CVR.

Consumers Energy is seeking an independent assessment of its CVR efforts to verify the results to date and assist Consumers Energy in determining whether implementing CVR on additional feeders would be beneficial to Consumers Energy and its customers. In January 2021, Consumers Energy hired ESTA International, Ltd. (ESTA), an independent consulting firm specializing in electric utility automation and energy analysis to review and critique the Consumers Energy CVR project and associated M&V analysis performed by Consumers Energy. This report summarizes the results of this assessment.

2 SCOPE OF THE INDEPENDENT CVR ASSESSMENT

The objective of the consulting assignment is to review and critique the methods used by Consumers Energy to conduct the Day-On/Day-Off CVR demonstration and to assess the method used to analyze the resulting data to determine the CVR factor, which is an important performance metric for CVR. ESTA's assessment included the following items:

- Process for Selecting Feeders. ESTA reviewed and critiqued the method Consumers Energy used to select the feeders on which the CVR demonstration was performed. Ideally, the selected feeders are representative of Consumers Energy feeders where it is practical and economical to implement CVR. That is, the selected feeders should have characteristics that are like the characteristics of the larger set of feeders on which CVR could be implemented. Such characteristics included (but were not limited to) feeder length and configuration, customer mix (residential, commercial, industrial), and location (North, South, East, West).

- CVR Software Algorithms. ESTA reviewed the algorithms and principles of operation of the CVR application software (furnished by the Consumers Energy Distribution Management System (DMS) supplier OSI International (OSII)) to gain a thorough understanding of the approaches used for 24-hour-a-day energy conservation and peak demand reduction.

- Controlled Devices: ESTA reviewed the list of devices that are controlled by the CVR application software, such as feeder voltage regulators and switched feeder capacitor banks. The feeders in question do not include significant penetrations of Distributed Energy Resources (DERs) such as rooftop solar photovoltaic generators which can affect the distribution feeder voltage and reduce the "net" load measured on the feeder. Hence, the DER impact on the results of this study are not significant.

- Data Collected During the Demonstrations: ESTA reviewed the list of electrical measurements collected during the CVR demonstrations to determine if the measurements taken are sufficient for effective operation of the CVR algorithms and determining the CVR factors. ESTA also reviewed the methods used for "data scrubbing" that is needed to eliminate data anomalies, such as bad and missing data, that may produce incorrect results.

- Method of Computing CVR factors for Waste Energy Reduction and Peak Demand Reduction. ESTA reviewed the method used by Consumers Energy to compute the CVR factors. The objective of this activity was to determine if the analytical methods are accurate and consistent with establish industry practices. ESTA compared the Consumers Energy methodology with the analytical approaches described in IEEE Standard 1885: "Guide for Assessing, Measuring and Verifying Volt-Var Control Optimization on Distribution Systems" to ensure consistency with this standard.

ESTA compared the Consumers Energy approach for each of the items listed above against the approach used by other electric distribution utilities that have similar characteristics to Consumers Energy and have already implemented CVR to determine if the Consumers Energy approach is consistent with best industry practices.

In addition to the assessment of Consumers Energy CVR M&V strategy described above, the project also includes developing a mechanism for predicting what CVR factor would be achieved by implementing CVR on additional feeders. This mechanism is described later in a separate report.

3 QUALIFICATIONS OF ESTA FOR PERFORMING THIS ASSESSMENT

ESTA is uniquely qualified for performing this assessment of Consumers Energy CVR projects and results for reasons stated below:

- ESTA has recently completed a detailed M&V assessment of CVR for Consolidated Edison of New York and has also conducted similar assessments for other utility companies that are similar in size and electrical characteristics to Consumers Energy.

- ESTA's team lead, Mr. Robert Uluski, has served as Chair of the IEEE's Power and Energy Society Task Force on Volt-VAR control and optimization and played a lead role in developing IEEE Standard 1885: "Guide for Assessing, Measuring and Verifying Volt-Var Control Optimization on Distribution Systems". This standard identifies ways in which electric distribution utilities can evaluate the CVR benefits. This standard was recently approved and published by IEEE. Mr. Uluski has also managed EPRI's "Smart Distribution" research program that included extensive work in laboratory testing to identify load-voltage sensitivity of major electrical appliances and equipment and in load-voltage modelling.

- ESTA's energy analyst, Mr. Spandan Gandhi, has considerable experience in advanced techniques for CVR M&V, including use of neural nets and multiple-regression analysis for modelling and analyzing the impacts of voltage reduction, as well as data scrubbing to identify data anomalies that can distort the M&V results.

- ESTA is a fully independent consulting firm that has no relationships with any system vendor and no vested interest in any commercial product. As a result, our findings, conclusions, and recommendations are completely unbiased by any such relationships.

4 LIST OF ACRONYMS

Following is a list of acronyms and key terms used in this report.

Table 4-1 List of Acronyms

Acronym/ term	Description
AMI	**Advanced Metering Infrastructure -** Facilities for periodically measuring and reporting customer electrical consumption at intervals of an hour or less for billing purposes, and for determining customer consumption patterns. AMI outputs in the form of "last gasp" messages have become a commonly-used mechanism for detecting power outages at individual customer sites. AMI may also be used for detecting low or high voltage conditions and the customer meter and reporting such conditions to the system operator and other persons responsible for outage management.
ANSI	**American National Standards Institute** - a private, non-profit organization that administers and coordinates the U.S. voluntary standards such as C48.1 ("Electric Power Systems Voltage Ratings")
CVR	**Conservation Voltage Reduction** - the process of intentionally reducing the voltage on a distribution circuit to the lower portion of the acceptable voltage range permitted by ANSI standard C84.1.
Day-On/Day-Off	A process of activating a system (such as CVR) on alternating days, and comparing measurements recorded during the "system on" day versus the "system off" day. of comparing
DER	**Distributed Energy Resource -** small scale generators, energy storage units, and controllable loads that are connected to the electric distribution system in close proximity to the load centers. DERs are most commonly used today to supply real and reactive power and curtail load when needed, the objective being to lower dependence on large scale centralized generators and high voltage transmission line as the sole source of supply. In addition, some DERs, such as solar and wind power are renewable energy sources that can help lower greenhouse gas emissions.
DMS	**Distribution Management System** - a computer and communication system the enables electric distribution system operators to monitor and control the distribution system assets and overall electric distribution system performance from the distribution control center.
DR	**Demand Reduction -** a set of processes used to curtail electrical consumption during system emergencies.
DSCADA	**Distribution Supervisory Control and Data Acquisition -** a computer and communication system that enables distribution system operators to monitor and control electric system power apparatus from a control center. The SCADA system is a fully integrated element of the Consumers Energy DMS.
EPRI	**Electric Power Research Institute -** an American independent, nonprofit organization that conducts research and development related to the generation, delivery, and use of electricity to help address challenges in electricity, including reliability, efficiency, affordability, health, safety, and the environment.
ESTA	**ESTA International, Ltd** - an independent consulting firm specializing in the planning, implementation, and the post-implementation analysis of benefits associated with electric utility automation systems. Consumers Energy hired ESTA to perform an independent assessment of its CVR system.

IEEE	**Institute of Electrical and Electronic Engineers -** a large worldwide professional association for electronic engineering and electrical engineering. IEEE is one of several recognized standards-making bodies for electric power systems.
kVAR	**Kilo-volt-ampere-reactive -** A measure of reactive power
LTC	**Load Tap Changer -** A device that automatically regulates the voltage supplied by a substation transformer to the electric distribution feeders. Note that Consumers Energy uses voltage regulators on individual feeders and does not use LTCs.
M&V	**Measurement and Verification** - the process of using measurements to determine actual savings created within an individual facility by an energy management, energy conservation or energy efficiency project or program. M&V is commonly used for estimating the benefits that cannot be measured directly, such as CVR benefits.
OSII	**Open Systems International, Inc, -** the system vendor that supplied the Consumers Energy ADMS that is used to implement CVR.
VVO	**Volt-VAR Optimization -** A software application running on the DMS for improving the efficiency and voltage quality on the electric distribution system. CVR is a subfunction of VVO.

5 ESTA ASSESSMENT OF CONSUMERS ENERGY CVR PROGRAM AND M&V APPROACH

ESTA's assessment of each of the items related to Consumers Energy CVR program is contained in the following sections. The following items are included:

1. Feeder Selection
2. CVR Software Algorithms
3. Controlled Devices
4. Data Collection
5. Method of Computing CVR factor

For each of the items listed above, ESTA has provided the following information:

a) General requirements pertaining to each item.
b) ESTA's understanding of the Consumers Energy approach for each item.
c) Comparison of Consumers Energy approach to best industry practices.
d) ESTA's Findings, conclusions, and overall assessment of Consumers Energy approach to each item.

5.1 FEEDERS SELECTED FOR CVR IMPLEMENTATION

The purpose of this section is to determine if the CVR benefit results for subset of feeders selected for this CVR demonstration project are representative of the CVR benefits that could be gained by implementing CVR on additional feeders.

a) General Requirements and Industry Practice for Feeder Selection

- Feeders should not be "voltage limited". If the service delivery voltage on a given feeder is near the low limit specified in ANSI standard C84.1 at one or more feeder locations during some loading conditions, it may not be possible to reduce voltage when needed. Feeder infrastructure improvements (reconductoring, etc.) may be needed to "flatten" the voltage profile on voltage-limited feeders and provide a suitable operating margin for voltage reduction.

- The customer mix (percentages of residential, commercial, and industrial customers) served by the feeder should be representative of the typical customer mix on other Consumers Energy feeders. Consumers Energy should not select a feeder that has a unique customer mix because results for that feeder may not be indicative of results that may be obtained on other Consumers Energy feeders.

- Voltage and VAR control devices on the feeder should be equipped with remote control capabilities that are needed for the Consumers Energy CVR system (see Section 5.2 for a description of the Consumers Energy CVR system).

- Feeders should have a suitable mechanism for determining the lowest voltage on the feeder. This will provide feedback to the CVR software to ensure voltage is not reduced below the low voltage limit specified in the ANSI standard.

- The feeders selected for CVR demonstration should be widely dispersed throughout the Consumers Energy service territory because the results for feeders in different geographic regions may be different. For example, the results for feeders in the Northern portion of the state may differ from feeders in the Southern portion of the state due to different energy consumption for heating and cooling in these two regions.

b) ESTA's Understanding of the Consumers Energy Approach to Feeder Selection

Consumers Energy used a two-step process for selecting feeders on which to implement CVR during the CVR demonstration project, as described below:

1. During step one of this process, Consumers Energy created a "CVR Potential" circuit pool consisting of approximately 1,700 distribution feeders that are viable "candidates" for CVR implementation. Feeders with the following characteristics were selected for the CVR Potential circuit pool:

    i. Feeder has substation DSCADA telemetry to enable remote monitoring and control capabilities. The Consumers Energy CVR system requires near-real-time DSCADA measurement data, such as reactive power flow, to determine if feeder capacitor bank switching is required. In addition, the CVR Potential circuits must have upgraded line voltage regulators that can be monitored and controlled by DSCADA and the CVR system

    ii. Circuit is not a Dedicated-Customer circuit. Most dedicated customer circuits have unique loading characteristics so the results would not be representative of other Consumers Energy circuits.

    iii. The circuit is not supplied by a delta (3-wire) substation. There are relatively few delta circuits at Consumers Energy, so the CVR results for this type of feeder would not be representative. In addition, the CVR control logic would be more complicated than wye-grounded (4-wire) circuits.

    iv. At least 50% of the customers on the feeder are residential customers. Circuits that primarily serve Commercial and Industrial customers (i.e., % of C/I customers greater than 66%) were excluded from the CVR potential circuits. Feeders with a proportionately higher number of residential customers is common at Consumers Energy, so circuits that serve a high percentage of residential customers are more representative of Consumers Energy distribution feeders.

2. During step 2 of the selection process, Consumers Energy selected 50 of the CVR Potential feeders with characteristics that are most representative of the total set of CVR Potential distribution feeders. Factors considered in selecting the 50 CVR feeders from the CVR Potential list of feeders included customer type breakdown, Archetype, circuit length, customer count, and the percentage of residential customer. ESTA's assessment of each of these feeder selection criteria is provided below:

a) **Customer Type Breakdown:** Customer type breakdown (or the percentages of residential, commercial, and industrial customers on a given feeder) is the primary factor used by Consumers Energy in selecting the CVR feeders from the CVR Potential list. The CVR factor is primarily impacted by the types of customers served by the feeder and the complement of electrical equipment and appliances used by these customers. Therefore, selecting feeders with customer type breakdown that matches the CVR Potential Set is critical for identifying representative feeders for CVR deployment. ESTA computed the customer type breakdown of feeders that were selected for CVR and the CVR Potential group. As seen in below, the differences in percentage mix of customers in the selected set and the CVR Potential set are very small. Therefore, ESTA concludes that the selected CVR circuits are representative of the Consumers Energy CVR potential feeders.

Table 5-1 Comparison by Customer Type Breakdown

	Customer Type Breakdown		
Customer Type	CVR Potential	CVR Selected	Difference
% Commercial	13.3%	11.5%	1.8%
% Industrial	0.2%	0.1%	0.1%
% Residential	84.8%	86.9%	-2.1%

b) **Archetype:** ESTA compared the Archetype breakdown for the selected CVR circuits with the Archetype breakdown for the CVR Potential group, as shown below. The breakdown of feeders by Archetype in the selected CVR set of feeders differs from the CVP Potential set by between 0% and 9%. The most significant difference is that a higher percentage of urban circuits (Archetypes 3 and 4) was selected over rural circuits (Archetypes 5, 6, and 7). In ESTA's opinion, the choice of urban feeders over rural feeders is justified, because urban feeders usually provide higher overall CVR benefits than rural circuits due to shorter length (less voltage drop) and heavier loading (more kWh reduction per unit voltage reduction). ESTA also believes, based on industry experience, that the percentages of rural feeders in the CVR Potential set are too high and that it is unlikely the Consumers Energy would actually add CVR to such a high number of rural circuits due to the lower payback opportunity.

Table 5-2 Comparison by Archetype

Archetype	Archetype Description	CVR Potential	CVR Selected	Difference
0	Circuit has not been assigned an Archetype Value yet	1%	0%	1%
1	Most Large C&I customers, short circuits that are primarily underground, best reliability	2%	25	0%
2	Circuits with greatest mix of customers and high proportion of small C&I, moderate reliability	11%	16%	-5%
3	Urban residential customers, short lines with high customer density, strong reliability, high NPS	14%	18%	-4%
4	Urban customers, longer circuits with high customer density that are more susceptible to outages	27%	36%	-9%
5	Rural circuits primarily in central/south, better reliability than rural circuit peers	20%	12%	8%

6	Rural circuits, low customers per line mile, high frequency of outages and long outage durations	15%	12%	3%
7	Rural customers primarily in the north, longest circuits, worst reliability across the system	10%	4%	6%
8	Radial, unshielded, higher risk HVD groups	0%	0%	0%
9	Core, looped HVD system	0%	0%	0%

c) **Circuit Length:** In general, circuit length does not have a significant impact on the CVR factor. However, since longer feeders will experience a greater voltage drop over the length of the feeder, feeder length impacts the percent voltage reduction that is possible, and therefore, impacts the CVR benefit (lower energy savings and smaller peak shaving possible). Table 5-3 shows the length breakdown of feeders in the selected CVR set of feeders and the CVR Potential circuits. As can be seen in the table, the selected CVR feeder set has a significantly higher percentage of shorter feeders than the CVR Potential set. In ESTA's opinion, this difference is not a matter of concern when computing CVR factor, because, as stated above, feeder length by itself does not impact CVR factor.

Table 5-3 Comparison by Feeder Length

Feeder length (Miles)	CVR Potential	CVR Selected	Difference
0-10	18.6%	40.0%	-21.4%
10-25	31.3%	24.0%	7.3%
25-40	19.2%	24.0%	-4.8%
40-55	14.1%	4.0%	10.1%
56+	16.8%	8.0%	8.8%

d) **Residential Percentage:** ESTA compared the residential percentages in the selected CVR circuits with the residential percentages in the CVR Potential circuit pool. As can be seen in this table, the percentage of residential customers matches reasonably well between the selected CVR circuits and the CVR Potential circuits except for circuits where the percentage of residential customers is less than 80%. Since the Consumer Energy focus is on feeders that have a high percentage of residential customers, this difference should not be a significant problem. Hence, ESTA concludes that here is a good match in residential customer percentages between to the two sets of circuits.

Table 5-4 Comparison by Residential Percentage

% Residential	CVR Potential	CVR Selected	Difference
0-80%	19.4%	8.0%	10.6%
80-85%	19.5%	24.0%	-4.5%
85-90%	30.9%	36.0%	-5.1%
90-100%	30.2%	32.0%	-1.8%

e) Customer Count: As can be seen in Table 5-5, the breakdown of total customer count for the selected feeders matches very well with the breakdown of customer count for the CVR Potential circuits.

Table 5-5 Comparison by Customer Count

Customer Count	CVR Potential	CVR Selected	Difference
0-500	17.7%	18.0%	-0.3%
501-1000	34.2%	32.0%	2.2%
1001-1500	26.6%	24.0%	2.6%
>1500	21.5%	26.0%	-4.5%

f) Other comparisons

- **Region:** Feeder location can have a significant impact on CVR factor, especially for circuits that are in the Northern versus Southern portions of the State of Michigan. The latitude and longitude of the selected CVR circuits is consistent with the Potential CVR circuit pool. The feeders in both the circuit pool and the selected set are primarily located in the southern and central part of the State, with a few outliers in the North. Both sets appear to be split equally between substations in the Eastern and Western parts of the State. Note that the North and south difference is more significant when computing a CVR factor, because energy consumption patterns and associated CVR factors may be different for northern (colder) regions and southern (warmer) regions of the state.

c) **Comparison of Consumers Energy approach to best industry practices**

Several other factors may be considered when selecting circuits for CVR:

a. **Worst performing feeders:** Some utilities have elected to implement CVR (and the broader application Volt-VAR Optimization) on circuits that have historically experienced low power factor. The VVO application can improve power factor and thus reduce losses on these worst performing feeders in addition to accomplishing peak shaving and energy conservation using CVR.

b. **Heavily Loaded Circuits:** Heavily loaded circuits are often selected (provided they are not voltage limited) because the energy savings and peak shaving benefits for a given amount of voltage reduction are greater for a given circuit than a lightly loaded feeder having the same CVR factor.

c. **Groups of Feeders from Same Substation:** Groups of feeders fed off the same substation bus are usually selected for CVR at the same time. This is because voltage reduction actions are performed by a substation load tap changer (LTC) transformer which impacts all feeders that are connected to the low side bus of the transformer. This does not apply to Consumers Energy, which uses individual feeder voltage regulators.

d) **Findings, conclusions, and overall assessment of Consumers Energy approach**

In ESTA's opinion, the process used by Consumers Energy for selecting feeders for its CVR demonstration far exceeds the feeder selection process used by other utilities that have demonstrated and/or implemented CVR. Most utilities have selected feeders based on a limited set of factors such as the availability of DSCADA and remotely controllable volt-VAR devices (feeder capacitor banks and voltage regulators).

Based on the analysis described above, ESTA concludes that the feeders that have been selected by Consumers Energy for CVR are representative of the broader set of CVR Potential feeders. This conclusion is based primarily on the customer type breakdown which matches well between the two groups of feeders. While there are some differences in other selection criteria between the selected CVR circuits and the CVR Potential group of feeders, these factors in general should not have a major impact on the overall CVR factors.

In the case of Archetype differences between the two sets of feeders, ESTA concludes this is due to having too many rural feeders in the CVR Potential set. If the percentages of rural feeders in the CVR Potential set are reduced, the two sets would have comparable breakdowns by Archetype.

As a result, it is reasonable to conclude that the CVR factors computed for the selected feeders are representative of the results that will be obtained if CVR is applied to other circuits in the CVR Potential circuit pool.

5.2 CVR SOFTWARE ALGORITHMS

In this section, ESTA compared the Consumers Energy CVR system with CVR systems that are that have been implemented by other utilities in North America.

a) General Requirements

a. The CVR system should be able to lower the voltage on selected distribution feeders by a Consumers Energy-specified amount to achieve a reduction in waste energy and/or peak electrical demand.

b. A suitable mechanism should be provided to ensure that the service delivery voltage at all customer meters on the feeder does not go below the limits specified in applicable ANSI standards when CVR is activated. CVR must be transparent to the consumers and must not adversely impact the operation of customer-owned equipment.

c. The CVR system shall be able to operate in either of the following Consumers Energy-selectable modes:
    i. Energy Waste Reduction mode: In this mode, voltage shall be reduced by the specified amount whenever possible, up to 24 hours per day. The objective of this mode is to reduce energy (MWh) consumption without customer load shedding for overall efficiency improvement.

ii. Peak Demand Reduction mode: In Peak Demand Reduction mode, the voltage is lowered for a few hours during which peak demand occurs, with normal voltage applied during other hours. For example, if peak load occurs at 5:00 PM, voltage may be reduced between 4:00PM and 6:00PM, with normal voltage being applied during other hours. The objective of this mode of operation is to reduce the maximum load in megawatts on the feeder. The Peak Demand Reduction algorithms shall ensure that restoration of normal voltage following the CVR peak shaving event does not create a new peak; this can happen when diversity of thermostat-controlled devices is diminished during the voltage reduction period.

d. The CVR algorithms shall ensure that voltage and VAR control devices are properly time coordinated so that "hunting" and contradicting control actions are avoided. For example, control actions by voltage regulators to lower the feeder voltage should not be immediately followed by switched capacitor banks operating to raise the voltage.

e. The CVR algorithms shall not initiate improper or invalid voltage control and VAR control commands when the feeder is reconfigured. Feeder reconfiguration can change the position of capacitor banks and midline voltage regulators relative to the power source which, in turn, can result in improper coordination between devices. Furthermore, CVR shall not attempt to control any switched capacitor bank, voltage regulator, or other VVC device that is tagged out of service.

f. The control strategy for volt-VAR devices shall respect device operating restrictions, such as capacitor bank closing within the capacitor bank discharge time and prevention of "local" regulator over-voltages ("first house" protection).

g. The system shall include mechanisms for monitoring the operation of individual capacitor banks, voltage regulators, controllers, and communication facilities and shall be able to detect failures in any of these components that would prevent the device from operating as needed upon command. Failed components should be excluded from the CVR control strategy.

b) ESTA's understanding of the Consumers Energy approach

a. The Consumers Energy CVR approach is best described as a "rules-based" approach. That is, the CVR logic compares SCADA measurements against predetermined setpoints and then initiates control actions based on "if-then-else" rules. For example, if the reactive power flow to the feeder exceeds a specified setpoint, then switch a capacitor bank on the feeder to the "ON" position; otherwise do nothing. Figure 5-1 depicts a SCADA rules-based solution such as that used by Consumers Energy. Simply stated, when reactive power flow measured at the substation end of the feeder exceeds a pre-determined threshold, the CVR system sends commands to one or more capacitor bank switches, which, in turn, reduces the reactive power flow from the substation.

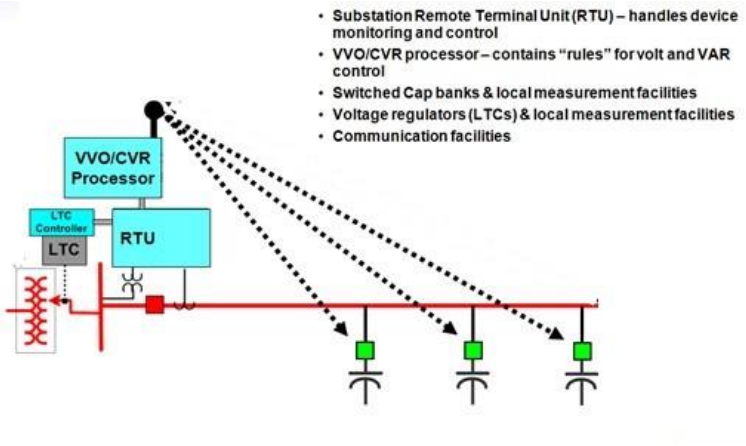

Figure 5-1 SCADA Rules Based CVR System

b. The CVR system setpoints and operating strategies that have been incorporated in the CVR logic have been determined in advance for each feeder by the Consumers Energy Distribution Engineering group using power flow analysis. These setpoints and control strategies have considered "worst case" (e.g., heavy load) conditions to ensure that the recommended CVR control actions will not produce unacceptable, adverse electrical conditions (low or high voltage, equipment overloads, etc.).

c. CVR is currently configured (for demonstration and M&V purposes) to run on alternate days (also known as Day-On/Day-Off strategy). Each day at approximately midnight, the CVR system automatically switches to the opposite operating mode (reduced voltage mode to normal voltage mode or normal voltage mode to reduced voltage mode).

d. To provide proper time coordination of voltage regulators and capacitor banks and avoid "hunting", Consumers Energy has incorporated the following rules in its CVR system:

i. Capacitor banks are controlled first, followed by voltage regulators.

ii. Device coordination is accomplished using different pre-determined time delays on each device.

iii. Capacitor banks that are closest to the load center (i.e., furthest from the source) are switched on first. This allows upstream capacitor banks to see the change in reactive power flow caused by downstream capacitor banks switching before operating to prevent overcompensation.

iv. Voltage regulator control actions (raise or lower tap position) are first executed on substation voltage regulators, followed by the control of midline voltage regulators.

e. Capacitor bank switching is initiated by the CVR software whenever the reactive power flow measured at the substation end of the feeder exceeds a predetermined amount (typically set at +/-

400 kVAR). The CVR system selects the capacitor bank that is closest to the load center (furthest from the substation) whose size in kVAR does not exceed the measured amount. After this capacitor bank is switched, the logic is repeated until no additional capacitor bank switching is possible.

f. If the measured VAR flow at the substation end of the feeder becomes negative (reactive power flow back into the substation (i.e., leading power factor)), the CVR software will switch off capacitor banks using similar logic to that described above (i.e., largest capacitor banks that are closest to the load center switched off first).

g. After a predetermined delay to allow capacitor bank switching to complete, voltage regulator operation is permitted using the predetermined Energy Waste Reduction settings. If midline voltage regulators are present, the time delay for these voltage regulators will be larger than the time delay for the substation voltage regulator for proper time coordination of substation and midline devices.

h. Peak Demand reduction is activated manually by the Distribution Operator during periods when peak shaving is required, such as during Merchant Operations demand reduction (DR) events. The logic used by Peak Demand Reduction CVR logic for controlling capacitor banks and voltage regulators is the same as Energy Waste Reduction. However, the logic is triggered at the start of the event (an hour or two before the system peak) and returned to normal an hour or two following the system peak.

i. If the feeder is reconfigured for any reason, the CVR logic is disabled to avoid switching capacitor banks that are no longer connected to its normal feeder and to avoid improper time coordination due to having a different location of a device relative to its source. It is not practical to incorporate additional rules to handle all the possible switching combinations using simple Boolean logic, and maintenance of such complex logic would be labor intensive. When the CVR system is disabled, the distribution voltage and reactive power control strategy reverts to local autonomous control performed by the individual device controllers.

j. Customer voltages reported by the Consumers Energy Advanced Metering Infrastructure (AMI) are checked the following day to determine if any low or high voltage deviations occurred during the previous day's voltage reduction actions. If frequent voltage deviations are observed for a given customer meter or location, the voltage regulator and capacitor banks settings for the associated feeder are adjusted as needed to avoid reoccurrence of these deviations. If necessary, feeder infrastructure improvements (e.g., reconductoring) may be implemented to eliminate significant voltage deviations that cannot be mitigated by setting changes alone.

c) Comparison of Consumers Energy approach to best industry practices

a. Most of the existing CVR solutions that today's electric utilities have implemented are SCADA "rule-based" systems that use logic like the Consumers Energy CVR system. That is, control decisions are based on "if-then-else" (Boolean) logic performed on measurements received from the utility's distribution SCADA system.

b. Some utilities use proprietary CVR solutions offered by vendors such as Utilidata, Dominion Voltage, Eaton IVVC, and other system vendors. These proprietary solutions are often considerably more expensive per substation then SCADA rules-based solutions due to the sophisticated algorithms and additional hardware needed to identify and implement required control actions. Incremental benefits offered by these systems include the potential for fewer voltage regulator tap position changes and nearly-real-time voltage feedback from strategic feeder locations for rapid detection and correction of voltage deviations. Note that the solution type does not impact the CVR factor, which is determined primarily by the electrical equipment and appliances used on a feeder. Like the Consumers Energy system, these proprietary solutions are often switched off when feeder reconfiguration occurs.

c. A growing trend is the deployment of "model-driven" Volt-VAR Optimization (VVO) solutions that are incorporated in the electric utility's Advanced Distribution Management System (ADMS). These ADMS solutions perform power flow analysis on an as-switched (as operated) electrical model to determine the "optimal" set of voltage and reactive power control actions to achieve one or more selected operating objectives. Selectable operating objectives may include reduce losses, conserve energy, peak shaving, voltage profile improvement, reactive power support to the bulk power grid, minimize use of high maintenance equipment, or a weighted combination of the above. Besides providing selectable business objectives, model driven solutions can provide the following additional benefits:

    i. The power flow solution automatically provides supplies continuous feedback about the voltage at all points on the feeder so that low or high voltage conditions are rapidly detected and corrected.

    ii. Model-driven solutions adapt automatically when feeder reconfiguration occurs so that CVR does not have to be shut down. While the results for a reconfigured feeder may not represent "optimal" results, they do provide the best possible CVR solution with no voltage deviations given the current as-switched condition of the feeder.

    iii. Model driven solutions are better able to accommodate the impacts of distributed energy resources (DERs) and, where possible, leverage the opportunities offered by DERs, such as using "smart" inverters to supply reactive power. Currently, the DER penetration level is not high enough to warrant consideration of these devices in the CVR system. However, if penetration level rises in the future, a model-driven strategy may be the most effective approach.

    The benefits listed above come at a high price (including implementation costs and O&M costs). However, since Consumers Energy is currently implementing an ADMS that will have the necessary model and application software, a cost-effective model-driven solution may be possible Consumers Energy in the future.

d) Findings, conclusions, and overall assessment of Consumers Energy approach

a. The Consumers Energy SCADA rules-based approach is a very effective solution that has achieved significant Waste Energy Reduction benefits and Peak Demand reductions benefits for Consumers Energy customers and Consumers Energy itself at a reasonable cost.

b. The rules-based approach is well-suited for "proof of concept" as well as achieving actual operational benefits.

c. As discussed above, there are two significant limitations of the rules-based approach used by Consumers Energy: inability to handle feeder reconfiguration and lack of immediate voltage feedback when low voltage conditions occur at some customer meters.

    i. In the future, feeder reconfiguration may occur more frequently than before as Consumers Energy introduces new ADMS applications, such as Fault Location, Isolation, and Service Restoration (FLISR). ESTA assumes that when a feeder is reconfigured for any reason, Consumers Energy will endeavor to restore the feeder to its normal configuration as soon as possible. Therefore, the period that CVR will be disabled is minimized. However, in the long run, Consumers Energy should consider implementing CVR on its new ADMS to avoid a complete shutdown of the CVR application when feeder reconfiguration occurs.

    ii. Due to the lack of near-real-time voltage feedback, a small number of customers may at times experience voltage at the low end of the standard voltage range. Such rare voltage deviations are detected manually by reviewing AMI data the day after a voltage reduction event. Upon detecting the problem, Consumers Energy may alter the CVR settings and, if necessary, plan for infrastructure improvements for more serious and severe problems. This method of low voltage detection is acceptable if the voltage deviation is infrequent, relatively small (less than 2-3% below the minimum voltage) and is promptly corrected. However, failure to deal with severe low voltage conditions on a timely basis can result in customer voltage complaints and, in the worst case, damage to customer-owned equipment.

    This problem can be addressed by adding bellwether voltage meters at feeder extremities and other strategic locations and incorporating measurements from these meters in the CVR logic. This is shown in Figure 5-2 below. If possible, near-real-time low voltage alarms from AMI meters can also be incorporated in the logic. The ADMS model-driven solution provides another possible remedy because the ADMS Powerflow computes the voltage at all feeder locations on a continuous basis and will automatically block control actions that would produce voltage deviations.

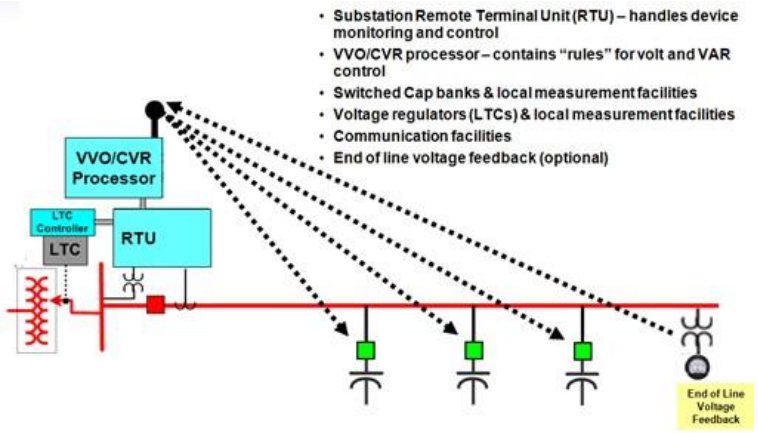

Figure 5-2 Rules-Based CVR with Voltage Feedback

Note that having continuous feedback on feeder voltage level will enable Consumers Energy to operate with a smaller voltage margin to the low voltage threshold, thus enabling Consumers Energy to obtain greater Waste Reduction and Peak Demand reduction benefits.

5.3 CONTROLLED DEVICES

This section contains an assessment of the devices controlled by the Consumers Energy CVR system.

a) General Requirements

The CVR solution should be able to manage the operation of all controllable devices that affect the reactive power flow and voltage profile on the feeder. Controlled devices should include (as a minimum):

i. Voltage regulators located at the head end of the feeder and at mid-line locations (Consumers Energy has few midline regulators on its distribution system and none of these devices on the CVR demonstration feeders)

ii. All switched capacitor banks located out on the feeders.

In the future, the CVR system may need to control additional devices:

iii. ""Edge of network" devices (if any) such as smart inverters and distributed VAR sources located on the secondary side of distribution service transformers.

iv. Distributed energy resources (energy storage, distributed generators with smart inverters, etc.) that are capable of supplying or absorbing real and reactive power on demand.

b) ESTA's understanding of the Consumers Energy approach

a. Consumers Energy CVR system manages the operation of distribution voltage regulators and switched capacitor banks that are installed on the electric distribution system.

b. There are no "Edge of Network" or controllable DERs that are connected to the electric distribution system.

c. Consumers Energy uses separate voltage regulators on all individual feeders. This provides a significant advantage over most other utilities that have multiple feeders connected to a common voltage-controlled substation bus. Consumers Energy can implement different control actions as needed on all feeders out of a single substation without being concerned that a CVR control action will benefit one feeder and adversely impact another feeder that is connected to the same substation. For example, if one substation feeder is voltage limited, it would not be possible to lower the voltage on the remaining feeders connected to the same bus. However, with individual feeder voltage controls, it is possible to lower voltage on feeders that are not voltage limited while retaining the normal voltage or boosting the voltage on the feeder that is voltage limited.

c) Comparison of Consumers Energy approach to best industry practices

The list of controllable volt-VAR devices by Consumers Energy is consistent with devices that are installed on most electric distribution circuits operated by electric distribution utilities.

d) **Findings, conclusions, and overall assessment of Consumers Energy approach**

a. The list of controllable volt-VAR devices on Consumers Energy distribution feeders meets and, in some ways (e.g., control of voltage on individual feeder voltages), exceeds the control requirements for CVR.

b. While Consumers Energy does not currently have any "edge of network" devices, it should be possible to add these devices in the future to either a rules-based solution or ADMS model-driven solution, if needs arise (e.g., widespread electric vehicle charger deployment, addition of significant penetration of rooftop solar PV generators).

5.4 MEASUREMENT DATA COLLECTED

a) General Requirements

a. The CVR system should acquire key measurement data and equipment status information via distribution SCADA or other mechanism on a continuous "near-real-time" basis. In other words, up-to-date field information should be supplied to the CVR system at least once every 15 minutes.

b. Information supplied to the CVR system should include (as a minimum):

i. Real and reactive power flow (A, B, and C phases) measured at the substation end of the feeder.

ii. Voltage measurements (A, B, C phases) at the substation end of the feeder

iii. Voltage measurement at strategic locations on the feeder (e.g., feeder extremities)

iv. Operating status of all equipment that is monitored and controlled by CVR. This includes feeder circuit breaker and recloser status, open/closed position of all capacitor bank switches, and capacitor bank protective devices (e.g., neutral shift detection)

v. Voltage regulator tap position (if available)

c. Data "scrubbing" should be performed to identify and eliminate all data anomalies (e.g., unreasonable values, "stale" information that has not changed for an extended period) in the supplied data. Failure to detect and eliminate these data problems can result in incorrect results.

b) ESTA's understanding of the Consumers Energy approach

a. Consumers provided data from all 50 feeders on which CVR was implemented. On twenty of these feeders, demand response CVR was also conducted on selected peak load days in 2020.

b. List of variables: CVR Status, Timestamp, Phase –X kW Load, Phase –Y kW Load, Phase –Z kW Load, Phase-X secondary load voltage, Phase-Y secondary load voltage, Phase-Z secondary load voltage, Temperature, Total kW Load, Average Sub Voltage

c. Duration: varies for each feeder. "010007" feeder was the first feeder to go under voltage reduction program on August 7, 2019 and "065502" feeder was the last feeder, CVR starting on December 8, 2020. The CVR program continued until April 2021.

d. Resolution: SCADA (Supervisory Control and Data Acquisition) data provided to ESTA was recorded at a 15 min interval.

e. Data Scrubbing: A significant amount of data was scrubbed for several reasons including telemetry issues, Application issues, holidays, and data errors. Scrubbed data was excluded from this analysis.

c) Comparison of Consumers Energy approach to best industry practices

The list of measurement and equipment status information in the Consumers Energy system is consistent with devices that are installed on most electric distribution circuits operated by electric distribution utilities. However, most solutions at other utilities provide a means of obtaining near-real-time voltage feedback from AMI meters or bellwether line voltmeters. Consumers Energy does not receive such voltage feedback on a continuous basis. However, day-after voltage measurements from AMI are reviewed daily by Consumers Energy to detect any voltage problems which are subsequently corrected.

d) **Findings, conclusions, and overall assessment of Consumers Energy approach**

a. The data measurements supplied to the Consumers Energy CVR system provide the minimum amount of information that is needed for operation of the CVR system and for performing M&V of the CVR results.

b. Some data "scrubbing" was needed to eliminate data anomalies, such as "stale" data that remains constant for an extended period. However, enough data remained for performing the M&V after removing suspect data.

c. ESTA notes that the need for data scrubbing during M&V analysis is common in the industry and that the amount of data scrubbing was far less for Consumers Energy's data than the data scrubbing required for M&V purposes at other electric utilities.

d. While Consumers Energy does not currently have any "edge of network" devices, it should be possible to add these devices in the future to either a rules-based solution or ADMS model-driven solution, if needs arise (e.g., widespread electric vehicle charger deployment, addition of significant penetration of rooftop solar PV generators).

5.5 METHOD OF COMPUTING CVR FACTOR

The methods used to compute CVR factor for waste energy reduction and peak demand reduction are slightly different. Therefore, separate sections are provided below for the two operating modes.

5.5.1 CVR FACTOR FOR WASTE ENERGY REDUCTION

a) General Requirements

- M&V analysis must determine the CVR factor for individual distribution feeders with an accuracy of +/- 5% or better. CVR factor is the percentage change in power or energy attributable to voltage reduction divided by the percentage reduction in voltage.

- Separate CVR factors must be provided for Energy Waste reduction and Peak Demand reduction

- Measurement and Verification (M&V) Analysis must separate the electrical impact of voltage reduction on power or energy consumption from other factors that impact power or energy consumption. Other factors include:
  i. Ambient weather conditions and season
  ii. Day of week, time of day

- CVR voltage and load reductions were calculated by averaging all of the day "CVR On"/"CVR Off" readings and comparing the difference.

- $$CVR\ factor = \frac{(Avg.\text{ CVR Off } Load - Avg.CVR\ On\ Load)\ /\ Avg.\text{ CVR Off } Load}{(Avg.\text{ CVR Off } Voltage - Avg.CVR\ On\ Voltage)\ /\ Avg.\text{ CVR Off } Voltage}$$

b) ESTA's understanding of the Consumers Energy approach

- Consumers Energy uses a "Matching Pairs" concept for its CVR M&V analysis. The process involved comparing load measurements for a set of days on which CVR was "on" (voltage reduced) with a set of load measurements for an equal number of days when CVR was "off" (normal voltage applied).

- CVR-On data sets were compared with CVR-Off data sets having "similar" characteristics. "Similar" days are either weekdays or weekends having similar average daily temperatures:

    - **Weekdays versus Weekends:** Data sets containing weekday loads were compared with other weekdays. Weekend days were compared with other weekend days.

    - **Temperature Range:** Each data set contained load data for each "season" which includes days on which the average temperature was within a specified range. Consumers Energy determined the range of seasons based on predetermined temperature thresholds. For example, when mean temperature of the day goes beyond 65 F consistent for consecutive days, "Summer" season is considered to have begun, and it continues till threshold for "Fall" season is reached. Based on this following season ranges were identified: Start Day, End Day
        i. 2019 Summer: 8/7 to 10/1
        ii. 2019 Fall: 10/2 to 11/5
        iii. 2019/2020 Winter: 11/6 to 3/24
        iv. 2020 Spring: 3/25 to 5/22
        v. 2020 Summer: 5/23 to 9/6
        vi. 2020 Fall: 9/7 to 11/20
        vii. 2020/2021 Winter: 11/21 to 3/9

.

- Each CVR On day has a corresponding CVR Off day with the same day type (weekday or weekend) and season. An equal number of CVR On days and CVR Off days is needed for this analysis. If the number of days in each category is not the same, the M&V algorithm will exclude days from the category with higher number of days by first taking the mean load and temperature of each day and whole day and season category and eliminate the day with mean farthest from category mean.

- Once the CVR on-off cycle is completed, the load and voltage value are collected for each feeder over a resolution of 15 mins. The CVR factor is calculated by averaging all days with "CVR On"/"CVR Off" readings and comparing the difference, as shown below:

$$CVR\ factor = \frac{(Avg.\text{ CVR Off } Load - Avg.\ CVR\ On\ Load) \Big/ Avg.\text{ CVR Off } Load}{(Avg.\text{ CVR Off } Voltage - Avg.\ CVR\ On\ Voltage) \Big/ Avg.\text{ CVR Off } Voltage}$$

- Using this calculation, Consumers Energy found that from date 8/7/2019 to 12/31/2020, for all the CVR experiments conducted on all 50 feeders, the average CVR factor they were able achieve

was 0.82, with it ranging from 1.34 to 0.07. The average voltage drop was 2.31%, while the average load drop was 1.9%.

- The Consumers Energy M&V approach assumes that the primary factors other than voltage that affect the average load on a given feeder are day of week (i.e., weekday versus weekend, holidays excluded), average ambient temperature, and season.

- Based on this assumption, the loading on a selected feeder will be the same on all weekdays in each season that have the same daily average temperature if the voltage is the same. For example, the loading on a selected feeder for two summer weekdays (Monday through Friday) that have the same average temperature will be approximately the same if normal voltage is supplied to the feeder.

- As a result of the assumptions listed above, any loading difference on two summer days with the same average temperature can be attributed to differences in applied voltage.

- To compute the CVR factor for a given feeder, Consumers Energy performed the following tasks:

    - Defined seasons as a consecutive set of days where daily average temperature is within a given range, and created separate files containing load and voltage data for each season.

    - Separated the above seasonal data files into two files: one containing only weekdays (Monday through Friday) and one containing only Weekends (Saturday and Sunday). Loading for special days and holidays was excluded from the analysis.

    - Separated the weekday file and the weekend file into two files: one file contains only loading data when voltage was reduced (CVR on) and one file containing loading data when voltage was not reduced.

    - The next step in the process was to ensure that number of “CVR On” days in each season’s weekday file is the same as the number of “CVR Off” days in each season’s weekday file.

    - Consumers Energy then computed the average daily load and the average voltage using data in the “CVR On” file and the average daily load and voltage using data from the “CVR Off” file. Then Consumers Energy computed the percentage difference in average daily load and average voltage between the On days and Off days

    - The CVR factor for the feeder in the given season is the percentage difference in feeder loading for CVR On and CVR Off days divided by the percentage difference in average voltage for CVR On days and CVR off days.

- CVR factors were computed as described above for each of the fifty feeders in the CVR demonstration. The results are shown in . As seen in T 5-6, CVR factor varied from feeder to feeder ranging from 0.07 to 1.34, with the average CVR factor for this group of feeders being 0.82.

- In 2021, Consumers Energy plans to use a new Predictive software tool called MetrixND to forecast what the load "would have been" had voltage not been reduced (i.e., normal voltage applied). Consumers Energy plans to use this load forecasting tool to derive a CVR factor for each tested circuit.

Table 5-6 CVR Factors for Each Feeder using "Matching Pairs" Method

c) Comparison of Consumers Energy approach to best industry practices

- Regression Analysis of Day-On/Day-Off data
  - The CVR M&V approach that is most widely used in the electric utility industry involves multiple regression analysis to determine the relationship between various independent variables that typically impact load (ambient temperature, day of week, voltage level, etc.) and load.
  - The analysis is applied to data collected during CVR Day-On/Day-Off or CVR week on/week off demonstrations like the CVR pilot demonstrations conducted by Consumers Energy.
  - The resulting regression formula is used to estimate what the feeder load "would have been" on a "CVR On" day (reduced voltage) if the voltage had not been reduced.
  - The CVR factor can then be determined by comparing the actual measured loads for CVR On days against the estimated load computed using the regression formula.
- ESTA performed a regression analysis as described above using the day-on/day-off data supplied by Consumers Energy. The results of this analysis are summarized in Table 5-7 below. The CVR

factors computed using regression analysis and the Consumers Energy "matching pairs" approach was somewhat different for individual feeders. The CVR factors computed for individual feeders using regression analysis ranged from 0.2 to 1.41 (compared with the range of .07 to 1.34 for matching pairs). However, the overall average CVR factor for the entire set of CVR feeders computed using the two approaches was similar: 0.77 to regression analysis and 0.82 for matching pairs. Note that the regression analysis performed by ESTA has a modelling error of +/- 3.7%. So the range of the regression analysis is 0.74 to 0.79.

- ESTA finds that the results obtained using the two independent and significantly different approaches are comparable and consistent with results published by other electric utilities. As a result, ESTA concludes that the approach used by Consumers Energy for computing the CVR factors for Waste Energy Reduction is valid and accurate.

Table 5-7 Comparison of Feeder CVR Factors Using Matching Pairs and Regression Analysis

Feeder ID	Substation	Circuit	CVR Enabled Date	Consumers CVRf	Model Error Rate	Model CVRf	Difference
1903	Roberts Street	Bender	6/10/2020	0.99	5.49%	1.13	14%

- Neural Net Methodology

  - ESTA has used neural net methodology to compute CVR factors with an accuracy of 2% or better, However, this method requires several years of data to "train" a model that is used to predict what the load would have been on a future date if voltage had not been reduced. Note that this approach may not be possible at this time for Consumers Energy because the CVR pilot projects have been conducted during the pandemic, which has exhibited considerably different loading patterns due to work-at-home restrictions.

d) Findings, conclusions, and overall assessment of Consumers Energy approach

a. ESTA has reviewed the Consumers Energy "Matching Pairs" M&V method and offers the following comments and conclusions.

b. A major assumption on which the "Matching Pairs" analysis is based is that differences in average feeder loading observed in the day-on and day-off data sets are primarily due to voltage differences rather than differences in ambient temperature. For this assumption to be valid, the load must remain nearly constant with normal voltage applied for the days in each season.

c. ESTA examined the relationship between load and ambient temperature and observed the expected relation between load and temperature for Consumers Energy CVR feeders. Figure 5-3 contains graph showing the relationship between load and ambient temperature for one of the Consumers Energy feeders in the Selected CVR feeders. As expected, the relationship is a bathtub shaped curve with sloping lines that are different for each feeder. ESTA used the bathtub curve sloping lines for each feeder to determine the approximate change of load given the range of ambient temperatures observed.

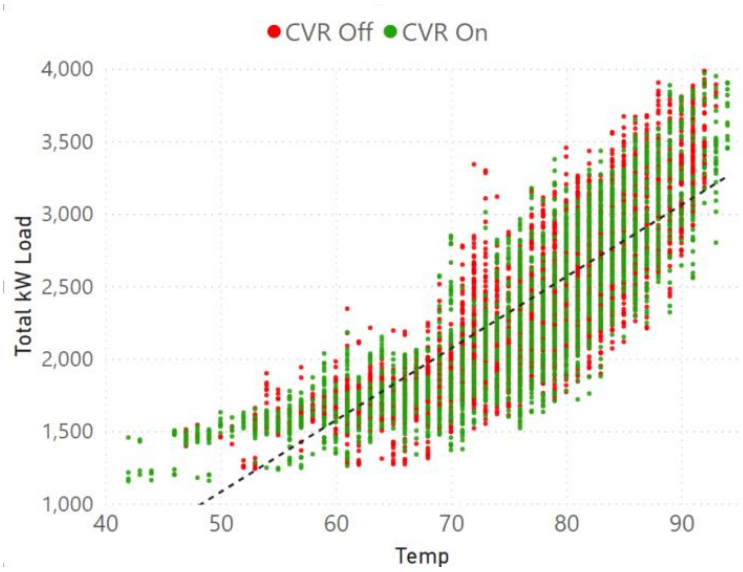

Figure 5-3 Variation of Load with Temperature on a CVR feeder

d. The results showed that for most feeders, the feeder load changed by only a small percentage amount for the range of temperatures included in the "seasonal" data sets. Table 5-8 shows the approximate change in load that can be attributed to the temperature differences in the matching pairs data sets for weekdays in summer. Hence, ESTA concludes that average load variations in the Day-On and Day-Off datasets are primarily due to voltage reduction. This is shown in the table below for summer weekdays:

Table 5-8 Expected Change in Weekday Load for Temperature Variation in Summer

Feeder ID	Day Type	CVR Temp On	CVR Temp Off	Load Change per F	Load variation due to Temp
1903	Weekday	72.75	72.95	1.20%	-0.25%
1903	Weekend	69.93	72.28	1.21%	-2.83%

e. Since the matching pair data set loading differences are primarily due to voltage reduction, ESTA believes it is acceptable and valid to use Consumers Energy's averaging technique to determine CVR factors.

f. The overall average CVR factor for the CVR feeders computed using Consumers Energy Matching Pair approach compares favorably with the overall average computed using regression analysis. ESTA believes this further confirms the approach. Significant differences in the results for individual feeders is attributable to the small number of data samples.

5.5.2 CVR FACTOR FOR PEAK DEMAND REDUCTION

This section describes the approach used for computing the Peak Demand reduction benefits. This approach is slightly different than the previously described procedure for computing the Energy Waste Reduction benefits.

a) General Requirements

a. Measurement and Verification (M&V) analysis must determine the CVR factor for individual distribution feeders with an accuracy of +/- 5% or better. CVR factor is the percentage change in power or energy attributable to voltage reduction divided by the percentage change in voltage.

b. Separate CVR factors must be provided for Energy Waste reduction and peak demand reduction.

c. Measurement and Verification (M&V) Analysis must separate the electrical impact of voltage reduction on power or energy consumption from other factors that impact power or energy consumption. Other factors include:
   i. Ambient weather conditions and season
   ii. Day of week, time of day

d. CVR voltage and load reductions were calculated by averaging all of the day "CVR On"/"CVR Off" readings and comparing the difference.

e. $$CVR\ factor = \frac{(Avg.\ \text{CVR Off}\ Load - Avg.CVR\ On\ Load)\ /\ Avg.\ \text{CVR Off}\ Load}{(Avg.\ \text{CVR Off}\ Voltage - Avg.CVR\ On\ Voltage)\ /\ Avg.\ \text{CVR Off}\ Voltage}$$

b) ESTA's understanding of the Consumers Energy approach

- The method used by Consumers Energy for computing the CVR factor for peak demand reduction is very similar to the method described above. Consumers Energy assumed the CVR factor obtained above would be the same for peak demand reduction as waste energy reduction. Then the peak demand reduction was calculated as follows:

$$Peak\ Demand\ Reduction = CVR\ Factor\ for\ waste\ energy\ reduction \times Voltage\ Reduction$$

- In 2021, Consumers Energy plans to use "MetrixND", a predictive software tool from ITRON to determine the CVR factor for Peak Shaving reduction. The analysis performed by this software tool is like the regression analysis ESTA used for determining a CVR factor for peak shaving reduction (see next Section). This software determines what the peak load "would have been" during a Peak Demand reduction event if normal voltage had been applied instead of reduced voltage. Consumers Energy plans to use measurements of the following independent variables to perform this analysis:
  - Solar irradiation and hours of sunlight on a given day.
  - Loading on recent past days
  - Dry Bulb temperature

c) Comparison of Consumers Energy approach to best industry practices

- Regression Analysis of Day-On/Day-Off data
  - The CVR M&V approach that is most widely used in the electric utility industry involves multiple regression analysis to determine the relationship between various independent variables that typically impact load (ambient temperature, day of week, voltage level, etc.) and load.
  - The analysis is applied to data collected during CVR Day-On/Day-Off demonstrations like the CVR pilot demonstrations conducted by Consumers Energy.
  - The resulting regression formula is used to estimate what the feeder load "would have been" on a "CVR On" day (reduced voltage) if the voltage had <u>not</u> been reduced.
  - The CVR factor can then be determined by comparing the actual measured loads for CVR On days against the estimated load computed using the regression formula.

- ESTA performed a regression analysis as described above using the day-on/day-off load data and average ambient temperature data supplied by Consumers Energy. The objective of this analysis is to determine what "would have happened" if voltage had not been reduced on the DR day in question.

- This model is trained using data when CVR status is "CVR off". This model uses inputs like voltage, temperature, heating and cooling days and temporal features like hour of the day and season. This model can account for temperature and customer behavior variations and is found to have an average error rate of 3.76%. This trained model is then used on "CVR On" hours of each feeder and demand response day to predict what the load would have been for the hours when CVR was on, if mean voltage instead of reduced voltage was applied. This predicted load is then compared with actual load to compute a mean CVR factor.

- Consumers followed a pre-determined peak reduction schedule as mentioned below:

Table 5-9 Peak Reduction Schedule

DR Date	DR Time Range	Feeder IDs
7/1/2020	1400 - 1500	050403,

- Regression model is used for each of the feeder on each CVR Date along the time range mentioned in above table to predict load without CVR. Using this a CVR factor is calculated for each instance as follows:

$$CVR\ Factor = \frac{(Avg.\text{ Predicted } Load - Avg.\ CVR\ On\ Load)\Big/ Avg.\text{ Predicted } Load}{(Avg.\text{ CVR Off } Voltage - Avg.\ CVR\ On\ Voltage)\Big/ Avg.\text{ CVR Off } Voltage}$$

Based on this formula an average CVR factor of 1.51 is computed for all feeders on all Demand response days. As mentioned above average error rate of regression model was 3.86% so ESTA can claim that CVR factor should lie with $\pm$3.86% of 1.51 or between 1.45 and 1.56.

- The results of this analysis were compared with Peak Demand Reduction CVR factor computed by ESTA for another electric utility (utility name confidential). As seen in Figure 5-4, the Peak demand was reduced 600kW (6.5%) during a 4-hour, 15-minute voltage reduction of 4.5%. The Peak Demand CVR factor for this utility was 1.45 (6.5% / 4.5%). This is consistent with the results obtained by ESTA for Consumers Energy.

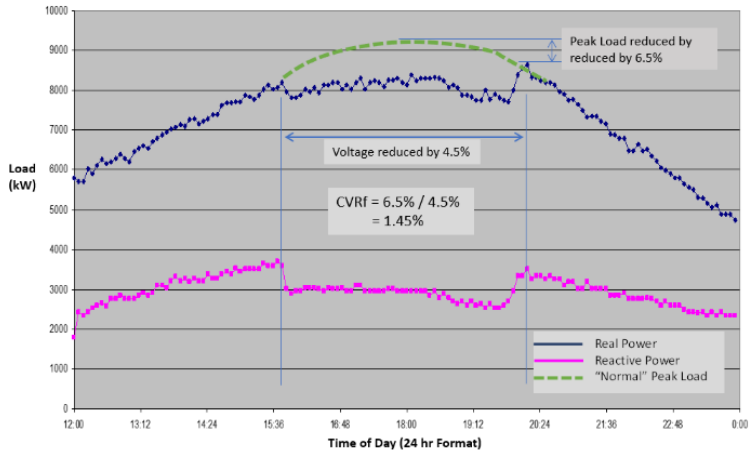

Figure 5-4 Results of Peak Demand CVR

d) Findings, conclusions, and overall assessment of Consumers Energy approach

a. ESTA has reviewed the Consumers Energy "Peak Demand Reduction" M&V method and offers the following comments and conclusions.

b. An average CVR factor of 1.51 is computed for all feeders on all Demand response days. As mentioned above average error rate of regression model was +/- 3.89% so that the CVR factor should lie with of 1.51 or between 1.45 and 1.57

c. Table 5-10 below shows the average Peak demand CVR factor that ESTA computed for each Consumers Energy feeder on all demand response days.

Table 5-10 Peak Demand CVR factors for Individual feeders

Feeder ID	Model Error Rate	CVR Factor
7303	4.10%	1
34401	4.26%	3.73
41303	2.95%	0.65
43502	3.29%	0.69
50403	3.82%	1.61
56802	2.12%	1.32
72702	3.45%	1.91
81502	5.94%	0.33
90701	4.39%	1.11
110802	3.59%	1.71

Average	**3.89%**	**1.51**

d. Figure 5-5 below shows the average effect of peak demand reduction for all feeders.

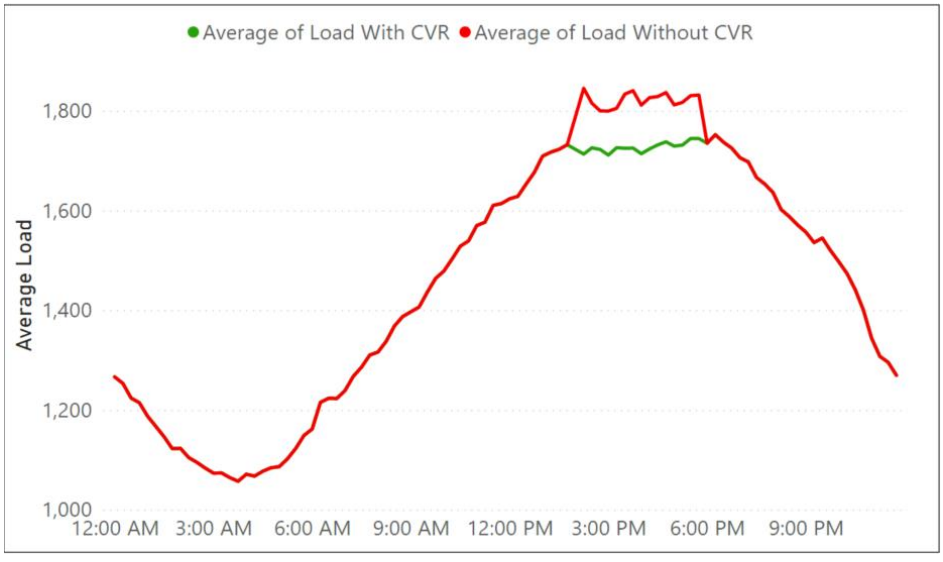

Figure 5-5 Average Peak Demand CVR Factor For Consumers Energy

6 SUMMARY OF FINDINGS CONCLUSIONS AND RECOMMENDATIONS

Following is a summary of ESTA's major findings, conclusions, and recommendations resulting from this assessment:

- **Feeder Selection:** As stated earlier in this report, the approach used by Consumers Energy to select feeders for its CVR Demonstration project far exceeds the feeder selection approach used by many other utility companies (based on ESTA experience).
    - Key characteristics of the CVR demonstration feeders selected by Consumers Energy match the characteristics of the broader set of "CVR Proposed" feeders on which CVR may be implemented in the future. While some characteristics are not the same, customer mix is very similar between the two groups. ESTA considers this to be one of the most important factors that determines the CVR factor for a given feeder.
    - As a result, ESTA believes that the selected CVR feeders represent the broader community of Consumers Energy feeders on which CVR is likely to be implemented.
    - In ESTA's opinion, it is acceptable to assume that the results obtained for the initial 50 feeders can be applied to future CVR feeders selected from the CVR Proposed feeder set.
- **CVR Solution:** The Consumers Energy CVR solution is a DSCADA rules-based solution, meaning a set of predetermined rules involving the application of Boolean logic to measurements acquired by the distribution SCADA system.
    - Most of the CVR solutions that have been successfully implemented by North American electric distribution systems are rules-based systems like what has been implemented by Consumers Energy. While this approach has some limitations, such as inability to adapt automatically to feeder reconfiguration, the approach has the benefit of simplicity, ease of operating and maintenance, and cost effectiveness, while providing the expected benefits.
    - Shortcomings of the existing approach include:
        - Lack of immediate voltage feedback to alert system operators to low or high voltage conditions on the feeder. Currently, such events may be detected the next day through manual review of voltage records from AMI. This approach is generally acceptable if major voltage deviations (e.g., voltage dips well below lower ANSI C84.1 limit) do not routinely occur.
        - Inability to adapt automatically to changing feeder configuration. Currently, Consumers Energy disables CVR if the feeder is reconfigured. While not the preferred approach, disabling CVR is acceptable if this is for a short duration (i.e., normal feeder configuration restored as quickly as possible),

- In the future, Consumers Energy should consider implementing model-driven VVO on its new ADMS. This should eliminate the shortcomings listed above.

- **Controlled Devices**

  - Consumers Energy controls switched capacitor banks and voltage regulators on its feeders. Within the industry, this is the most common complement of controlled equipment.

  - In the future, additional control requirements may apply. Examples include smart inverters and distributed generators. If these new requirements emerge at Consumers Energy, and ADMS-based, model-driven solution may be required due to the impracticality of handling these requirements with fixed Boolean logic.

- **Measurement data**

  - The measurements and equipment status information acquired by Consumers Energy for CVR purposes is adequate for meeting the basic needs of this application.

  - Some "scrubbing" was needed to eliminate questionable data (such as "stale" data measurements) collected during the CVR demonstration project. However, it is noted that data scrubbing is typically required on all M&V projects of this type, and that the amount of data scrubbing for Consumers Energy was far less than other M&V projects done by ESTA.

  - Adding near-real-time voltage measurements or low/high voltage alarms from AMI or bellwether meters would be beneficial, especially for heavily loaded feeders that are routinely operated close to the industry limits. Adding voltage feedback will enable Consumers Energy to gain additional benefits by operating with small margins (closer to voltage limits).

- **Approach to Measurement and Verification and Results Obtained**

  - The Matching Pairs M&V approach is relatively easy to understand and implement, compared to other advanced techniques (such as regression analysis and neural network modelling). As a result, it is possible to cross check the results using simple averaging to confirm the results. Another advantage is the ability to gain acceptance of the results by decision makers who do not have an advanced mathematical and statistical background.

  - ESTA performed an M&V analysis on the Consumers Energy data using multiple regression analysis that included consideration of loading, voltage, and ambient temperature. Regression analysis is the most widely used approach in the electric utility industry for CVR M&V.

  - The overall average CVR factor for the CVR feeders computed using Consumers Energy Matching Pair approach is 0.82, which compares favorably with the overall average computed using

regression analysis (0.77 +/- 3.7%). We believe this further confirms the approach. Significant differences in the results for individual feeders is attributable to the small number of data samples.

- ESTA concludes that the results obtained by Consumers Energy during its CVR demonstration and analysis are valid and representative of results than can be received by implementing CVR on the CVR Proposed data set.

- ESTA computed a CVR factor for Peak Demand reduction using regression analysis to determine what "would have happened" during peak load conditions if normal voltage were applied on Demand Response days when CVR Peak Demand reduction occurred. The result of this analysis was a Peak Demand Reduction CVR factor of 1.56 +/- 3.86% on average for the 20 feeders on which Peak Reduction CVR was applied.

- Consumers Energy has assumed that the CVR factor for Peak Demand reduction is the same (0.82) as the CVR Factor for Waste Energy Reduction, which is a very conservative assumption compared to the results computed by ESTA. Based on the results of ESTA's Peak demand CVR analysis and the results at one other electric utility (undisclosed), the results are considerably higher than the CVR factor for peak demand reduction assumed by Consumers Energy. The main reason for this difference is that the complement of equipment and appliances running during daily peak load hours is considerably different than the equipment complement running on average. For example, the amount of air conditioning load during peak load hours on a hot summer day is likely to be significantly higher than the average AC load for the day.

In 2021, Consumers Energy plans to use "MetrixND", a predictive software tool from ITRON to determine the CVR factor for Peak Shaving reduction. The analysis performed by this software tool is like the regression analysis ESTA used for determining a CVR factor for peak shaving reduction. In ESTA's opinion, this approach will yield much more accurate results for the Peak Demand CVR factor than the current conservative approach. ESTA strongly recommends that Consumers Energy use this approach for future analysis of peak demand CVR reduction.

Appendix A CVR BACKGROUND INFORMATION

A.1 VOLTAGE REDUCTION

As electric utilities seek to address energy efficiency and conservation portfolios, many electric distribution utilities are turning to voltage reduction to satisfy energy efficiency, demand reduction, and energy conservation objectives. Voltage reduction involves operating the distribution feeder at a voltage that is in the lower portion of the acceptable voltage range (See Figure 6-1). Electric utility experience, backed by extensive laboratory testing, has shown that many electrical loads, especially electric motors, consume less real and reactive power and perform just as well (or better) when voltage is lowered slightly. When voltage reduction is performed whenever possible (up to 24 hours per day, seven days per week), this is called "Conservation Voltage Reduction". This is because 24-hour-per-day operation is primarily intended to promote energy conservation. If voltage reduction is used only during peak load periods for purposes of peak shaving, the term voltage reduction (VR) or voltage optimization is commonly used.

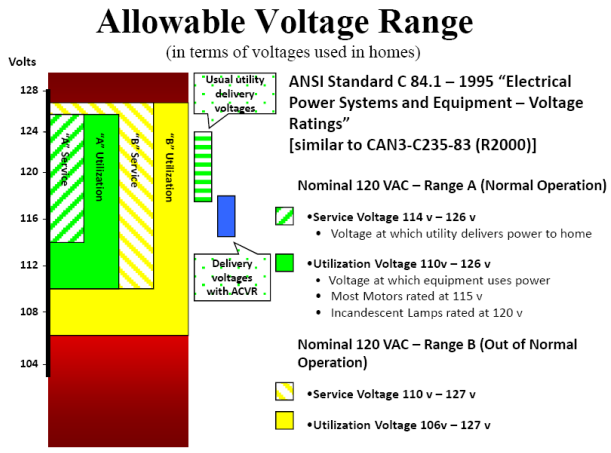

Figure 6-1 Allowable Voltage Range (per ANSI C84.1)

Many electric utilities and their associated grid management authority have used voltage reduction as a means of reducing power quickly during a peak load emergency. In the past, such voltage reductions were referred to as "brown-outs" due to the dimming effect voltage reduction may have on incandescent light bulbs. For the most part the term no longer applies as the newer generation of compact fluorescent lamps remains bright as voltage is reduced by up to five percent. Numerous utilities are planning to operate with reduced voltage on a continuous basis (for energy conservation) or during peak load periods (for demand reduction).

To implement CVR effectively with no adverse impact on consumer electrical loads, it is often necessary to implement distribution infrastructure improvements to "flatten" the voltage profile along the feeder. This allows more voltage reduction without violating minimum voltage constraints. Figure 6-2 illustrates the use of switched capacitor banks to "flatten" the voltage profile, followed by voltage reduction. The green line in this Figure 6-2 represents the starting voltage profile at one point in time along the feeder. The red line shows the impact of voltage "flattening". In this cases the effect was achieved by switching on the three switched capacitor banks that are installed on the feeder. The brown line in Figure 6-2, shows the effect of voltage reduction on the "flattened" voltage profile. As seen in Figure 6-2, the voltage level at the end of the feeder that is furthest from the substation changes very little from the starting point. However, the voltage at all other points along the feeder are reduced considerably. This illustrates the benefit of voltage conditioning.

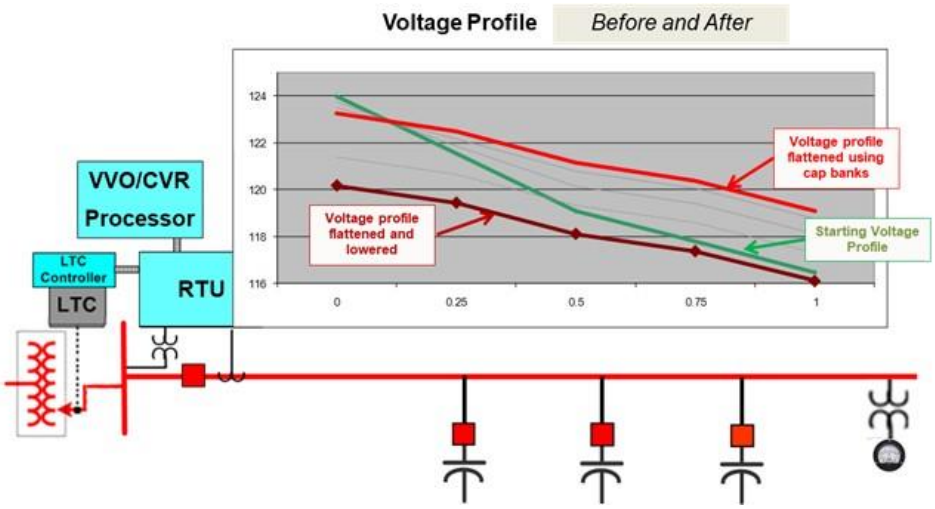

Figure 6-2- "Flattening" And "Lowering" The Voltage Profile

Many electric utilities view VR as a very attractive measure for efficiency improvement, because, in most cases, significant benefits can be achieved for a minimal investment and with no customer sacrifices. Because VR can usually be implemented without making major investments in equipment and infrastructure improvements, benefits can be achieved in the shortest possible time.

The specific benefits that can be achieved vary based on customer type (residential, commercial, industrial, etc.), time of day, day of week and season, climate zone, and other such factors. The amount of benefit is also affected by the degree to which voltage can be reduced. Feeders whose minimum voltage is near the bottom of the acceptable range will provide little or no CVR benefits, while feeders with higher distribution voltage often gain the most from CVR.

CVR benefits will be affected by new "up and coming" appliances that comprise a growing percentage of the load. Many new appliances will be equipped with electronic controls that improve the nominal efficiency of the device. Many of these controls exhibit "constant power" behavior which is not favorable for achieving CVR benefits. With constant power loads, the electricity consumed by the device stays constant as voltage is reduced. However, as the voltage is reduced, current increases which can produce higher electrical (I^2R) losses on the feeder. Due to the critical nature of the application (e.g., system emergency voltage reduction), it is important to be able to predict the outcome of voltage reduction.

A.2 SCADA "RULES-BASED" APPROACH

Consumers Energy uses one of the most common approaches to CVR: the SCADA "rules based" approach. This approach is depicted in Figure 6-3. This approach determines what volt-VAR control actions to take by applying a predetermined set of logical "rules" to a set of real time measurements from the associated substation and feeder. An example rule is: "If the voltage measured at point "X" is less than 120 volts AND the reactive power flow measured at the substation end of the feeder is greater that 900kVAR (lagging), then switch capacitor bank "1" to the ON position". These rules are determined in advance by the distribution engineers and operators using power flow analysis or general knowledge about the historical operation of the feeder.

The SCADA rules-based approach relies on intelligent controllers for interfacing with the switched capacitor banks and voltage regulators. The SCADA rules-based approach uses the Consumers Energy Distribution Supervisory

Control and Data Acquisition (DSCADA) system to interface with the field devices and intelligent controllers. The communication facilities enable the system to base its control actions on overall feeder conditions rather than just on local conditions at the site of the capacitor bank or voltage regulator. The communication facilities also enable Consumers Energy to monitor the operating status of the voltage regulators and switched capacitor banks so that appropriate actions can be taken immediately when a component failure occurs.

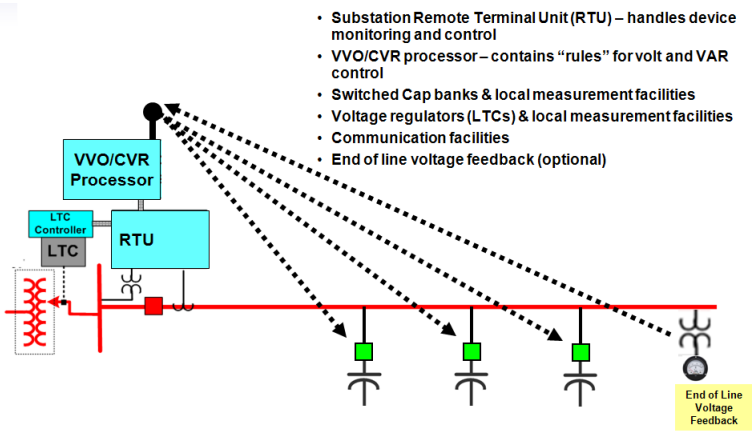

Figure 6-3 SCADA Rules Based Approach

This approach works well for the operating environment that exists on many electric utility distribution feeders today (e.g. minimal DG, infrequent changes in feeder configuration). However, in the future as the penetration of large DG units grows and advanced distribution applications (such as Fault Location Isolation and Service Restoration (FLISR)) become prevalent, the rules-based approach may lack the flexibility to address all future operating possibilities. In such cases, a more sophisticated "model-driven solution" may be needed.

A.3 CVR FACTOR EXPLAINED

CVR factor reduction (also known as load-voltage sensitivity) is an industry standard metric for identifying the effectiveness of voltage on the electric distribution system. CVR factor is given by the following formula:

CVR factor = (% change in kWh energy consumption) / (% change in voltage)

As explained in following sections, the load-voltage sensitivity of a particular electrical device depends on the electrical characteristics of the individual device which can be determined through laboratory testing. The load-voltage sensitivity or CVR factor of an entire customer premise, an entire feeder, an entire substation, or other entity containing more than one appliance, depends on the aggregate load-voltage sensitivities of the individual appliances in the entity.

A.4 LOAD-VOLTAGE SENSITIVITY OF INDIVIDUAL DEVICES

Most electrical appliances consume less electric power when voltage is reduced. The relationship between voltage and electric power for an appliance is given by the "ZIP" model of the appliance, which is a combination of the following components:

- **Constant Impedance Component (Z)** – When voltage (V) applied to a constant impedance device is reduced, the current (I in amperes) drawn by the device decreases by the same amount to keep the impedance ratio (V / I) constant. So, when voltage is reduced, the consumed power (V x I) is lowered by a significant amount. Electric heating elements in water heaters and electric stoves are examples of loads that primarily have constant impedance behavior. Incandescent light bulbs, which are becoming a thing of the past, also exhibit constant impedance behavior. Figure 6-4 below contains a graph showing test results obtained when voltage applied to an incandescent light bulb was varied. The load-voltage sensitivity is the slope of this line, which is approximately 1.6, meaning that if voltage applied to the device is reduced by 1.0%, the power consumed would be 1.6%.

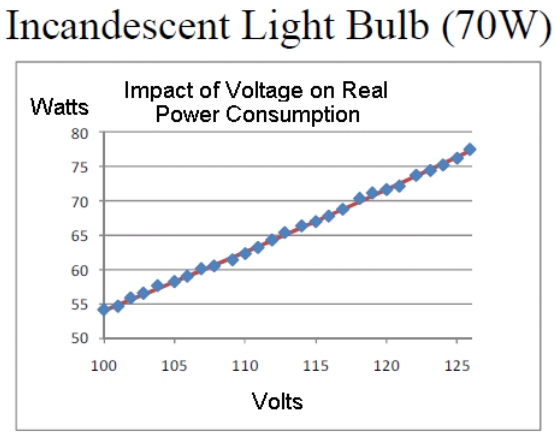

Figure 6-4 Load—Voltage Sensitivity Test Results for Light bulb

- **Constant Current Component (I)** – Constant current loads draw power in proportion to the applied voltage. That is, P= I x V, where current I is held constant. So, the power drawn by constant current loads will be lowered when voltage is reduced, but not as much as constant impedance devices. There are relatively few constant current devices that exhibit constant current behavior. Examples include welding units, smelting equipment, and electroplating processes. However, some electric vehicle chargers may exhibit constant current behavior. Normally, and EV charger exhibits a constant power behavior in which current increased as voltage is reduced to maintain a fixed power draw by the charger. However, when current reaches a maximum amount when current reaches a maximum allowable amount, the current drawn remains fixed and is clamped at the maximum as further voltage reduction occurs.

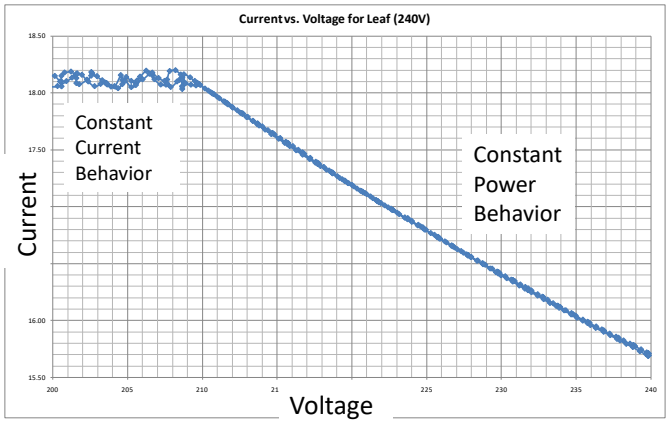

Figure 6-5 Load-Voltage Characteristic of EV Charger

- **Constant Power Component (P)** – Constant power loads draw the same amount of power regardless of the applied voltage. So, the CVR factor for constant power loads is zero. Computer power supplies are constant power devices as are many modern devices that used switched power supplies. Electric motors are often considered to be constant power devices. However, tests have shown that for small voltage reductions (a few percent), motors exhibit constant impedance behavior. Load-Voltage sensitivity for a computer power supply is shown in Figure 6-6 below.

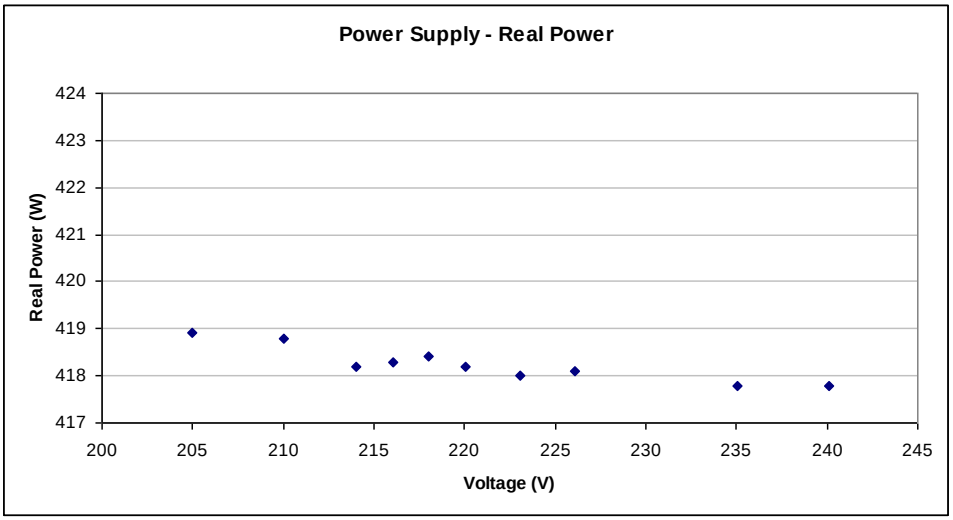

Figure 6-6 Constant Power Behavior of Computer power Supply

Commonly used electrical appliances usually exhibit individual CVR factors that are a combination of the ZIP component characteristics. Figure 6-7 below shows CVR factors for various types of electrical appliances.

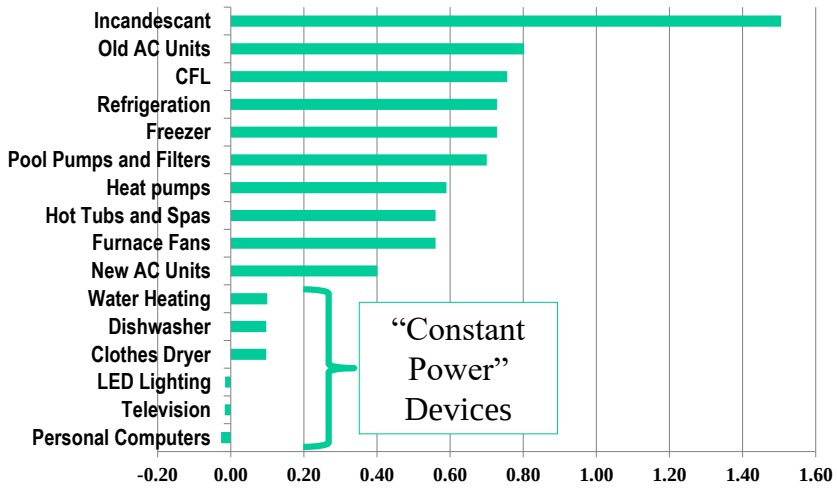

Figure 6-7 CVR Factors for Common AC Appliances

A.5 LOAD-VOLTAGE SENSITIVITY AT THE PREMISE AND FEEDER LEVEL

The power supplied to a single residential or commercial entity is the sum of the power consumed by all the individual electrical appliances within the entity. The Load-Voltage sensitivity or CVR factor for the single entity is the sum of the CVR factors for the individual types of appliances weighted by the percentage of load consumed by each appliance. Figure 6-8 and Figure 6-9 below show how the aggregate load-voltage sensitivity differs for a typical single-family residence and a commercial office building. For these examples, power consumed by each type of appliance has been obtained from RECS and CBECS data published by the US Department of Energy (DOE) for premises located in the "mixed-humid" climate zone. The energy consumed by individual appliances, and the premise CVR factor, would be different in other climate zones.

Figure 6-9 CVR Factor for a Typical Office building

Similarly, the CVR factor for an entire feeder or substation is the weighted sum of the CVR factors for the individual customers connected to the feeder or substation. In this case, the weighting factor is the percentage of total feeder power consumed by each entity.

It can be concluded that the load-voltage sensitivity depends only on the types of appliances and equipment served and the portion of energy consumed by each type of appliance. In other words, two entities (premises, feeders,

substations, etc.) that supply the same types of appliances and energy consumption per appliance will have the same CVR factor.

As explained above, aggregate load-voltage sensitivity depends on appliance type and climate zone. If all Consumers Energy substations and feeders are in the same mixed-humid climate zone, then CVR factor varies only by the customer mix (e.g., residential, commercial, industrial) served by the feeder or substation.

A.6 CVR "BENEFITS" FOR DIFFERENT TYPES OF FEEDERS

While the load-voltage sensitivity is nearly the same for a given set of appliances in a given climate zone, the energy conservation benefits (kWh reduction) for a given feeder or substation will depend on the following items:

- The amount of voltage reduction that is possible without violating voltage limits. A larger voltage reduction will result in larger kWh savings. The possible voltage reduction on short, lightly loaded feeders is usually greater than the possible voltage reduction on longer, heavily loaded feeders (which may be voltage-limited). For example, reducing the voltage by 2% on a 1.0 MWh load with a 0.7 CVR factor will reduced the consumed energy by 1.4%; if voltage can only be reduced by 1%, then kWh savings would be half that amount.

- The total energy consumption by the entity. A one percent voltage reduction on a heavily loaded entity will produce a greater kWh reduction than a lightly loaded entity. For example, reducing the voltage by 2% on a 1.0 MWh load with a 0.7 CVR factor will reduced the consumed energy by 1.4% of 1.0 MWh; a 2% voltage reduction on a 2.0 MWh load would save 1.4% of 2.0 MWh (twice the benefit).

LVD Planning
CONCEPT APPROVAL

Notification Concept Number: 1072892823

Project Title: Ferrand Estates
Work HQ: GRA
Date: 1/30/2025
Proposed Year of System Changes: 2026

Problem Description:

Ferrand Estates is a large, dense mobile home park in Grand Rapids serving approximately 429 customers. The underground electric system was installed decades ago and was not designed for the way the park has evolved over time. Homes and permanent structures have since been placed over portions of the underground system, leaving critical equipment and connections buried, difficult to access, and hard to repair safely.

Since 2021, the area has experienced 51 total outage events, including 41 unplanned outages. Unplanned outages in this location have an average restoration time (CAIDI) of approximately 269 minutes (4.5 hours), significantly driven by the difficulty in locating and repairing faults. While nearly half of unplanned events originate on secondary or service facilities, crews are often required to de-energize entire transformer areas to safely troubleshoot buried connections. As a result, the vast majority of unplanned Customer Minutes Interrupted (CMI) accrue at the transformer or primary level, impacting large groups of customers during restoration.

Operations reports being on site approximately once per month to address primary, secondary, or service-related issues in this park. Outages are frequently hard to locate, often occurring under newer trailer locations, with limited access and challenging MISS DIG constraints. The system also contains legacy Y-spliced secondary connections that are failure-prone and live-front transformer installations, which increase safety risk and further restrict restoration flexibility.

Portions of the vintage primary have already been replaced under fail-order conditions, restoring service in the moment but not correcting the underlying system design. Without comprehensive intervention, remaining vintage primary and buried secondary connections are expected to continue failing, resulting in long restoration times, repeated emergency work, and significant customer impact. Absent this investment, continued fail-order repairs are expected to restore service in the near term but will not improve restoration speed, access, or outage scope.

Alternative Solutions:

1. Remove the 9 existing 100 kVA live-front transformers and install 14 dead-front 100 kVA transformers as shown in the scope map. Install new 1/0 aluminum underground primary to connect the transformers. Replace all secondary in the area with 350 aluminum conductor, designed to current new-business voltage drop and flicker standards. Install secondary cabinets for every four services where feasible to improve system flexibility and maintainability. Replace one section of secondary prior to implementation under Notification 1072824896.

Install a new primary tie connecting the southeast corner of the loop to the neighboring loop to improve sectionalization during outages.
Estimated customer minutes saved =

Estimated Design Hours = 5036

Estimated Loaded Cost = $2,053,901

Miles = 6

2. Replace the 9 existing 100 kVA live-front transformers in the area with dead-front 100 kVA transformers as shown in the scope map. Replace all underground primary in the area with 1/0 aluminum conductor. Replace all secondary in the area with 350 aluminum conductor. Install secondary cabinets for every four services where feasible to improve system flexibility and maintainability. Replace one section of secondary prior to implementation under Notification 1072824896.
Estimated customer minutes saved =

Estimated Design Hours = 4602

Estimated Loaded Cost = $1,630,905

Miles = 6

3. Replace the 9 existing 100 kVA live-front transformers in the area with dead-front 100 kVA transformers as shown in the scope map. Replace all secondary in the area with 350 aluminum conductor. Install secondary cabinets for every four services where feasible to improve system flexibility and maintainability. Replace one section of secondary prior to implementation under Notification 1072824896.
Estimated customer minutes saved =

Estimated Design Hours = 4029

Estimated Loaded Cost = $1,343,473

Miles = 4.44

Recommended Alternative:

Alternative # 1 is recommended

This project is primarily focused on reducing outage duration (CAIDI) and the number of customers affected during each event, rather than outage frequency.

Alternative 1 is the only option that materially improves outage duration, customer impact, and operational safety by correcting the underlying causes of long restorations at Ferrand Estates.

Key Benefits

Reduced CAIDI: By eliminating buried secondary connections and adding accessible isolation points, crews can locate and repair faults faster and restore portions of the park while work continues.
Reduced Customer Minutes Interrupted: Improved sectionalization and an added loop tie significantly reduce the number of customers affected during outages, lowering total customer minutes interrupted.
Improved Reliability: Removal of vintage primary and failure-prone secondary infrastructure reduces repeat outages and ongoing emergency response.
Improved Safety: Replacement of live-front transformers with modern dead-front equipment reduces crew

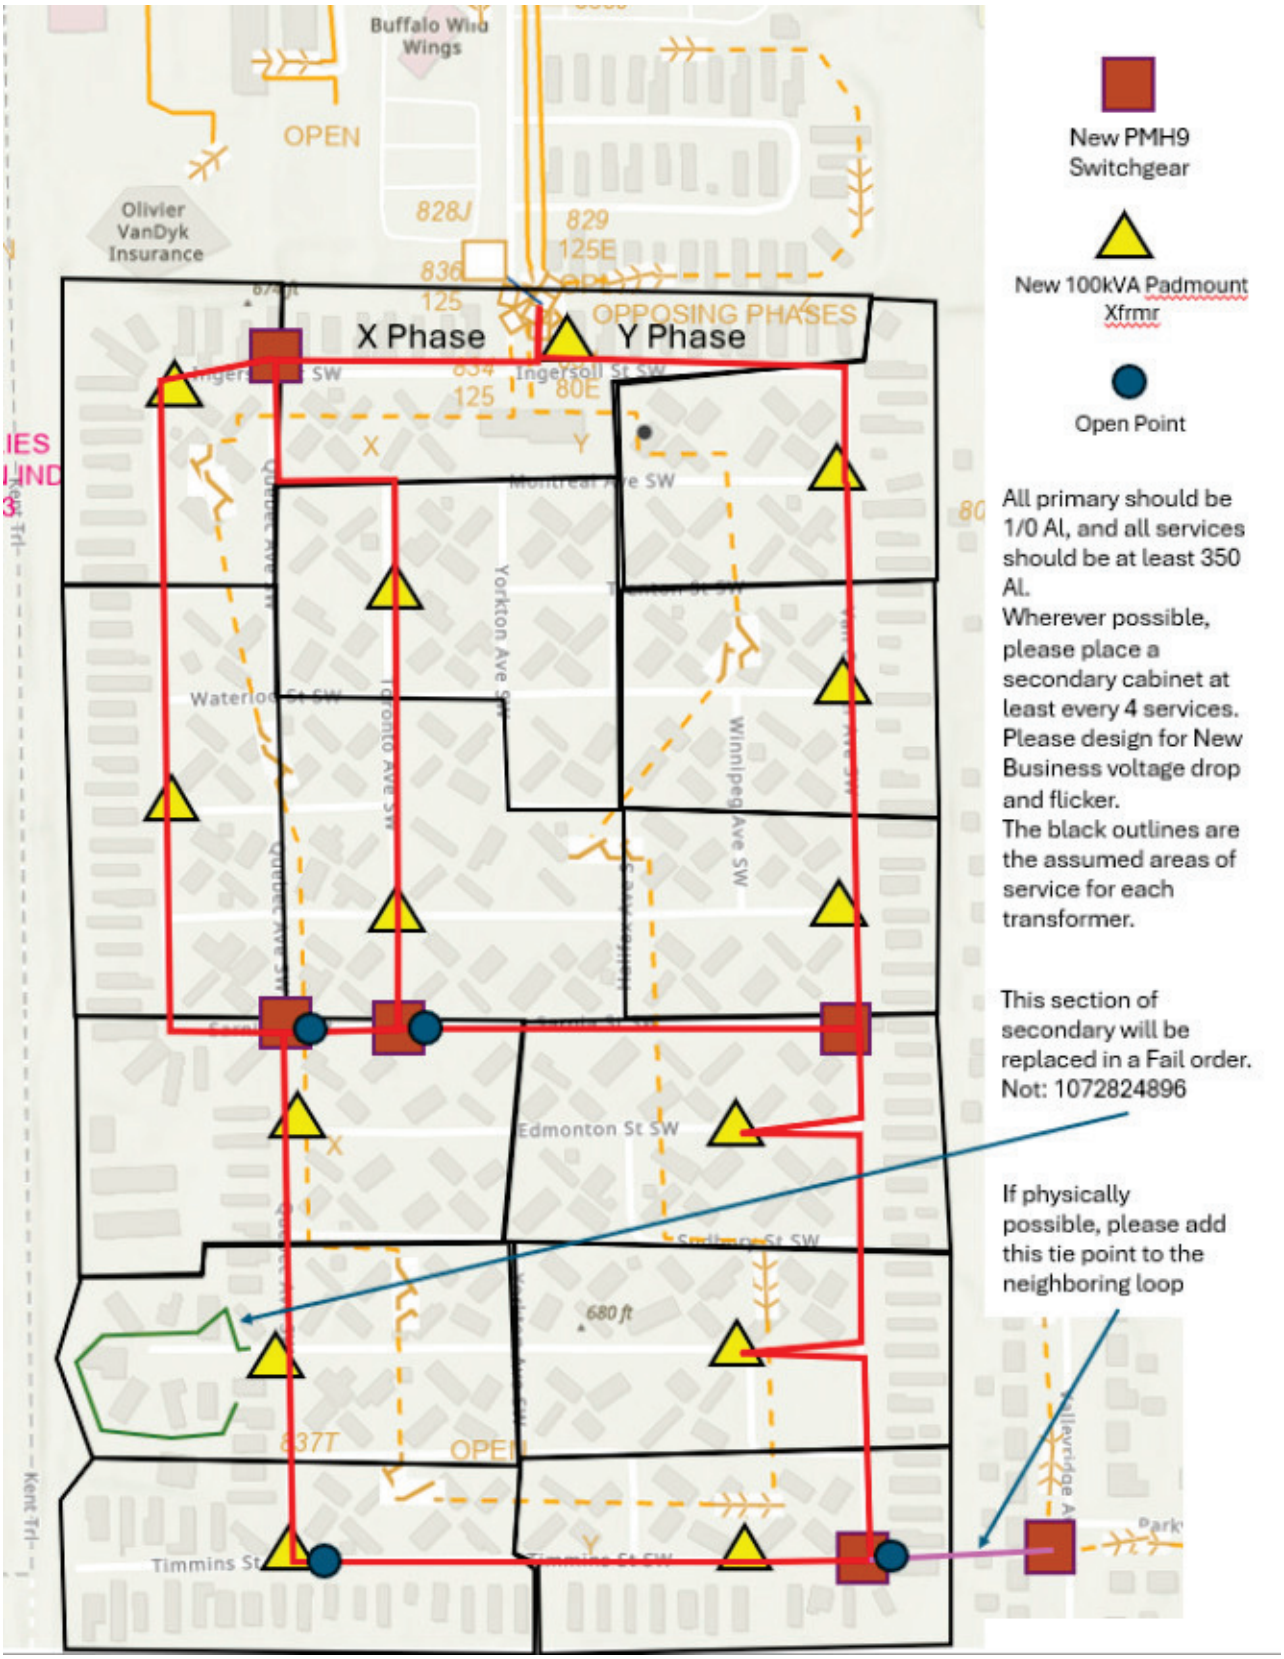
exposure and restoration risk.
Planned vs. Reactive Work: Converts ongoing fail-order and emergency repairs into a durable, maintainable system design.

Comparison to Other Alternatives

Alternative 3 (~$1.34M): Improves transformer safety and replaces secondary, but leaves vintage primary in service and does not improve sectionalization. Primary failure risk and long outage durations remain.
Alternative 2 (~$1.63M): Replaces primary, secondary, and transformers, but does not address system sectionalization or access limitations. Outage footprints and restoration challenges largely persist.
Alternative 1 (~$2.05M): Higher upfront cost, but the only alternative that delivers meaningful reductions in CAIDI and CMI, addresses safety concerns, and reduces long-term operational risk.

Cost/Benefit Summary
While Alternative 1 requires a higher initial investment, it provides the greatest long-term value by:

Reducing outage duration and customer impact
Lowering emergency O&M and fail-order activity
Improving system safety and maintainability
Aligning with the company's vintage underground replacement strategy and rate-case reliability objectives



Conceptual Estimate

Program	Notification#	Loaded Cost	Plan Year	Description
2.16 Lines Rehabilitation - LVD	1072892823	$ 2053901	2027

Open Point
All primary should be 1/0 Al, and all services should be at least 350 Al.
Wherever possible, please place a secondary cabinet at least every 4 services.
Please design for New Business voltage drop and flicker.
The black outlines are the assumed areas of service for each transformer.
This section of secondary will be replaced in a Fail order. Not: 1072824896
If physically possible, please add this tie point to the neighboring loop

Notes

{a} Amortization Expense for Campbell Units 1&2 reflects the previously approved (in U-21585 and U-21870) annual amortization expenses through April 30, 2027. The total amortization expense for the projected test year period ending April 30, 2028 is $72,543, which represents the annual straightline amortization required to fully amortize the remaining regulatory asset balance to zero over its originally approved life ending in May 2031

{b} Amortization Expense for Campbell Unit 3 reflects the previously approved (in U-21585 and U-21870) annual amortization expenses through April 30, 2027. The total amortization expense for the projected test year period ending April 30, 2028 is $55,553, which represents the annual straightline amortization required to fully amortize the remaining regulatory asset balance to zero over its originally approved life ending in May 2040.

[A] Electric information contained herein includes amounts associated with transmission assets, which are subject to rate regulation by the Federal Energy Regulatory Commission ("FERC"). On September 13, 2022, FERC issued a final order in Docket #ER22-2597-000 requiring $1,895,000 of TCJA-related excess deferred federal income taxes associated with transmission assets be refunded to transmission customers. This amount is reflected in column 2-A and reduced the Regulatory Asset/(Liability) due to customers as it will be refunded subject to the FERC order.

[B] In its original U-20309 filing, the Company inadvertently included in its unprotected plant balance a remeasurement of excess deferred taxes associated with AFUDC timing differences. A subsequent reconcilation of the 2019 TCJA balance highlighted this discrepancy. The Company reflected this proposed change in Case No. U-21224 and the Commission subsequently approved the adjustment in it's January 19, 2023 order.

[C] Gross-up change to the regulatory liability balance due to a statutory or apportionment rate change.

[D] Included in Case No. U-21224.

[E] Included in Case No. U-21389

[F] Included in Case No. U-21585

[G] Included in Case No. U-21870

Covert Station Static Frequency Converter Replacement

Date: 9/24/2024

Prepared by: Paul Ohep

Figure 1. Covert Generating Station

Executive Summary

The Covert Generating Station (CGS) Static Frequency Converter (SFC) Controls Replacement project addresses critical operational and reliability issues due to the obsolescence of the current SFC controls. This project is essential for maintaining the operational integrity and reliability of the plant's turbine generators, which rely on the SFCs for startup.

Problem Description: The existing SFC controls, which are nearly 25 years old, pose a high risk of failure. Engineering estimates indicate a 30% failure probability for these electronic components, increasing by 15% annually. The failure of both SFCs would prevent the startup of any unit at CGS, resulting in a total operational shutdown and significant financial losses. Mitsubishi, the Original Equipment Manufacturer (OEM), strongly recommends replacing the controls and other obsolete components, highlighting the urgency of this project.

Alternative Solutions:

1. **Do Nothing**: This option poses significant risks, including a potential $125,884,384 financial impact due to forced outages and capacity losses. The high probability of failure of the obsolete controls could result in prolonged outages, severely impacting the plant's operational integrity and financial stability.
2. **Replace Controls on Both SFCs During 2026 All-Unit Outage**: This option eliminates the immediate risk of failure, restores system reliability, and saves costs by performing both replacements simultaneously during the planned 2026 outage. The estimated cost is $4,466,000.
3. **Replace Controls on One SFC in 2026 and the Second in 2032**: This phased approach mitigates some immediate risks but retains reliance on aging controls until 2032. It incurs higher overall costs ($6,185,000) and repeated operational disruptions, increasing the risk of failures and financial losses.

Selected Option Justification: Chosen Option: Alternative 2 – Replace both SFC controls and obsolete equipment during the 2026 all-unit outage.

Rationale for Selection: Alternative 2 is the lowest cost and most risk-averse option, addressing critical obsolescence issues comprehensively. This approach ensures the reliability of the SFC system until the plant's anticipated closure.

Conclusion: Replacing the controls on both SFCs during the 2026 all-unit outage is the most prudent and cost-effective approach. It comprehensively addresses the critical obsolescence issues, restores system reliability, and aligns with the planned maintenance schedule, minimizing operational risks and ensuring the plant's continued efficiency and reliability.

Financial Summary

Funding Type:	Capital
Estimated Total Cost:	$5,000,000

Proposed Start Implementation Year and Duration

Implementation Year: 2026

Problem Description

Project Overview

The Covert Generating Station (CGS) Static Frequency Converter (SFC) Controls Replacement project is essential to address significant operational and reliability issues stemming from the obsolescence of the current SFC controls. This project is critical for maintaining the operational integrity and reliability of the plant's turbine generators, which rely on the SFCs for startup.

Background

To initiate the combustion turbine at CGS, the attached generator is used as a motor to start spinning the turbine generator train. The Static Frequency Converter provides variable power to the generator stator, enabling this startup process. The SFC system includes a converter, a DC reactor, and an inverter, controlled by a generator position sensor to ensure smooth acceleration and prevent overheating of the generator windings.

The plant operates with two SFCs, SFC #1 and SFC #2, both original to the plant's construction in 2001. These converters are connected to all three gas turbine generators at the site. The current system relies on visual inspections during outages to monitor overheating, which is insufficient for proactive maintenance.

Necessity for Replacement

The necessity for replacing the SFC controls arises from their advanced age and increasing risk of failure. Key points include:

- **Obsolescence and Risk of Failure**: The SFC controls are nearly 25 years old, and the probability of failure for electronic components increases significantly over decades of use. Engineering estimates indicate a 30% failure probability for any of the 20+ year old electronic components, with this probability increasing by 15% annually. The high risk of failure is due to the nature of aging electronics, which are prone to degradation over time.
- **Operational Impact**: If one SFC fails, the plant can rely on the second SFC. However, if both SFCs fail, the plant will be unable to start any unit, resulting in a complete operational shutdown. Given the critical role of the SFCs in plant operations, their failure poses a substantial risk.
- **Lead Time for Repairs**: In the event of a controls failure, an SFC could be out of service for over a year due to the long lead time for obtaining replacement parts. During this period, the second SFC, which shares the same risk of failure, could also fail, leading to a total inability to start any units at CGS.
- **Vendor Recommendations**: Mitsubishi, the Original Equipment Manufacturer (OEM), strongly recommends replacing the controls and other obsolete components (such as cooling fans), which are no longer serviceable. This recommendation highlights the urgency and necessity of the replacement project.
- **Scheduled Outages**: Replacing the SFC controls requires an all-unit outage of sufficient duration (20 days) to ensure worker protection and complete the work. These outages are scheduled roughly every six years, with the next planned outages in 2026, 2032, and

2038. Coordinating the replacement with the 2026 outage minimizes disruption and ensures continued reliability.

In summary, the replacement of the SFC controls is imperative to mitigate the significant risk of failure due to obsolescence, ensure operational reliability, and align with manufacturer recommendations.

Alternative Solutions/Alternatives Considered

1. Do Nothing – Potential costs up to $125,884,384.

Choosing the "do nothing" option for the Covert Generating Station (CGS) Static Frequency Converter (SFC) Controls Replacement project means maintaining the status quo despite the known obsolescence issues and high risk of failure. This section outlines the potential consequences, including derates, forced outages, and financial impacts, of not executing the replacement project.

Derate and Outage Impacts

- **Derate in MW**: If the SFC controls fail and neither SFC is operational, there would be a total derate of 1289 MW. This includes the inability to start up:
    - Three gas turbines at 282.2 MW each.
    - Three steam turbines at 147.39 MW each.
- **Duration of Derate/Outage**:
    - The initial failure of one SFC would lead to a minimum site-wide, two-week forced outage. This is necessary to disconnect and test other equipment connected to the SFC (such as generators and exciters) to ensure they remain functional, and to re-arrange the bus work so the plant can continue operating with the working SFC while repairs are made to the failed one.
    - Mitsubishi has indicated that given the obsolescence nature of the system the lead time for new controls exceeds one year. During this period, the second SFC is at risk of failing from the same cause, which would prevent the start-up of any units at CGS and extend the outage indefinitely until parts are procured and installed.

Risks of Failure

- **Probability and Consequences**:
    - Engineering estimates indicate a 30% failure probability for any of the 20+ year old electronic components, with this probability increasing by 15% annually.
    - If both SFCs fail, no units at CGS can start, resulting in a complete operational shutdown.

Financial Risk - $7,791,000 for a single SFC failure, $125,884,384 for dual SFC failure

- **Net Energy Value (NEV) losses**:
    - **One SFC failure**: It is expected that this failure will cause a two-week forced outage for all three units, resulting in a reduction of power supply by 1,289 megawatts. This case assumes the outage to take place during the first two weeks of July, which is the same time as the yearly highest demand for power, representing a scenario with the most challenging conditions. The energy value losses calculated for this scenario are estimated to be $**1,280,000** per unit or $**3,840,000** for the entire site.

- **Dual SFC failure**: A one-year forced outage is assumed for this case. The station would then incur a loss of **$7,961,461** per unit or **$23,884,384** for the entire site (all three units).

  The gas prices used the economic model are based on the 2024 0+12 commodity price outlook model.

- **Potential Capacity losses**: Based on the analysis provided by the forecasting group at Consumers Energy, the potential capacity losses for not proceeding with the SFC controls replacement project are quantified for both the one SFC failure scenario and for both SFC failing:

  - **One SFC failure**: A two-week forced outage is assumed for this case. The station would incur a loss of **4.6 Zonal Resource Credits (ZRCs)** per unit annually for three years. This loss translates to a financial impact of approximately **$439K per year per unit or $1,317,000 for the site**, culminating in a total loss of **$3,951,000** over the three-year period for the entire site (all three units). This calculation is based on 4.6 ZRCs multiplied by 75% of $127K (the Cost of New Entry), a benchmark figure representing the hypothetical cost to build a new power plant.

  - **Dual SFC failure:** In a more severe scenario where the CGS loses its full capacity for an entire year due to both SFCs failing, the financial repercussions are even more pronounced. The loss is estimated at 75% of the CONE multiplied by 360MW (nameplate capacity per unit), amounting to **$34 million per unit or $102 million for the entire site**.

  - The Midcontinent Independent System Operator (MISO) capacity pricing rules dictate that utilities must maintain a certain level of capacity to ensure grid reliability. ZRCs are a measure of this capacity, and their loss indicates a shortfall in the utility's ability to meet demand, potentially leading to penalties and reduced revenue. The CONE is used to set capacity prices in the market, and the percentage applied (75% in this case) reflects the proportion of this cost considered in financial calculations, often influenced by regulatory guidelines or market conditions.

Timing of Derate or Forced Shutdown

- The timing of the derate or forced shutdown is irrelevant in this case because the plant cannot start without at least one functional SFC. The operational impact would be severe regardless of the season, as the SFCs are critical for startup operations year-round.

Conclusion

In summary, the "do nothing" option poses significant risks to the operational integrity and financial stability of the Covert Generating Station. The high probability of failure of the obsolete SFC controls, coupled with the extended lead times for replacement parts, could result in prolonged outages and substantial financial losses. This quantifiable risk justifies the need for proactive replacement of the SFC controls to ensure continued reliability and efficiency of plant operations.

Option 2: Replace Controls on Both SFCs During All Unit outage in 2026 – Cost: $5,000,000 (internal loaded estimate)

Alternative 2 proposes replacing the controls on both Static Frequency Converters (SFCs) during the planned all-unit outage in 2026. This approach presents the lowest risk by taking advantage of the scheduled outage to address the obsolescence issues comprehensively, ensuring the reliability of the SFC system until the anticipated plant closure.

Benefits

- **Reduced Risk**: By replacing the controls on both SFCs simultaneously, this option eliminates the immediate and growing risk of failure associated with the aging and obsolete controls. It addresses the critical vulnerability of relying on outdated electronic components that have a high probability of failure.
- **Cost Savings**: Performing the replacements during a planned outage allows for cost efficiencies. Mobilizing once for both replacements reduces labor, transportation, and other logistical expenses. The estimated loaded cost for replacing the controls on both SFCs is $5,000,000 (internal estimate based on Turnkey quote from Vendor).
- **Enhanced Reliability**: Upgrading both SFC controls ensures the plant can reliably start its units without the risk of unexpected failures. This proactive maintenance will restore the SFC system's reliability, supporting stable operations until the plant's anticipated closure.
- **Efficiency and Coordination**: Utilizing the 2026 outage for this replacement aligns with the plant's maintenance schedule, minimizing disruption.

Conclusion

Replacing the controls on both SFCs during the 2026 all-unit outage is the most prudent and cost-effective approach. It addresses the critical obsolescence issues, restores system reliability, and aligns with the planned maintenance schedule, thereby minimizing operational risks and ensuring the plant's continued efficiency and reliability.

Option 3: Replace Controls on One SFC During 2026 All-Unit Outage, Then Wait Until 2032 to Replace the Second SFC Controls – Cost $6,185,000

Alternative 3 involves a phased approach where the controls for one Static Frequency Converter (SFC) are replaced during the all-unit outage in 2026, with the second SFC controls being replaced during the next scheduled outage in 2032. While this option addresses some of the immediate risks associated with the obsolescence of the SFC controls, it retains reliance on the aging system for an extended period, which may compromise reliability and increase costs over time.

Benefits

- **Reduced Immediate Risk**: Replacing the controls on one SFC during the 2026 outage mitigates some of the risk associated with the current obsolete controls, ensuring at least one SFC is updated and reliable.
- **Staggered Investment**: This approach spreads the financial burden over two planned outages, potentially easing the immediate capital expenditure.

Drawbacks

- **Continued Reliability Risks**: By delaying the replacement of the second SFC controls until 2032, the plant remains dependent on the aging and increasingly unreliable controls for another six years. Given the failure probabilities detailed in the problem statement and do-nothing sections, we expect a failure sometime before 2032. This means the site will likely face a forced two-week outage just to check all other connected equipment and align the remaining SFC to the second unit, assuming the new upgraded system is compatible with the existing components. This shutdown would result in considerable losses in Net Energy Value and potential capacity, as detailed in the "Do Nothing" section.
- **Repeated Costs and Efforts**: This option incurs repeated mobilization and logistical costs associated with conducting two separate replacement projects. The total anticipated cost for both replacements is $6,185,000, which is higher than replacing both controls simultaneously in 2026.
- **Potential Cost Escalation**: Delaying the replacement of the second SFC controls exposes the project to potential cost increases due to inflation and changes in market conditions over the next six years.
- **Operational Disruptions**: Each replacement phase requires an all-site outage, leading to repeated operational disruptions and potential loss of productivity.

Conclusion

While Alternative 3 offers a phased approach to spreading the cost over two outages, it introduces significant risks and additional costs. The continued reliance on obsolete controls until 2032 increases the likelihood of failures and operational disruptions. The overall cost of $6,185,000 is higher compared to replacing both controls simultaneously in 2026. This option

presents a higher risk and less cost-effective solution compared to Alternative 2, which provides a comprehensive and more reliable approach to addressing the obsolescence issues at CGS.

Recommended Alternative: #2 Replace both SFC controls and obsolete equipment.

Rationale for Selection

Alternative 2 has been selected for implementation as it represents the lowest cost and most risk-averse option. This approach ensures the reliability and operational integrity of the Static Frequency Converters (SFCs) at Covert Generating Station by addressing their obsolescence comprehensively during the planned all-unit outage in 2026.

Outcomes and Benefits

Outcomes:

1. **Planned Restoration of Reliability**: Both SFCs will have their controls replaced by the end of 2026, addressing obsolescence before failure occurs.
2. **Replacement of Problematic Speed Sensor**: The historically troublesome speed sensor will be replaced, eliminating startup delays that currently range from 1-4 hours per instance.
3. **Testing of Aged Power Cable**: The aged power cables of the SFCs will be tested to verify their reliability through the end of the plant's life.

Benefits:

1. **System Reliability**: Restores the entire SFC system to a reliable state from its current obsolete condition by 2026.
2. **Cost Efficiency**: Utilizing the same craft and engineers for both SFC replacements simultaneously saves costs compared to mobilizing separately for each unit.
3. **Operational Efficiency**: Performing the replacements at the same time minimizes disruption and leverages the planned outage effectively, ensuring reliability through the end of the plant's life.
4. **Error Mitigation**: Avoids the potential for errors associated with staggering the replacements, as the same team will work on both units, maintaining consistency and reducing execution risk.

Highlighted Benefits Over Other Alternatives

The main benefit of Alternative 2 is the comprehensive restoration of reliability to both SFCs by 2026, ensuring continuous operation through the plant's lifecycle. This approach avoids the significant risks and higher costs associated with Alternative 3, which involves staggering the replacements and potentially facing a forced outage due to the high probability of failure in the remaining obsolete controls.

Working on both SFCs during the 2026 outage not only provides cost savings by avoiding repeated mobilization but also ensures that the replacements are handled by the same team, enhancing consistency, and reducing the risk of errors. This approach mitigates the operational risks and financial losses that could occur with a phased replacement strategy, ultimately providing a more secure and cost-effective solution for maintaining the plant's reliability and efficiency.

Scope of work

1. **Preparation (2025-2026)**:
    - Engineering and project management activities will begin in 2025 to ensure all necessary plans, parts, and personnel are in place for the 2026 outage.
    - Coordination with Mitsubishi and other vendors to secure parts and finalize the replacement schedule.
2. **Execution (2026)**:
    - During the all-unit outage in 2026, the existing SFC controls will be removed, and new controls will be installed.
    - Testing and commissioning of the new controls will be conducted to ensure seamless integration and operation.
3. **Closeout (2026)**:
    - Final inspections and closeout activities will be completed to confirm the successful implementation of the project.
    - Documentation and reporting will be finalized to capture all aspects of the replacement for future reference and compliance.

Funding and Timing

- A planned outage is required for this project.
- Desired implementation year:
    - First year spend: 2024
    - Implementation: 2026

System Engineer

- System Engineer: Keith Grzegorczyk

Conceptual Estimate

Year	Loaded Cost	Description
2024	**$130,000**	Generation Planning places retrieves quote and places PO for very long lead time parts.
2025	**$520,000**	EPM starts drawing engineering, outage scheduling, and labor PO.
2026	**$4,350,000**	Parts receipt, construction, and closeout.

Total Cost: $ 5,000,000

Asset Strategy Approval Comments

This project at the Covert Generating Station **is** recognized in the 2023 electric rate case, not as a standalone item but within the broader category of non-LTSA (Long Term Service Agreement) projects. This categorization reflects the strategic allocation of funds for various essential undertakings at Covert, following its recent acquisition.

The allocated budget under work item 1218, titled “Covert -Non LTSA Capital - Extras not included in contract,” encompasses this and other similar projects. The figures covered under this line item are as follows:

Amount set for Bridge year: $ 3,943,000

Amount set for test period: $ 5,510,000

Covert Generating Station Generator Step-Up transformer replacement.

Date: 12/1/2023

Prepared by: John Slinkard and Paul Ohep

Figure 1. Covert Generating Station aerial view.

Executive Summary

Addressing the critical need for operational reliability at Consumers Energy's power generation facilities, this proposal explores the optimal strategy for ensuring a backup Generator Step-Up (GSU) transformer is readily available at Covert Generating Station. The urgency of this project stems from the increased risk of transformer failure due to the presence of corrosive sulfur, coupled with long procurement lead times of 2 to 4 years for GSU transformers.

Four options were meticulously evaluated: overhauling the existing GSU, procuring a new site-specific spare GSU, exploring leasing alternatives, and purchasing a single larger spare GSU that could serve both Covert Generating Station and Zeeland Generating Station.

Option 2, which proposes the procurement of a site-specific spare GSU, has emerged as the most viable solution. It ensures immediate availability of a replacement transformer, minimizing downtime and associated financial losses. This option mitigates potential complications arising from multiple installations associated with utilizing a leased GSU or usage of multi-site transformer. Moreover, it also offers the opportunity for CE to recover some costs through leasing agreements with other utilities.

This initiative, backed by the Asset Strategy Group, ensures that Covert Generating Station is equipped to address transformer failures swiftly and efficiently. Implementing this solution safeguards our ability to deliver reliable power to our consumers and demonstrates a strategic foresight in asset management.

Financial Summary

Funding Type:	Capital
Estimated Total Cost:	$16,355,000

Proposed Start Implementation Year

2024

Project Span Whole Years

4 Years

Problem Description

The Covert Generating Station features a combination of three gas turbine-powered plants and three steam turbine-powered plants, arranged in a one-on-one combined cycle configuration. This setup entails that each gas turbine unit powers the secondary winding of a three-winding transformer (GSU), while the corresponding steam-powered unit powers the tertiary winding.

GSU Explained: A Generator Step-Up (GSU) transformer is a critical component that steps up the voltage generated by a turbine before it is transmitted to the grid, ensuring efficient power transfer.

A GSU's failure can lead to significant power generation issues. Specifically, the GSUs at Covert are rated for 500 MVA and are equipped with forced oil and forced air cooling mechanisms. If a GSU were to fail, both the gas and steam turbine units connected to it would be unable to transmit power, leading to a potential loss of up to 400 MVA of generation capacity. This would prevent the generation of market value for Consumers Energy and its customers.

Further complicating the situation is the long lead time of 2 to 4 years for procuring a replacement GSU, and the lack of spare units at other facilities. The plant is projected to operating until at least 2040, thus making it crucial to have a reliable GSU ready for replacement.

Figure 2. Typical Step-Up transformer

Alternative Solutions/Alternatives Considered

1. Do Nothing – Cost: $130.9 million ($16.4M for new GSU plus $114M in energy value and potential capacity lost)

This approach involves continuing the operation without procuring a spare GSU, essentially accepting the risks associated with a potential GSU failure. When under load, a failure of the GSU transformer is a serious concern, not only because of the high financial costs but also due to safety implications. Such a failure could lead to cascading consequences where other critical equipment, such as the generator or the 345kV breaker, could be damaged or fail.

The GSU transformer is a critical component, and its failure would render the combined plant, consisting of one steam turbine and one gas turbine, inoperative. An overhaul or replacement of a GSU transformer, in the event of a failure, is expected to take a minimum of 12 months.

There is an estimated 20% risk that the generator or the 345kV breaker might be damaged during an in-service failure of a GSU. The replacement cost for the generator is estimated at $20M and for a 345kV breaker, it is around $1M. These costs are not included in the alternative cost.

The economic considerations for not having a spare GSU transformer on site, with an anticipated downtime of a full year, are significant. The breakdown for both potential capacity lost, and average energy value lost are as follows:

Capacity value potential loss impacts - $66.6M:

For this option, where the procurement and installation of the new GSU transformer are involved, a critical consideration is the multi-year financial impact, as determined by the Midcontinent Independent System Operator (MISO). MISO calculates and accredits capacity based on a rolling three-year average of historical capacity credits. Therefore, any outage that exceeds the 30-day threshold can significantly affect these calculations.

Given the expected duration of the entire process is about one full year, this threshold will be exceeded. This prolonged downtime will, therefore, trigger the multi-year financial impact, altering the capacity accreditation and potentially affecting financial projections for several years.

Average ZRC Reduction Post-Outage:

- In the event of a 365-day outage, the projected average Zonal Resource Credits (ZRCs) for the following three years, assuming no further outages exceeding 30 days, is expected to be around 236 ZRC per year for each season (based on 354 ZRCs per season).
- This scenario leads to a potential annual daily loss of 118 ZRCs per season for each of these three years (354 ZRCs-236 ZRCs).

2. **Cumulative Potential Loss of Capacity Value Over Three Years:**
    - The total potential loss of capacity value combines the immediate impact of 354 ZRCs during the 365-day outage and the additional 118 ZRCs/day applied over 90 days times four seasons over the subsequent three years.
3. **Calculation of Total Potential Loss:**
    - To estimate the potential capacity loss for this option:
        1. Calculate the Reduced Capacity Credits:
            - We start by finding the difference between the average number of Zonal Resource Credits (ZRCs) the plant earned over the last three years (236 in this case) and the maximum possible ZRCs of 354.
            - Multiply this difference (118) by 90 days (full season impact), and then again by 3 years. This gives us the total reduction in capacity credits over three years due to the outage (31,860).
        2. Add the Immediate Loss:
            - Next, multiply the number of days the plant is offline (that season) by the total ZRCs lost in that season (354 in this case). This gives us the immediate loss in capacity credits for that outage (31,860).
        3. Calculate the Total Revenue Loss:
            - Add the results from steps 1 and 2 to get a combined figure (63,720).
        4. Finally, multiply this combined figure by 75% of the daily Cost of New Entry (CONE) rate, which is $261.24. (This is based on the yearly CONE rate of $127,135.)
    - This leads to a total estimated potential loss of capacity value of an estimated $16.6 million per season over the three-year period following the outage.
    - The total potential capacity value impact for a one-year outage, accounting for all four seasons, and including the impact on the subsequent three years is given by multiplying $16.6 million times four, resulting in an estimated $66.6 million potential impact.

<u>Average energy value estimated loss - $47.9M:</u>

For the scenario of a transformer failure with no spare on-site, there is a substantial potential loss in energy production due to an assumed 365-day outage. This loss can be quantified by considering the Net Energy Value (NEV) for that station.

Net Energy Value (NEV): The NEV, a measure of the gross energy value minus the total costs for a particular generating station, is $47.9M per year for the Covert Station.

This figure represents the potential average revenue loss for the Covert Generating Station during the outage period.

This analysis emphasizes the potential financial impact of not having a spare GSU on-site. Considering both the immediate potential loss of capacity value due to the outage, the reduced capacity credits in the subsequent three years as well as the energy value lost.

Overall advantages and disadvantages:

- **Advantages:** There is no immediate expenditure or need for storage.
- **Disadvantages:** This approach carries the highest long-term cost and risk, including the potential loss in revenue, safety hazards, and extended downtime for repairs or replacements.

2. Procure and Store a Spare GSU on-site Cost: $31.7M (including $15.3M in potential capacity value and energy value losses)

This alternative solution involves the strategic decision of procuring and maintaining a spare GSU transformer at the plant site.

- The procurement cost of the spare GSU is quoted at $12.5 million, based on an estimate from a well-known manufacturer of power transformers.
- The cost of constructing an appropriate foundation at the Covert site for the spare GSU is projected to be $200,000, as estimated by a specialized civil engineering company.
- Additional expenses related to engineering, Stand Up Transformer (SUT), and other logistical aspects are anticipated to be around $280,000.
- In the cost estimation process for large capital projects, it is a common industry practice to incorporate budget to account for unforeseen expenses that might occur during the project. The typical industry standard for such budgets can vary from 5% to 10% of the total project cost, depending on the project's complexity and risk level. For this specific project, we have included a conservative budget of 5% to the total estimated cost, considering our high predictability and control over project variables. Additionally, to cover regular operational and administrative expenses related to the project, a 20% overhead has been factored in. Consequently, the comprehensive cost estimate for this option now stands at $16.355 million (internal estimate).
- The economic considerations for procuring a spare GSU for the Covert Generating Station, with an assumed downtime of 31 days, are significant but more manageable when compared to leasing.

The breakdown for potential capacity lost, and average energy value lost are as follows:

Capacity value potential loss impacts - $11.2M:

For this option, the installation of the new GSU transformer stored on-site is anticipated to take approximately 30 days or slightly more. Specifically, if an outage exceeds 30 days, it triggers a potential multi-year financial impact due to the way MISO calculates and accredits capacity over time.

In this scenario, we will assume a worst-case scenario outage duration of 31 days within a single season. This results in the Station losing all 354 ZRCs (Zonal Resource Credits) for the season. This loss of ZRCs would result in a multiyear capacity impact, as capacity accreditation by MISO is based on a three-year average of historical capacity credits. It is important to note that if the outage had been limited to 30 days or less, or if the outage spans across parts of two separate seasons there would be no loss of ZRCs for either season, and consequently, no capacity impact.

Average ZRC Reduction Post-Outage:

- In the event of a 31-day unplanned outage during a single season, the projected average Zonal Resource Credits (ZRCs) for the following three years, assuming no further outages exceeding 30 days, is expected to be around 236 ZRC per year for that season (based on 354 ZRCs per season).
- This scenario leads to a potential daily capacity loss of 118 ZRCs across an entire season (90 days) for each of these three years (354 ZRCs-236 ZRCs).

Calculation of Total Potential Loss:

- The total potential loss of capacity value combines the immediate impact of 354 ZRCs during the 31-day outage and the additional 118 ZRCs/day applied over 90 days (full season) over the subsequent three years.
- To estimate the potential capacity loss for this option:
    1. Calculate the Reduced Capacity Credits:
        - We start by finding the difference between the average number of Zonal Resource Credits (ZRCs) the plant earned over the last three years (236 in this case) and the maximum possible ZRCs of 354.
        - Multiply this difference (118) by 90 days (full season impact), and then again by 3 years. This gives us the total reduction in capacity credits over three years due to the outage (31,860).

2. Add the Immediate Loss:
    - Next, multiply the number of days the plant is offline (that season) by the total ZRCs lost in that season (31 x 354 in this case). This gives us the immediate loss in capacity credits for that outage (10,974).
3. Calculate the Total Revenue Loss:
    - Add the results from steps 1 and 2 to get a combined figure (42,834).
4. Finally, multiply this combined figure by 75% of the daily Cost of New Entry (CONE) rate, which is $261.24. (This is based on the yearly CONE rate of $127,135.)

- This leads to a total estimated potential loss of capacity value of an estimated $11.2 million over the three-year period following the outage.

<u>Average energy value estimated loss – $4.1M:</u>

For the Covert Generating Station, under the scenario of leasing a spare GSU, there is a substantial potential loss in energy production due to an assumed 31-day outage. This loss can be quantified by considering the Net Energy Value (NEV) of the station.

Net Energy Value (NEV): The NEV, a measure of the gross energy value minus the total costs for a particular generating station, is $47.9M per year for the Covert Station.

Calculation of Total Average Energy Loss:

- The loss in energy production is calculated over the 31-day outage period.
- This results in a total average energy loss of an estimated $4.1 million. (($47.9M/year)/(365days/year)) x 31 days = $4.1M

This figure represents the potential average revenue loss for the Covert Generating Station during the outage period.

<u>On-site spare overall advantages and disadvantages:</u>

Advantages:

- Having a spare GSU on-site ensures rapid restoration of operations in case of a failure, thereby minimizing revenue losses.

Disadvantages:

- The approach necessitates a sizable upfront investment and requires additional storage space on-site.

3. Leasing a GSU Transformer - $36.8M in energy and potential capacity losses plus $720,000 over 20 years ($36,000/year):

This alternative explores the feasibility of entering into a lease agreement for a GSU transformer. Leasing for units of this size is a standard approach, often entailing a reservation fee of an estimated $3,000 per month. Over a span of 20 years, which is the expected life expectancy of such units, the total cost amounts to $720,000. This translates to an annual expense of an estimated $36,000. However, leasing comes with certain conditions and restrictions:

- The owner of the leased equipment can request the unit back at any point, based on their requirements.
- Availability is not guaranteed as the unit may not be on hand when needed. An industry search and examination of the transformer strategic reserve indicated that there are currently no spare units available for lease.
- Potential capacity value and energy value impacts.

Capacity value potential loss impacts - $25.0M:

For the leasing option in the GSU project, we are assuming the occurrence of an unplanned outage at the most inopportune time, specifically a scenario where a 90-day outage spans across two MISO seasons. The outage is projected to last for 31 days in one season, with the remaining duration extending into the next season. This situation results in the loss of Zonal Resource Credits (ZRC) capacity value for two separate seasons, which, due to MISO's capacity accreditation method based on a three-year historical average, effectively doubles the amount of lost capacity value over the next three years.

Average ZRC Reduction Post-Outage:

- In the event the postulated scenario, the projected average Zonal Resource Credits (ZRCs) for the following three years, assuming no further outages exceeding 30 days, is expected to be around 236 ZRC per year for that season (based on 354 ZRCs per season).
- This scenario leads to a potential daily capacity loss of 118 ZRCs across an entire season (90 days) for each of these three years (354 ZRCs-236 ZRCs).
- For the unplanned 90-day outage spanning across two seasons assumed in this case, the 354 ZRCs will be multiplied times two to yield 708 ZRCs.

Calculation of Total Potential Loss:

- The total potential loss of capacity value combines the immediate impact of 354 ZRCs during the first 31-day outage in one season and then for the 59-

day outage on the following season. It also adds 118 ZRCs/day applied over 90 days (full season) over the subsequent three years.

- To estimate the potential capacity loss for this option:
    1. Calculate the Reduced Capacity Credits:
        - We start by finding the difference between the average number of Zonal Resource Credits (ZRCs) the plant earned over the last three years (236 in this case) and the maximum possible ZRCs of 354.
        - Multiply this difference (118) by 90 days (full season impact), and then again by 3 years. This gives us the total reduction in capacity credits over three years due to the outage (31,860).
        - This result is multiplied times two to account for the impacts to a second season. (63,720)
    2. Add the Immediate Loss:
        - Next, multiply the number of days the plant is offline by the total ZRCs lost (354 in this case). This gives us the immediate loss in capacity credits for the 90-day outage (31,860).
    3. Calculate the Total Revenue Loss:
        - Add the results from steps 1 and 2 to get a combined figure (95,580).
    4. Finally, multiply this combined figure by 75% of the daily Cost of New Entry (CONE) rate, which is $261.24. (This is based on the yearly CONE rate of $127,135.)
- This leads to a total potential loss of capacity value of an estimated $25.0 million over the three-year period following the outage.

<u>Average energy value estimated loss - $11.8M:</u>

For the Covert Generating Station, under the scenario of leasing a spare GSU, there is a substantial potential loss in energy production due to an assumed 90-day outage. This loss can be quantified by considering the Net Energy Value (NEV) of the station.

Net Energy Value (NEV): The NEV, a measure of the gross energy value minus the total costs for a particular generating station, is $47.9M per year for the Covert Station.

Calculation of Total Average Energy Loss:

- The loss in energy production is calculated over the 90-day outage period.
- This results in a total average energy loss of an estimated $4.1 million. (($47.9M/year)/(365days/year)) x 90 days = $11.8M

Leasing option overall advantages and disadvantages:

Advantages: Leasing could offer a lower upfront cost compared to purchasing a new or spare unit outright.

Disadvantages:

- Unpredictable Availability: The availability of a leased GSU is uncertain, which can pose a significant operational risk.
- Recall Risk: There's always a possibility that the unit's owner may recall the GSU at any time, potentially causing unplanned operational downtime.
- Financial Risk: In the event of a plant shutdown due to the unavailability of a GSU, there could be a substantial financial impact.

4. Purchasing a Larger, Multi-Site GSU Transformer – Cost: $58M - $27.4M plus $30.6M in potential capacity and energy value losses:

This alternative considers purchasing a single larger spare GSU transformer that is suitable for both Zeeland Generating Station (ZGS) and Covert Generating Station (CGS). Internal economic models project the final costs to be estimated at $58M when factoring in additional expenses such as reinstallation of original overhauled GSU, modifications needed to accommodate the larger GSU at ZGS, additional outage costs and potential capacity and energy value losses. The breakdown of the internal estimate includes:

- $14M for the larger GSU transformer.
- $3M for transportation from another site and modifications needed at ZGS to accommodate bigger transformer.
- $1.25M for design and installation needs.
- $4.1M overhaul and re-installation cost of original GSU.
- $3.75M overhead estimate.
- $1.3M contingent cost to ensure compatibility with the original infrastructure. (5%)

Financial impacts:

For this option, which involves utilizing a common spare GSU for both Covert and Zeeland Generating Stations, several scenarios need to be considered to understand the financial implications fully. These scenarios vary depending on where the spare transformer is stored, and which site experiences a transformer failure. For this analysis, the worst-case scenario is assumed: the spare transformer is staged at Covert Generating Station, and a failure occurs at Zeeland Generating Station's Phase 2 transformer.

Assumptions:

For the multi-site spare option of the GSU project, the approach assumes two distinct outages, each with different implications for potential capacity value losses:

1. **First Outage - Unplanned and Single Season:**
    - The first outage, lasting 31 days, is considered unplanned and is expected to occur entirely within a single MISO season.
    - As this outage exceeds the 30-day threshold, it results in the complete loss of Zonal Resource Credits (ZRC) capacity value for that season. This loss also impacts the subsequent three years due to MISO's method of calculating capacity credits based on a three-year historical average.
    - This initial outage accounts for the period required to replace a failed GSU with the spare transformer.
2. **Second Outage - Planned and Spanning Two Seasons:**
    - The second outage, also spanning 31 days, is planned strategically to occur across the transition between two MISO seasons.
    - By dividing the outage between two seasons, each portion remains under the 30-day threshold in any single season, thereby avoiding additional ZRC capacity value penalties.
    - This outage involves reinstating the original GSU after its refurbishment, replacing the temporarily installed spare transformer.

<u>Capacity Value Potential Losses – $17.4M</u>

Average ZRC Reduction Post-Outage:

- In the event of a 31-day unplanned outage, the projected average Zonal Resource Credits (ZRCs) for the following three years, assuming no further outages exceeding 30 days, is expected to be around 366.7 ZRCs per year for that season (based on 550 ZRCs per season at Zeeland).
- This scenario leads to a potential daily capacity loss of 183.3 ZRCs across an entire season (90 days) for each of these three years (550 ZRCs-366.7 ZRCs).

Calculation of Total Potential Loss:

- The total potential loss of capacity value combines the immediate impact of 550 ZRCs during the first 31-day unplanned outage and the additional 183.3 ZRCs/day applied over 90 days (full season) over the subsequent three years.
- To estimate the potential capacity loss for this option:
    1. Calculate the Reduced Capacity Credits:

1. We start by finding the difference between the average number of Zonal Resource Credits (ZRCs) the plant earned over the last three years (366.7 in this case) and the maximum possible ZRCs of 550.
2. Multiply this difference (183.3) by 90 days (full season impact), and then again by 3 years. This gives us the total reduction in capacity credits over three years due to the outage (49,491).

2. Add the Immediate Loss:
   - Next, multiply the number of days the plant is offline (that season) by the total ZRCs lost in that season (550 in this case). This gives us the immediate loss in capacity credits for that outage (17,050).
3. Calculate the Total Revenue Loss:
   - Add the results from steps 1 and 2 to get a combined figure (66,541).
4. Finally, multiply this combined figure by 75% of the daily Cost of New Entry (CONE) rate, which is $261.24. (This is based on the yearly CONE rate of $127,135.)

This leads to a total estimated potential loss of capacity value of an estimated $17.4 million over the three-year period following the first unplanned outage.

For the multi-site spare option in the GSU project, the second outage is assumed to be planned to occur between MISO seasons. This careful timing ensures that the 31-day planned outage does not fall entirely within a single MISO season, thereby avoiding any loss of Zonal Resource Credits (ZRC) and potential capacity value.

Average energy value estimated loss - $13.2M:

For the Zeeland Generating Station, under the scenario of a multi-site spare GSU, there is a substantial potential loss in energy production due to two projected 31-day outages (62 total days). This loss can be quantified by considering the Net Energy Value (NEV) and the plant's generation capacity.

Net Energy Value (NEV): The NEV, a measure of the gross energy value minus the total costs for a particular generating station, is $77.5M per year for the Zeeland Phase 2 Station.

Calculation of Total Average Energy Loss:

- The loss in energy production is calculated over the 62-day total outage period.
- This results in a total average energy loss of an estimated $4.1 million. (($77.5M/year)/(365days/year)) x 62 days = $13.2M

This figure represents a significant potential revenue loss for the Zeeland Generating Station during the outage period.

Overall advantages and disadvantages for the multi-site spare option:

Advantages:

- **Flexibility**: A single spare unit could cater to multiple sites, potentially offering more operational flexibility.

Disadvantages:

- **Higher Costs**: The overall cost is significantly more than the initial purchase price when factoring in the additional work required.
- **Complexity**: This option could entail more logistical and operational complexities due to the constant movement and installation work.

Recommended Alternative: #2 – Purchase a spare Covert specific GSU

Option 2 emerges as the best long-term solution for ensuring a reliable spare GSU transformer at the Covert site. It eliminates dependencies on external variables and logistics that could influence the availability of the spare GSU. Additionally, the purchased unit could seamlessly be integrated as the new GSU at the location, thereby mitigating the need for multiple installations of temporary spares.

Project Benefits and Objectives:

1. **Reduction in Downtime and Financial Losses:** Opting for a dedicated spare GSU for Covert significantly reduces unit downtime in case of GSU issues or failures. This preemptive measure results in lowered financial losses during such events.
2. **Facilitation of Proactive Engineering Design and Planning:** Having a spare GSU readily available allows for easier engineering design and forward planning. This ensures that the installation of a spare or replacement GSU can be executed efficiently ahead of any emergent needs.
3. **Mitigation of Compatibility Issues:** This option mitigates potential challenges associated with installing GSUs not specifically designed for the Covert site, system, or application. It also prevents the complexities and risks of multiple installations within a short time.
4. **Revenue Recovery through Lease Agreements:** Owning a spare GSU provides Covert with the opportunity to enter lease agreements with other utilities that may require a spare, thereby enabling cost recovery over time.
5. **Addressing Increased Risk of Failure:** The oil analysis of Covert's transformers indicated the presence of chemicals for corrosive sulfur, putting them at an increased risk of failure. Having a spare GSU acts as a failsafe, ensuring continuity in operations while mitigating actions are taken.

Conclusion: Given the considerations, Option 2 proves to be strategically sound, financially prudent, and operationally efficient. It ensures reliability, provides contingency against unforeseen GSU failures, and aligns well with long-term planning objectives, making it the most favorable choice.

Scope of Work

The aim of this project is to ensure continuous operation at the Covert site by procuring and installing a spare Generator Step-Up (GSU) transformer that can be readily deployed at any GSU location within the facility.

Scope Description:

- **Procurement of Spare GSU Transformer:**
  The project entails defining the technical specifications for a compatible GSU transformer, initiating a procurement process, and ensuring quality assurance and compliance testing for the selected unit.
- **Infrastructure Development:**
  A dedicated foundation will be designed and constructed to facilitate quick installation of the transformer at any GSU location in Covert. This includes establishing a power supply and installing necessary accessories to maintain the transformer in an operational, "ready to use" condition.

Funding and Timing

- No funding has been previously committed for this project.
- No outage is required for this project.
- Desired implementation year: 2024
- Impact if the recommended implementation year is changed: Changing the recommended implementation year could lead to potential delays in addressing and mitigating the risks associated with GSU failures at the Covert site. Consequently, this may result in extended downtimes and increased financial losses, while also potentially jeopardizing the reliability of power supply from the plant.

System Engineer

- System Engineer: Keith R. Grzegorczyk

Conceptual Estimate

Year	Loaded Cost	Description
2024	**$1,765,000**	Project engineering for Spec/RFQ/Procurement activities/Pos to secure support, Initial payment.
2025	**$25,000**	Engineering and resource needs (no payments required to SMIT)
2026	**$4,763,000**	Estimated progress payment, construction of spare GSU storage foundation, engineering, quality assurance travel.
2027	**$9,802,000**	Final payment, delivery, construction of storage foundation, closeout.

Total Cost: $16,355,000

Asset Strategy Approval Comments

The Asset Strategy Group strongly recommends approval, given the challenges currently faced at Zeeland Station and Covert Station and the extended lead times for transformers, now ranging from 2 to 4 years. Ensuring that our key capacity plants have a spare GSU on hand is of utmost importance.

Covert Station Control Systems Upgrade

Date: 6/12/2024

Prepared by: Paul Ohep

Figure 1. Covert Generating Station

Executive Summary

Consumers Energy is undertaking a crucial control system upgrade at the Covert Generating Station, aimed at modernizing the existing infrastructure with advanced technological solutions. This initiative reflects our commitment to strengthening cybersecurity defenses, enhancing operational reliability, and maintaining regulatory compliance.

Project Justification and Compliance:

The upgrade follows a thorough assessment by our subject matter experts who identified significant vulnerabilities due to the use of outdated and unsupported control systems, currently operating on obsolete Windows Server platforms. These vulnerabilities expose the facility to substantial security risks, including potential cyber threats and data breaches. Following these findings, the cybersecurity leadership logged this issue as an existing risk with an assigned risk ID. This ensures continuous tracking and highlights the necessity for remediation efforts. This upgrade aligns with the CE Enterprise Patch Management Policy and fulfills the stringent requirements of the North American Electric Reliability Corporation (NERC) Critical Infrastructure Protection (CIP) standards, which emphasize regular updates and maintenance to safeguard control systems.

Financial Implications:

The total capital investment for this project is estimated at $20,042,000, including all associated loadings. This investment covers the costs of replacing hardware and software across all units at the Covert Station, transitioning to a virtualized server-based platform for all Human Machine Interfaces (HMIs) and control servers. The budget accounts for the installation of new, high-availability clustering servers, enhanced data storage solutions, and robust cybersecurity tools to protect against and manage future threats effectively.

Project Outcomes and Benefits:

Upon completion, the Covert Station will have a modernized control system architecture featuring:

- Enhanced cybersecurity measures to protect against unauthorized access and cyber-attacks.
- Increased operational reliability and efficiency using the latest hardware and software, supporting long-term operational goals.
- Compliance with current and anticipated regulatory requirements, mitigating the risk of non-compliance penalties.
- Improved system monitoring, control, and disaster recovery capabilities, ensuring continuous and secure plant operations.

Financial Summary

Funding Type:	Capital
Estimated Total Cost:	$20,042,000

Proposed Start Implementation Year and Duration

2024(first year spend), 2026(installation), 2027(closeout)

Problem Description

The Covert gas generating station, operational since 2004, faces critical challenges with its outdated control systems. These challenges impact both operational efficiency and cybersecurity, necessitating an urgent upgrade to modern standards.

Current System Overview

- **Control System Composition:** Utilizes the original Mitsubishi Netmation control system for turbine operations, integrated with Emerson Ovation DCS for Balance of Plant (BOP) auxiliary equipment.
- **System Age and Efficiency:** While typical gas-fired power plants are designed with a 30-year operational lifespan, their control systems often start experiencing issues around the 10-year mark. As these systems advance in their lifecycle, the incidence of operational problems tends to increase, particularly after reaching the 15th year. At this stage, upgrading the system often becomes more economically viable than continuing with repairs.
- Due to the extensive duration of service, the original control system components at the Covert Plant are experiencing repeated failures. These issues have been analyzed by our subject matter experts, who have determined that the components have surpassed the manufacturer's recommended operational timeframe. Based on these evaluations, our experts strongly recommend an upgrade to ensure reliable and efficient plant operation.
- As a result of these issues, the turbine control systems at the site are becoming prime candidates for a comprehensive update and replacement to ensure continued efficient and reliable operation. The figure below illustrates the control system timeline since its initial installation.

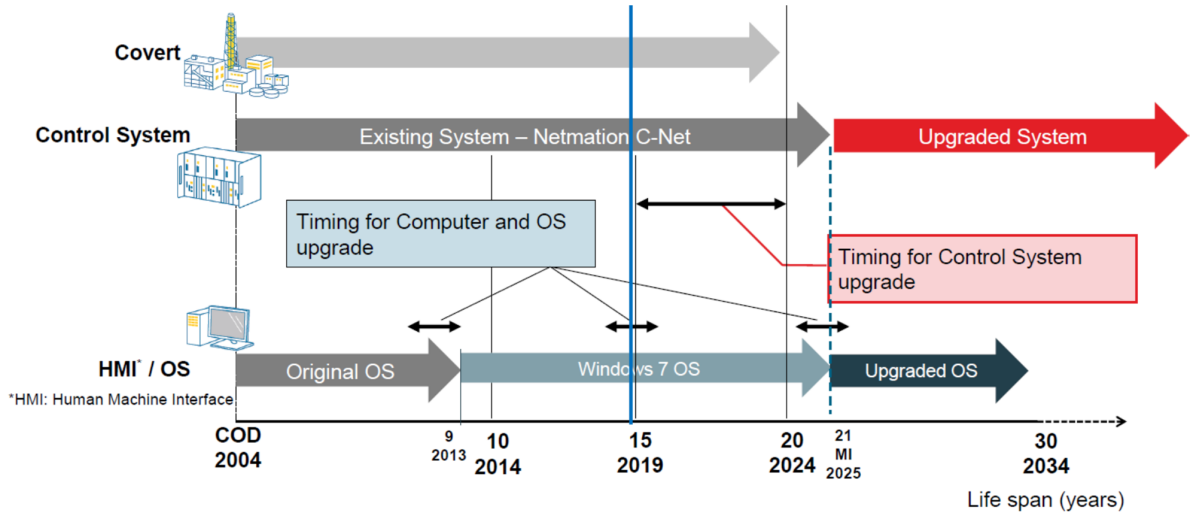

Figure 2 – Covert Netmation Control System Timeline

Operational Challenges

- **Obsolete Operating Systems:** Relies on the now-unsupported Microsoft Windows 7.
- **Outdated Control Architecture:** Utilizes the Allen-Bradley Control-Net based Netmation C-Net architecture, replaced by Mitsubishi with the newer Netmation D-Ring I/O.
- **Processor and I/O Module Obsolescence:** Process controllers and I/O modules operate on old, obsolete architecture, necessitating an upgrade.

Cybersecurity Risks

Security Project Process Risk Overview: This risk was identified and logged by the cybersecurity team prior to the acquisition of the Covert Generation plant. The existing control systems, being outdated, pose high-security risks, which have been formally recognized and assigned a risk ID for continuous tracking. Although not a formal exception, this risk is treated with the same urgency and oversight, with a clear roadmap outlined for remediation.

- **Documenting the Risk:** The risk was formally logged as an existing risk, ensuring it is tracked and managed effectively.
- **High-Risk Integration:** The outdated control systems present significant risks as they are integrated into Consumers Energy's operational framework. This has been acknowledged and tracked to ensure prompt mitigation.
- **Commitment to Remediation:** The control systems at Covert are slated for comprehensive upgrades as part of the integration and risk mitigation strategy, addressing the identified security vulnerabilities.
- **Leadership Oversight:** The Company's cybersecurity leadership has emphasized the need to fix these vulnerabilities, highlighting the importance of the planned upgrades.
- **Critical Infrastructure Protection:**
    - The plant's control systems are integral to the nation's Critical Infrastructure and are subject to NERC Critical Infrastructure Protection (CIP) requirements.
    - Due to the outdated software, the plant is vulnerable to cybersecurity threats. This includes potential exploitation by bad actors and nation states due to unpatched software vulnerabilities.
- **Challenges in System Maintenance:**
    - The plant's reliance on outdated platforms, such as Microsoft Windows 7, and specific applications like the Mitsubishi Netmation, has reached a critical juncture where manufacturer support has ceased.
    - Extended support from Microsoft ended in January 2020. This lack of support inhibits the ability to apply necessary patches and maintain these systems, rendering them susceptible to vulnerabilities. Without these updates, the software may become a target for malicious actors and nation-states, posing a significant risk to our critical infrastructure.

- **Compliance with Corporate Cybersecurity Standards:**
    - The current systems at Covert do not meet the Windows Server Hardening Standard required by Consumers Energy. Servers are required to be on newer builds (Windows Server Enterprise 2016 and 2019).
    - Aging infrastructure limits the effectiveness of crucial cybersecurity measures. Specifically, tools designed for enhancing control network security, such as the Mitsubishi Netmation Protect Pack (NPP), are incompatible with the outdated hardware and software, restricting our capability to perform essential patching and antivirus protections.
- **Limitations on Malware Protection:**
    - The antiquated operating systems currently in use offer limited support for up-to-date malware protection solutions. This limitation not only increases the risk of infection from new strains of malware but also complicates efforts to maintain a secure operational environment, essential for the uninterrupted generation of energy**.**

Alternative Solutions/Alternatives Considered

1. Do Nothing

Continued Use of Outdated Systems:

- **Obsolete Control Systems:** Persisting with the existing Mitsubishi NetMation control systems, which are beyond their operational life cycle and no longer supported by necessary updates or patches.
- **Operational Inefficiency:** These systems are prone to inefficiencies and reliability challenges, impacting overall plant performance and safety.

Policy Violation and Security Implications:

- **Violation of CE Patch Management Policy:** This option results in a direct violation of the CE Enterprise Patch Management Policy, indicating a failure to meet corporate standards for maintaining system security and integrity.
- **NERC CIP Non-compliance:** Retaining outdated systems does not comply with NERC Critical Infrastructure Protection (CIP) requirements, potentially leading to fines up to $1.2 million per day. This represents a significant financial risk and regulatory exposure.
- **Lack of Updates and Patches:** Inability to adhere to regular system patching and update protocols, which are essential for maintaining operational security and efficiency.

Cybersecurity Risks:

- **Heightened Vulnerability:** Using outdated and unpatched systems significantly increases vulnerability to cyber threats. This exposes the plant to potential security breaches that could compromise the integrity of plant operations and sensitive data.
- **Potential for Severe Breaches:** The risk of a cybersecurity event could lead to substantial damage to critical equipment. Repair and replacement in such scenarios would require considerable time and resources, exacerbating operational disruptions and financial burdens.

Operational Impact:

- **System Failures and Trips:** Failures in communication modules linked to remote I/O cabinets could trigger site-wide unit trips, leading to substantial generation and capacity losses, varying by season.
- **Disruption in Control and Monitoring:** Potential disruptions in maintaining consistent operational control and effective system monitoring could deteriorate the plant's overall functionality and response capabilities.

Long-term Consequences of Inaction:

- **Inevitable Need for Future Upgrades:** Doing nothing only postpones necessary upgrades, which will eventually need to be performed under less favorable circumstances and likely at higher costs.

- **Risk of Component Failure:** The aging systems might fail unpredictably, potentially leading to derates or extended downtimes. Control system failures could also precipitate further mechanical component or system failures.
- **Unpredictable Outages and Damage:** It is very challenging to predict when these failures might occur and the extent of potential damage.

Conclusion: Choosing the "Do Nothing" option presents significant cybersecurity risks and operational inefficiencies that could jeopardize the safety, reliability, and regulatory compliance of the Covert Generating Station. This option fails to mitigate any of the identified risks and only delays the inevitable, necessary upgrades, increasing the potential costs and impacts of future failures. This approach is strongly inadvisable as it exposes the facility to increased risks and potential catastrophic failures, which could have severe repercussions for both the plant's operations and the company's reputation.

Option 2: Replace Covert Station Hardware (including I/O modules) and Software to latest architecture - $20,042,000 (internal loaded estimate includes Netmation Care Parts Program)

Under Option 2, we propose an extensive upgrade of the Covert Mitsubishi Turbine Control System to the latest version of Netmation, which includes the replacement of hardware, I/O modules, servers, workstations, network switches, and software to the latest architecture. A significant enhancement to this option is the planned acquisition of the optional Netmation Care Parts Program for an additional investment of $1.5M. This program is specifically designed to support Mitsubishi Power Americas' customers with an efficient, cost-effective solution for managing spare parts over the control system's lifecycle.

Key Benefits of Upgrading to the Latest Netmation System:

- Enhanced System Security and Reliability:
    - Guarantees a secure and reliable control system, foundational for uninterrupted and safe plant operations.
- Compliance with CE Enterprise Standards:
    - Enables adherence to the CE Enterprise Patch Management Policy, requiring regular system updates for maintaining operational security.
    - Ensures timely application of security patches released by Original Equipment Manufacturers (OEM), alongside continuous antivirus and malware protection, crucial for safeguarding system integrity against vulnerabilities and ensuring compliance with enterprise cybersecurity standards.
    - Upgrades to the latest versions of control software and operating systems (including Microsoft, Proxmox, and Linux), accessing up-to-date technological enhancements.
- D-Ring I/O System Advantages:
    - Implements redundant I/O adapters, enhancing system resilience against hardware failures.
    - Introduces network broken point detection, improved diagnostics, easier log collection, and consolidated module functionality, reducing the number of spare parts required.
- Remote Combustion Tuning:
    - Enables remote adjustments to the combustion system, accommodating seasonal turbine performance optimizations.

- Cybersecurity Lifecycle Management Program with Netmation Protect Pack integration:

  The upgraded control system at the Covert plant, including the introduction of the Netmation Protect Pack (NPP), significantly enhances cybersecurity management across several domains:

  - **Regular System Patching and Updates**: NPP ensures that the latest security patches and system updates are applied, aligning with CE Enterprise Patch Management Policy for maintaining operational security. This routine patching is crucial, especially for systems under constant evolution in cybersecurity threats.
  - **Advanced Threat Management**: NPP integrates comprehensive cybersecurity solutions including threat and risk management, which are vital for protecting the control systems against unauthorized access, malware, and ransomware attacks.
  - **Application Control and System Health Monitoring**: With NPP, the plant can manage applications more securely and monitor system health effectively, ensuring that any potential security risks are identified and mitigated promptly.
  - **Compliance with Regulatory Standards**: The NPP platform supports compliance with NERC/FERC CIP reliability standards, crucial for plants part of the nation's critical infrastructure. This compliance is enforced through regular reports and audits, ensuring that the plant meets all necessary cybersecurity benchmarks.
  - **Backup and Recovery Protocols**: The program includes robust backup and recovery systems, which are essential for restoring operations quickly and securely in the event of a cyber incident.
  - **Vulnerability Scanning and Assessment**: Regular scans are conducted to identify and address vulnerabilities, with assessments ensuring that the control systems are fortified against potential breaches.
  - **Periodic Site Reviews and Assessments**: Alongside the continuous monitoring and updates, periodic site visits are conducted to review the system's security posture and implement necessary improvements based on the latest cybersecurity trends and findings.

Benefits of Including the Netmation Care Parts Program:

While the core of Option 2 focuses on modernizing the Covert station's control systems, the Netmation Care Parts Program offers additional, valuable benefits:

- Strategic Parts Management: The program provides a comprehensive solution for managing spare parts throughout the system's lifespan, ensuring that critical spares are readily available on-site and non-critical spares are secured at a Mitsubishi warehouse, thus minimizing potential downtime.
- Alignment with LTSA and Plant EOL: By securing spare parts for the Netmation D-Ring Control Systems for all three blocks, the program supports the units up to the expected end of the Long-Term Service Agreement (LTSA) in 2038, offering a strategic alignment with future operational needs.

- Reduction in Variable Costs: This strategic financial approach not only aligns with the plant's LTSA but also serves as an effective method to support the units while substantially reducing costs. By transitioning spare parts expenses from variable, often unforeseen costs to a planned approach, the program provides a more predictable and manageable cost structure.

Option 3: Limited Upgrade Excluding C-Net I/O Transition – $5M initial cost with a minimum cost of $20,042,000 within 5 years for inevitable full upgrade.

Option 3 proposes a targeted upgrade path for the Covert Mitsubishi Turbine Control System, focusing on updating servers, workstations, network switches, and the control system software. This approach notably omits the upgrade of the existing C-Net I/O modules to the newer D-Ring I/O architecture, aiming to streamline the upgrade process by minimizing hardware alterations and the associated labor costs.

Key Aspects of Option 3:

- Selective Modernization Efforts:
    - Concentrates on upgrading the control system's computational and networking backbone, including servers and switches, alongside software enhancements.
    - Retains the current C-Net I/O modules, bypassing the shift towards the more modern D-Ring I/O system architecture.

Considerations and Limitations:

While this strategy might appear to offer a straightforward path to modernization with potentially lower initial costs, it's essential to acknowledge the broader implications and the benefits that will be missed:

- Foregoing Enhanced Reliability and Diagnostics:
    - By not adopting the D-Ring I/O system, the plant misses out on significant reliability improvements, including redundant I/O adapters and advanced diagnostics, that could mitigate the risk of system failures and facilitate faster troubleshooting.
    - The architecture is significantly past the recommended replacement interval. Commissioned in 2004, all (3) systems will be 22-years old in 2026, which is 7-years beyond the 15-year replacement recommendation. The reliability of the system will be in question and replacement parts become completely obsolete as the system ages further.
- Continued Vulnerability to Network Failures:
    - The absence of network broken point detection capabilities means that the system remains more susceptible to network issues, potentially affecting operational stability and increasing downtime.
    - The controllers that operate the plant equipment would still be vulnerable to cyber-attacks.
    - Vulnerabilities and reliability of the old controllers would be decreasing as they age.

- Unrealized Operational Efficiencies:
    - The consolidated module functionality and reduced spare parts requirements offered by the D-Ring architecture represent unclaimed efficiencies that could streamline maintenance operations and reduce long-term costs.
    - This option does not replace any of the thousands of I/O modules that are obsolete with the old C-Net architecture.
    - The following benefits of the D-Ring I/O would not be realized: redundant I/O adapters for failure-resistant I/O network, network broken point detection, consolidated module functionality for a reduction of required spares, Improved I/O modules diagnostics and easier log collection.
- Stagnation in Technological Advancement:
    - Electing to bypass the D-Ring I/O upgrade will limit the system's future scalability and adaptability to emerging technologies.

Option 3 offers a constrained upgrade focusing on immediate needs while leaving existing I/O infrastructure untouched. This choice might initially seem prudent from a cost perspective; however, the initial cost of $5M would only provide a short-term solution that would eventually still require the full I/O and controller replacement as recommended. As the inevitable upgrade is delayed, the generating plant gets nearer its end of life and less time remains to maximize the benefit of the investment.

Recommended Alternative: # 2. Replace Covert Station Hardware (including I/O modules) and Software to latest architecture - $20,042,000 (internal estimate includes Netmation Care Parts Program).

The decision to pursue Option 2, the comprehensive replacement of all hardware and software to the latest architecture at the Covert Generating Station, is underpinned by detailed asset reviews, cybersecurity assessments, and recommendations from Mitsubishi. This option promises enhanced reliability, security, and economic benefits, crucial for meeting future operational and security demands.

Key Findings and Assessments:

- **Asset Review Findings:**
    - Aging Infrastructure: PCs running Windows 7 are over 12 years old, facing imminent drive failures. Control processors and I/O modules are over 20 years old, significantly beyond their effective operational lifespan.
- **Cybersecurity Assessment Results:**
    - Security Vulnerabilities: Current system monitoring and access control are limited to non-existent, leaving critical infrastructure highly vulnerable to unauthorized access and malicious activity.
    - Corporate Mandate: The cybersecurity leadership has logged the issue as an existing risk with an assigned risk ID, highlighting the urgent need for system upgrades to mitigate potential security risks. This tracking mechanism ensures continuous oversight and emphasizes the necessity for immediate remediation efforts to address the identified vulnerabilities.
- **Manufacturer's Recommendation:**
    - Mitsubishi's Urgency: Mitsubishi has recommended that a component and architecture replacement should have occurred by 2019 to ensure system integrity and security up to its expected end of life.
- **Economic and Operational Efficiency:**
    - Long-Term Cost Savings: Although initially more capital-intensive, this option prevents the frequent and costly updates required if older systems were maintained. By investing in a comprehensive overhaul now, the station avoids the escalated costs associated with piecemeal upgrades or emergency repairs in the future.
    - Improved System Longevity and Reliability: The upgrade extends the operational lifespan of the control systems, ensuring they remain functional and effective until at least 2038, as per Mitsubishi's guidelines. This not only enhances operational reliability but also provides a clear, long-term upgrade path through virtualized systems.

Scope of work

Control System Requirements:

1. **Independent Control Systems:**
    - Each generating unit (Block) will be equipped with independent control systems featuring secure network interfaces to ensure isolated operations and enhanced security.
2. **Virtualization and Server Infrastructure:**
    - Implementation of a virtualized Netmation server-based platform for all Human Machine Interfaces (HMIs) and Netmation servers.
    - Utilization of Proxmox Virtual Environment on multiple host rack servers to provide high-availability clustering.
    - Network Attached Storage (NAS) will be used for robust data storage and integrity.
3. **Networking and Power Supply:**
    - Installation of redundant 1Gbps and 10Gbps managed switches and firewalls to ensure network resilience and security.
    - Uninterruptible Power Supplies (UPS) will be installed for all server rack components and PCs to provide continuous power and prevent data loss during power disruptions.
4. **Cybersecurity Enhancements:**
    - Deployment of the Netmation Protect Pack (NPP) to offer integrated threat management, risk management, and application control.
    - Comprehensive cybersecurity tools will be implemented, including disaster recovery, logging, Active Directory authentication, and regular system patching and updates to comply with NERC CIP and Consumers Energy standards.
5. **System Software and Hardware Upgrades:**
    - The project will include the latest approved operating systems for virtualized servers and HMIs, along with application software and components.
    - Monthly software patching and threat monitoring as part of Mitsubishi's Cybersecurity Lifecycle Management Program.
    - Upgrade of the Netmation D-Ring (I/O) System, including the replacement of C-Net I/O hardware modules with the latest D-Ring modules and processors on all Gas Turbine Control (GTC) and Steam Turbine Control (STC) systems.

6. **Remote Management and Tuning:**
    - Implementation of remote tuning capabilities for combustion tuning, compliant with NERC CIP, through a secure and controlled connection, facilitating quicker and cost-effective tuning.
7. **Spare Parts Management:**
    - Establishment of the Netmation Care Parts Program to ensure availability of critical spare parts for the Netmation D-Ring Control System on-site and non-critical spares stored at a Mitsubishi warehouse, supporting all units until the end of the current LTSA in 2038.

Funding and Timing

- A planned outage is required for this project.
- Desired implementation year:
    - First year spend: 2024
    - Implementation year: 2026

System Engineer

- System Engineer: Kevin A. Ortner

Conceptual Estimate

Year	Loaded Cost	Description
2024	$3,776,000	Engineering and initial contract award to Mitsubishi
2025	$4,922,000	Engineering
2026	$10,304,000	Spring and fall Outage installations of all Servers and I/O and controllers
2027	$1,040,000	Acceptance and closeout

Total Cost: $ 20,042,000

Asset Strategy Approval Comments

Asset Strategy approves this project due to its critical alignment with essential cybersecurity requirements and the imperative to sustain operational reliability at the Covert Station. This strategic upgrade not only ensures compliance with the CE Enterprise Patch Management Policy but also integrates the latest technological advancements, thereby fortifying the long-term integrity and efficiency of the plant's operations.

This project at the Covert Generating Station **is** recognized in the 2023 electric rate case, not as a standalone item but within the broader category of non-LTSA (Long Term Service Agreement) projects. This categorization reflects the strategic allocation of funds for various essential undertakings at Covert, following its recent acquisition.

The allocated budget under work item 1218, titled "Covert -Non LTSA Capital - Extras not included in contract," encompasses this and other similar projects. The figures covered under this line item are as follows:

Amount set for Bridge year: $ 3,943,000

Amount set for test period: $ 5,510,000

Covert station DCS Evergreen Upgrade

Date: 3/2/2024

Prepared by: Paul Ohep

Figure 1. Covert Generating station

Executive Summary

The Covert gas generation plant, operational since 2004, faces significant challenges with its Emerson Ovation Distributed Control System (DCS). The system's obsolescence, cybersecurity risks, and operational inefficiencies necessitate an urgent upgrade to the latest version to enhance reliability, security, and compliance with regulatory standards.

Problem Overview:

1. **System Obsolescence and Lack of Support:** The existing DCS (version 3.5.1) is outdated, with Emerson and Microsoft no longer providing support. The software and operating systems, including Windows 7 and Server 2008R2, have reached end-of-life, with no extended support available.
2. **Cybersecurity Risks and Compliance Challenges:** The plant's control systems are subject to NERC Critical Infrastructure Protection (CIP) requirements. Continued use of outdated software exposes the plant to heightened cybersecurity threats and potential fines up to $1.2 million per day for non-compliance.
3. **Operational Risks and Inefficiencies:** Failures in communication modules to remote I/O cabinets have led to generating unit trips, causing significant generation and capacity losses. The main controller drop is overburdened, increasing the risk of simultaneous unit trips, necessitating a system restructuring.

Alternatives Considered:

1. **Do Nothing:** Persisting with the current system risks violating CE Enterprise Patch Management Policy, failing to meet corporate standards, and incurring substantial fines for non-compliance with NERC CIP requirements.
2. **Replace DCS with Latest Version:** A proactive upgrade at an estimated cost of $3,540,000 enhances system security, ensures compliance with CE Enterprise standards, and accesses the latest technological innovations for improved operation.

Recommended Solution: Upgrading the DCS to the latest version is the chosen approach, driven by the need for enhanced security, compliance with enterprise standards, and technological advancement. The upgrade includes:

The upgrade of Covert Station's DCS to the latest version represents a critical step towards maintaining the plant's operational integrity, adhering to cybersecurity standards, and ensuring regulatory compliance. This initiative is not only a response to current challenges but also a proactive measure to future-proof the plant's control systems.

Financial Summary

Funding Type:	Capital
Estimated Total Cost:	$3,540,000

Proposed Start Implementation Year and Duration

2024-2026

Problem Description

The Covert gas generation plant, in operation since 2004, is currently facing significant challenges with its control system, the Emerson Ovation Distributed Control System (DCS). This system, essential for the plant's operation, is now outdated and poses several risks and inefficiencies.

1. **System Obsolescence and Lack of Support:**
    - The plant's Emerson Ovation DCS, at version 3.5.1, is outdated with Emerson and Microsoft is no longer providing support.
    - Critical software, including Emerson Ovation version 3.5 and the Windows operating systems (Windows 7 and Windows Server 2008R2), have reached their end-of-life, with extended support from Microsoft having ended in January 2020.
2. **Cybersecurity Risks and Compliance Challenges:**
    - The plant’s control systems are integral to the nation’s Critical Infrastructure and are subject to NERC Critical Infrastructure Protection (CIP) requirements.
    - Due to the outdated software, the plant is vulnerable to cybersecurity threats. This includes potential exploitation by bad actors and nation states due to unpatched software vulnerabilities.
    - The cybersecurity tools currently in use, such as the Power & Water Cybersecurity Suite (PWCS), are nearing the end of their support and are incompatible with newer versions of the Ovation system.
3. **Balance of Plant (BOP) Control Inefficiencies:**
    - There have been incidents of failures in communication modules to remote I/O cabinets, leading to generating units going offline.
    - The power supplies in the Ovation cabinets, having exceeded their manufacturer suggested lifespan, need urgent replacement.
4. **Operational Risks and Inefficiencies:**
    - The main controller drop, responsible for equipment control across all three generating units, is overburdened and has been subjected to additional equipment and data link controls over the years.
    - This overextension has led to increased risk of simultaneous unit trips and necessitates a restructuring of the control system to ensure operational efficiency and safety.
    - The current system configuration requires site-wide outages for certain upgrades, leading to significant operational risks and inefficiencies.

The Covert Station's control system is in urgent need of an upgrade. The current Emerson Ovation DCS system, being outdated, poses significant risks in terms of cybersecurity, operational efficiency, and compliance with regulatory standards. An upgrade to the latest

Emerson DCS Evergreen system is crucial to address these challenges, enhance the plant's operational reliability, and ensure compliance with critical infrastructure protection standards.

Alternative Solutions/Alternatives Considered

1. Do Nothing

   Choosing not to upgrade the Distributed Control System (DCS) at Covert Station involves persisting with the current, outdated systems. This approach, however, leads to several critical issues:

   - **Continued Use of Outdated Systems:**
     - Retaining the existing retired DCS operating systems, which are beyond their optimal life cycle and no longer receive necessary updates or patches.
   - **Policy Violation and Security Implications:**
     - This course of action results in a direct violation of the CE Enterprise Patch Management Policy, failing to meet established corporate standards for system maintenance.
     - Non-compliance of NERC Critical Infrastructure Protection (CIP) requirements can lead to fines of up to $1.2 million per day.
     - Inability to adhere to regular system patching and update protocols, essential for operational security and efficiency.
   - **Cybersecurity Risks:**
     - Significantly heightened vulnerability to cyber threats due to the use of outdated and unpatched systems.
     - Increased risk of security breaches, which can compromise the integrity of plant operations and sensitive data.
   - **Operational Impact:**
     - Likely occurrence of system inefficiencies and reliability challenges.
     - Failures in communication modules linked to remote I/O cabinets can trigger site-wide unit trips, leading to considerable generation and capacity losses. The extent of these losses varies depending on the time of year.
     - Potential disruption in maintaining consistent operational control and effective system monitoring.

2. Replace Covert Station Ovation DCS with the latest version available at the time of the project - $3,540,000 (internal estimate)

Upgrading the Distributed Control System (DCS) at Covert Station to the latest version represents a proactive approach to maintaining system security and operational efficiency. Key aspects of this option include:

- **Enhanced Patching and Security:**
  - Capability to continually patch computer operating systems, ensuring the DCS remains secure and reliable.
  - Alignment with the CE Enterprise Patch Management Policy for regular system updates.

- **Up-to-Date Control Software and Operating Systems:**
  - Introduction of the latest versions of Emerson Ovation control software, Microsoft, and VMware operating systems.
  - Ensures reliable operation and control of the generating units with the most current software versions.
- **Access to Latest Features and Enhancements:**
  - Eliminate Single Point Vulnerability to cause multi-unit trips by partitioning of I/O to other drops.
  - Availability of the latest feature enhancements for improved operation of the unit.
  - Ability to apply the most recent patches provided by cybersecurity PWCS applications.
- **Compliance with Enterprise Standards:**
  - Meeting the requirements of the CE Enterprise Patch Management Policy for annual patching of operating systems.
  - Running antivirus and malware prevention software on all systems as a standard security protocol.
  - Prompt application of new security patches released by OEMs for software applications.

Recommended Alternative: # 2. Replace Covert Ovation DCS with the latest version available at the time of the project - $3,540,000.

The decision to upgrade Covert Station Distributed Control System (DCS) to the latest version, at an internal estimated cost of $3,540,000, is driven by several compelling reasons:

- **Enhanced System Security and Reliability:** The upgrade ensures that the DCS remains patchable, aligning with evolving cybersecurity measures. This is vital for maintaining a secure and reliable control system in the face of increasing cyber threats.
- **Compliance with CE Enterprise Standards:** Regular patching and updating of the system as per the CE Enterprise Patch Management Policy are mandatory for operational security. This upgrade facilitates annual patching of operating systems, along with consistent running of antivirus and malware prevention software.
- **Ensuring Compliance and Avoiding Financial Risks:** Adherence to NERC Critical Infrastructure Protection (CIP) standards is crucial, as the plant's control systems are integral to the nation's Critical Infrastructure. Non-compliance risks not only operational integrity but also incurs substantial fines, potentially up to $1.2 million per day.
- **Technological Advancement:** By upgrading to the latest Emerson Ovation control software and operating systems (Microsoft and VMware), the units gain access to the latest technological innovations. This ensures efficient and reliable operation and control of the generating units.
- **Feature Enhancements and OEM Support:** The upgrade enables the incorporation of the latest feature enhancements, improving operational capabilities. It also ensures that the station can apply the latest security patches released by Original Equipment Manufacturers (OEMs), maintaining the system's integrity.

Option 2 aligns with the necessary cybersecurity and operational standards. This upgrade is a strategic investment in the plant's future, ensuring its compliance, security, and operational excellence.

Scope of work

1. **Software and Operating System Upgrades:**
    - Upgrade all Ovation software to the latest version.
    - Update all Operating Systems to the latest version supported by Ovation.
2. **Hardware and Infrastructure Replacement:**
    - Install the latest generation of Ovation power supplies.
    - Replace all network switches, routers, firewalls, and media converters.
    - Upgrade fiber optic cabling to support the new system and Remote Node Interface.
    - Replace all Remote Node Controllers (RNC and MAU) with Remote Node Interface (RNI) architecture for remote I/O cabinets.
3. **Control System Restructuring:**
    - Add two new controller drops to redistribute the logic and control from the existing drop1 controller.
4. **Cybersecurity Enhancements:**
    - Upgrade PWCS cybersecurity tools, incorporating new hardware and software solutions.
5. **Virtualization and Server Upgrades:**
    - Transition to an Ovation Virtualized system, including VMware hosts, Storage Area Network (SAN), network switches, Thin Clients, Network-Attached Storage (NAS), and all necessary components and software.
6. **Communication System Upgrades:**
    - Replace Mitsubishi gateway devices and software for data link communication with the latest secure protocols.

Funding and Timing

- A planned outage is required for this project.
- Desired implementation year: 2024

System Engineer

- System Engineer: Kevin A. Ortner

Conceptual Estimate

Year	Loaded Cost	Description
2024	$551,500	Contract award, engineering, and project management support.
2025	$2,988,500	Emerson DCS Evergreen replacement of existing application software and operating systems and equipment.

Total Cost: $ 3,540,000

Asset Strategy Approval Comments

Asset Strategy approves this project because of its alignment with the essential cybersecurity requirements and the need to maintain operational reliability at the Covert Station. This strategic upgrade ensures compliance with the CE Enterprise Patch Management Policy and leverages the latest technological advancements, thus safeguarding the long-term integrity and efficiency of the plant's operations.

This project at the Covert Generating Station **is** recognized in the 2023 electric rate case, not as a standalone item but within the broader category of non-LTSA (Long Term Service Agreement) projects. This categorization reflects the strategic allocation of funds for various essential undertakings at Covert, following its recent acquisition.

The allocated budget under work item 1218, titled “Covert -Non LTSA Capital - Extras not included in contract,” encompasses this and other similar projects. The figures covered under this line item are as follows:

Amount set for Bridge year: $ 3,943,000

Amount set for test period: $ 5,510,000

Concept Approval Internal Report

Investment Code	Report Start Year	Number of Years	Currency Scale
GEN002894	**2026**	**2**	**Literal**

Investment Name	Scenario
CGS - Units 1,2,3 NERC Relay Replacements and Test Switch Installation	**Draft**

Value Function	**Consumers Energy Value Function**

Each unit has multiple digital protection relays to ensure protection to the generation equipment (Generators/Exciters/Transformers) from local faults as well as to ensure protection from grid disturbances that could damage our valuable equipment. The relays within the scope of this project have manufacture/installation dates very close to 2002. At Covert – there are two specific brands of relays in scope for this work – Beckwith and Schweitzer relays. In addition to changing the relays from 2002 vintage to today's models, this project will install relay test and cutout switches to be consistent with industry best practices and to ensure safe and reliable testing and maintenance. The original relays at Covert were not installed with the necessary test and cutout switches - which requires that the unit be offline for maintenance and replacement and creates a greater potential for human performance errors that can lead to forced shutdowns.

Investment Type	Generation	Planning Portfolio	Covert
Facility	Covert / Covert		
Executive Summary	This project proposes the replacement of aging digital protection relays and installation of relay test and cutout switches across Units 1, 2, and 3 at Covert Generating Station. These relays are critical for protecting generation equipment (generators, exciters, transformers) from local faults and grid disturbances. The existing relays, installed around 2002, are approaching or have reached the end of their recommended 25-year service life, and failures have already begun to occur. Objectives Avoid human performance errors leading to forced outages and reduce the need for offline maintenance. Scope & Schedule Unit 3: Spring 2026 major outage. Unit 1: Fall 2026 major outage; most complex and critical. Unit 2: Split between Spring and Fall outages in 2027 due to limited outage duration. Justification & Risk Assessment Service Life: Relays will be at 24–25 years of service at time of replacement, aligning with System Protection recommendations. Observed Failures: Unit 3 experienced a relay failure in December 2024; currently operating without redundant protection in one zone. Forced Outage Risk: If backup relay fails before scheduled outage, a 14-day forced outage would be required. Assumed probability of this risk: 5%. Estimated capacity revenue losses: $1,374,765 (based on MISO rules and 75% of CONE value). Industry Standards: Running relays to failure is not acceptable practice and exposes the company to scrutiny and reliability risks. Test Switches: Without switches: increased risk of human error during maintenance. With switches: risk probability reduced from 5% to 1%. Avoids need to unwire/rewire relays during maintenance. Estimated annual O&M cost avoidance: $5,000. Recommended Alternative: Replace all NERC protection relays and install test/cutout switches to ensure safe, efficient, and reliable operation. Other Alternative (Not Chosen): Replace relays only, without installing test switches. Estimated cost savings: $150,000 per unit. Not recommended due to increased maintenance complexity and risk exposure.		
Last Approver		Approval Date	

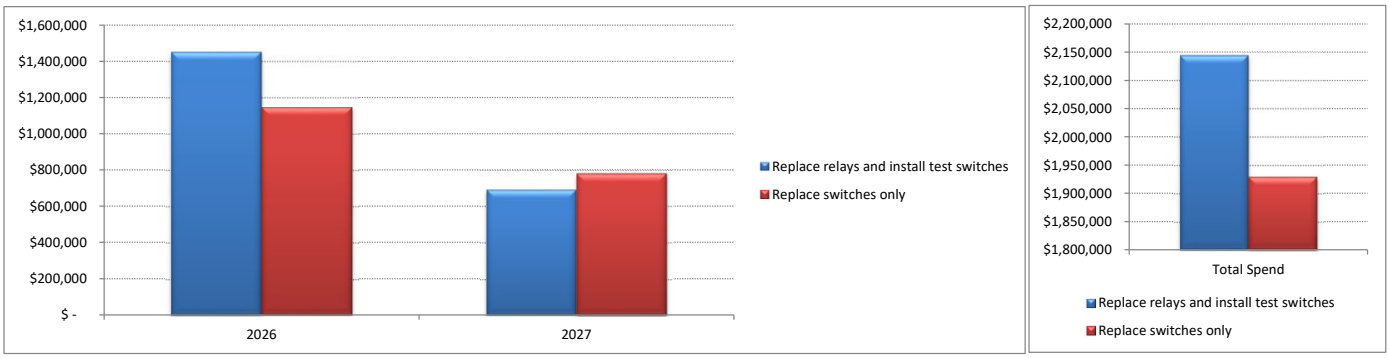
Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 3
	Rate Case Mapping	Gas Generation
	EPM Managed	Yes
	Outage Type	Unit - Plant
	Scope	•Unit 3 will be done in Spring 2026 Major Outage; Unit must be out of service for this work to be performed. It is best to do these jobs (especially the first ones) in MAJOR outage windows because of the complexity of this project. •Unit 1 will be done in Fall 2026 Major Outage; for same reasons as Unit 3. Unit 1 will be the most complex and is the most crucial to being funded in 2026. •Unit 2 will be done in two parts – spring and fall outages of 2027 because there is not a long enough outage for all of the work, we will split into two parts. •It is important that these projects be scheduled soon because the relays are at end of life and at least one on Unit 3 has showed indications of failing. General Scope: For each of Covert's Generating Units, replace all relays (primary & backup) associated with Gas Turbine Generator & Excitation Protection, Steam Turbine Generator & Excitation Protection, Generator Step-up Transformer Protection, Station Auxiliary Transformer Protection, & GTG & STG Transformer Winding Protection Relays (single relay for each). With each of the relay replacements, provide relay cutout switches, sufficient test switches, and a sufficient time signal to synchronize all relay time-stamps to a new GPS timeclock. This project will procure all relays and time clocks for each unit as well as all relevant hardware and cabinetry (or new panels as required) to create the space required to install the new gear (original equipment does not have workable relay cutout switches and test switches or sufficient space within or on the existing panels/cabinets to simply do a "remove/replace" project).
	Objectives	This project is needed to preclude unnecessary risk associated with possible relay failures as our relays are at end of life. Running to failure is not an option for relay protection equipment because of the extremely high costs of equipment failures that could result if relay protection schemes failed to operate as designed. In late 2024, Covert experienced its first indication of a relay failure on unit 3, and is operating at this time with no redundant protection in this specific zone. The failed relay is original from 2002 and more relay failures can be expected as time goes on. With this as an example – if Covert were to have a failure of the remaining protection scheme in this zone – a forced outage would be required to prevent an event – and it is expected that the turn-around time for sourcing, testing, installation, and commissioning of relays like this would take ~ 2 weeks if all went well. Relay manufacturers and Consumers Energy's High Voltage Distribution group use 25 years as recommended service life for these types of devices. Project Benefits All of the NERC protection relays will be replaced in accordance with industry best practices and relay test & cutout switches will be installed to make testing and maintenance safer and more consistent to ensure reliable relay and unit performance. If a relay failure were to occur in the future, relay replacement could be done online if deemed necessary.

Concept Approval Internal Report

Investment Code	Report Start Year	Number of Years	Currency Scale
GEN002894	**2026**	**2**	**Literal**

Investment Name	Scenario
CGS - Units 1,2,3 NERC Relay Replacements and Test Switch Installation	**Draft**



Value Function	**Consumers Energy Value Function**

	Planner Recommended Alternative	Replace NERC relays and install test switches. -Beckwith OEM for many of the relays in scope recommends replacement at 1.5x the relay warranty period (or 15 years). Beckwith acknowledges that they have many relays in service at 20 years. Within Consumers Energy's HVD relay replacement program – relays are replaced at 25 years – which is where we are establishing the need for this action. -Schweitzer Engineering Laboratories (SEL) is the OEM for the balance of the relays in service at Covert – expects their relays to have a minimum service life of 20 years. Within Consumers Energy's HVD relay replacement program – relays are replaced at 25 years. Other alternative (not chosen) For each of three units, replace only the relays and do not install test/cutout switches contrary to industry best practices – cost savings of ~$150K/unit estimated. This option is not recommended because to perform relay maintenance at Covert requires the relays to be unwired and rewired – each time maintenance is performed and this is not a good way of doing maintenance and is not in keeping with industry best practices.
	Assumptions	System Protection recommends relay replacements at 25 years of service. These relays were first put in service ~ 2002. The project schedule proposed would have Units 3 & 1 at 24 years of service and Unit 2 at 25 years of service at replacement. We are starting to observe relay failures (Unit 3). Loss of protection would require an unacceptable outage and loss of generation that would easily exceed this project cost in energy value replacement costs. (Example: if Unit 3 experienced failure of the redundant protection device, it is estimated that an outage of ~ 14 days would be required to procure, test, install, & commission – new relays to restart the unit.) . Running these relays / components to failure is not industry standard. Risks associated with running protective relays to failure – compromising either protection or experiencing an uncoordinated protective function or unit trip from a faulty relay is simply not industry best practice and would call unacceptable scrutiny upon CE and our practices. These relays are being replaced at the best time with respect to length of service and exposure to unnecessary failures. Unit 3's Backup Excitation Protection Relay failed in service in December of 2024 after this project was in conceptual form. These devices do not fail frequently prior to end of life. Assume that there is a single relay that has failed (as in the case of Unit3) – and it's backup relay fails before we have an outage of opportunity to repair or replace the first failed relay – a forced outage is required. (This assumes that the relays fail passively and do not initiate a unit trip.) Assume a 5% chance of realizing this risk will be assumed based on equipment redundancy. Risk (HIGH) - relatively low probability * HIGH consequences if we continued to run with no protection and had an event that relays did not protect for because we did not come offline to fix. Potential capacity losses from a 14 day forced outage have been calculated using a calculator provided by capacity forecast group to be $1,374,765. This includes a three year impact in accordance with MISO rules. Assume a CONE value of $130,930. a 75% of CONE value figure was used for calculations as is customary. Option without test switches does not fully mitigate lost generation risk as it creates opportunities for human performance errors during maintenance. Installation of these switches has become an industry standard and a standard companywide as well. Assume that probability was reduced from 5% to 1%. By installing test switches, maintenance is avoided since there would be no need to unwire and rewire the relays every time maintenance is performed. Assume annual O&M cost avoidance of $5k.
Alternative Details	Replace relays and install test switches	Replace relays and install test switches
	Replace switches only	Replace switches only.

Investment Name	Scenario
CGS - U13 Circ Water pump replacements	**Draft**

Value Function	**Consumers Energy Value Function**

Investment Type	Generation	Planning Portfolio	Covert
Facility	Covert / Covert		

Executive Summary

resolve the vibration issue may be to purchase this pump for replacement on the remaining units plus a spare (total of 5 new pumps). The pumps have a 62-week lead time and require progress payments. One pump will be purchased in 2025 to try in another location before executing this project.
Objectives:
Mitigate the risk of shutdown and/or derate by replacing the Circ water pump and motor. This particular pump is a large vertical turbine pump that runs continuously and is crucial to plant operation. The typical service life for a pump/motor of this type is 10 to 15 years, but the current pump has been operating for over 22 years. In 2023, a similar pump (2A) failed a shaft, resulting in a unit trip and forced outage on U2.

Planner Recommended Alternative:
Replace the Pump and Motor with rebuilt units (like new with warranty). The current motor in stock is new due to the 2B Motor being damaged beyond repair. A rebuilt pump is returned to like-new status at about 25% of the cost of a new one, with lead times of less than 12 weeks. Purchase one pump in 2025 to replace in Spring 2027. Once installed and proven, execute this project to purchase five additional pumps for replacing other units.
Other Alternative Considered:
Replace Pump and Motor with new components. The cost would be approximately $1.25 million for a new replacement, with a 56-week lead time as a new pump of this size would need to be built by the OEM.

Model Assumptions:
Calculation data supplied by the capacity forecast department:
$196,395 for a 2-day forced outage. $248,078 for a 2-week 60MW derate. CONE value: $130,930.

The 2A failure in October 2023 (pump/motor were 22 years in service) caused a forced outage that lasted 15 days. The unit trip caused a tube failure that extended the outage, so the full extent was not attributed to the pump.

The pumps were designed to be 50% capacity each. However, in the winter months, a single pump can operate and maintain adequate condenser cooling. During the summer months, a single pump results in approximately a 50 to 60 MW derate. Depending on the failure, it may result in a unit trip that has the potential to cause additional unit damage, as seen on unit 2 in October 2023.

Based on best engineering judgment with these types of pumps and plant experience with recent failures, the risk of failure is extremely high. Given the recent failure history of multiple pumps at the Covert site, we will assume a near-certain probability of failure.

Derate Assumptions:
60MW derate for 12 weeks. The probability of occurring is almost certain based on recent failure history for similar pumps.

Investment Overview

Project Details		
	Environmental Justice Area	No
	Estimate Class	Class 2
	Rate Case Mapping	Gas Generation
	EPM Managed	No
	Outage Type	Unit - Plant
	Scope	Replace pump and motor. Refurbish existing motor and keep as critical spare.
	Objectives	Mitigate risk of forced shutdown and/or derate by replacing Circ water pump and motor. This particular pump is a large vertical turbine pump that runs continuously and is important to plant operation. Typical service life for a pump/motor of this type is 10 to 15 years. Pump has been operating for > 22 years. in 2023 a similar pump in age and type failed a shaft (2A) resulting in unit trip and forced outage on U2. Plant engineering has contracted with HydroAire since Spring 2024 to determine root cause of high vibrations on current ITT pump installations and have not reached any conclusions that would allow for reliable modifications to existing assets. The purchase of a new asset once completely proven in the field is the next best option.
	Planner Recommended Alternative	Replace Pump and Motor with Rebuilt units (like new with warranty). The current motor in stock is actually new due to the fact 2B Motor was damaged beyond repair. A rebuilt pump is returned to like new status at a cost of about 25% new with lead times less than 12 weeks. Purchase 1 pump in 2025 (currently have budget) to replace in Spring of 2027. Once installed and proven execute this project to purchase 5 additional pumps for replacing other units. 2025: downpayment for 1 pump 150k 2026: Replace 3A pump and pay for the rest of the ordered pump - $1.1M 2027: Order 5 pumps, install 1 pump - $1.25M 2028: Receive 5 pumps, install 3 pumps - $3.25M 2029: Install final pump, stock 1 spare pump, 1 spare motor - $500k alternative option: Replace Pump and Motor with New. Cost would be ~ $1.25 million for new replacement and result in a 56 week lead time as a new pump this size would need to be built by OEM. We have a spare on site that will be installed in 2A October 2025. Then we will have at least a 36 week lead time to get our spare back because the impeller failed and that item is very long lead. So we will have Significant risk going into 2026. The pumps were designed to be 50% capacity each, however in the winter months a single pump can operate and maintain adequate condenser cooling. During the summer months a single pump result in approximately 50 to 60 MW derate (Single pump operation will result in 50 to 60 MW derate between April 1st and January 1st.). Depending on the failure it may result in a unit trip that has the potential to cause additional unit damage as seen on unit 2 in October 2023.

Value Function	**Consumers Energy Value Function**

Covert - HEPS/FAC/DAST Inspections (Capital)

Investment Type	Generation	Planning Portfolio	Covert
Facility	Covert / Covert		

Executive Summary

This project aims to bring the Covert site into compliance with existing corporate governance on G-A-313, G-A-314, and G-A-315 programs. Compliance with these programs ensures the safe operation of the site and provides outage scheduling flexibility by transitioning from a potential 12-month operating certificate to 3-year operating certificates.
Scope:
The project involves performing HEPS/FAC/DAST inspections to ensure compliance with G-A-313, G-A-314, and G-A-315 programs.

Objectives:
The primary objective is to bring the site into compliance with the specified programs and enable the achievement 3-year operating certificates.The project is essential to maintain the ability to implement 3-year operating certificates. Failure to perform the required inspections would limit the unit to a 12-month operating certificate, necessitating a full inspection before the unit can be certified to operate.

Model Assumptions:
The project assumes the loss of an extended operating license interval, requiring approximately a 10-day outage each year along with the associated costs of performing required testing and certifications. The project is expected to result in cost savings of $2.5 million in O&M for annual boiler certificate inspections, assuming $50,000 for safety valve testing, drum inspections, etc.
Based on recent NDE results, if nothing is done, there is reasonable assurance that a pipe failure a pipe failure will occur with a 5% probability. It will be assumed that it will take 60 days of forced outage to recover from this scenario. This assumption is based on recent outage data.

Benefits:
The project allows for outage scheduling flexibility by moving away from a 12-month operating certificate, thereby reducing the frequency and cost of inspections and ensuring the continued safe operation of the site.

CGS – Replace Bleach Storage Tank, Dosing System, and Building	**Draft**

Value Function	**Consumers Energy Value Function**

Covert Generating station has utilized the sodium hypochlorite system since the system was brought online in 2004. During the past 21 years of operation, numerous repairs have been made to pumps, lines, valves, and building components to keep these systems in operation. The sodium hypochlorite system has over 60 documented failures resulting in chemical release and hazardous clean up situations. This system has gone beyond its expected life cycle and presents an increased risk of employee exposure and injury along with the risk of environmental contamination.

The current sodium hypochlorite bulk storage tank is in the same structure as the sulfuric acid bulk storage tank, only separated by a fiberglass wall. While the bulk storage tanks have served the plant since 2004, there has always been potential for a combined spill creating chlorine gas. By erecting a new sodium hypochlorite bulk storage tank away from the sulfuric acid bulk storage tank, the potential is greatly reduced.
The sodium hypochlorite dosing system (pumps, valves, piping, electronic controls) is degraded to the point of approaching damage beyond repair. On many occasions operators have discovered leaks. Vapors from sodium hypochlorite are dangerous and require operators to ensure this space is completely ventilated prior to entering the space. The current building is in a similiar condition and requires replacement.

Investment Type	Generation	Planning Portfolio	Covert
Facility	Covert / Covert		
Executive Summary	The project involves replacing the existing sodium hypochlorite bulk storage tank, dosing system and the building housing the dosing systems at the Covert Generating Company. The current sodium hypochlorite system, in operation since 2004, has experienced over 60 documented failures, leading to chemical releases and hazardous cleanup situations. The system has surpassed its expected life cycle, posing increased risks of employee exposure, injury, and environmental contamination. Objectives: The primary objective is to replace the aging sodium hypochlorite bulk storage tank, dosing system and housing structure to mitigate the risks associated with chemical spills and exposure to hazardous vapors. By relocating and separating the bulk sodium hypochlorite tank from the bulk sulfuric acid tank (both tanks are currently housed in same building only separated by fiberglass wall), the potential for a combined spill creating chlorine gas is significantly reduced. The recommended alternative is to replace/relocate the sodium hypochlorite bulk storage tank, replace/relocate the sodium hypochlorite dosing system including headers from the dosing system to the three cooling towers, and replace/relocate the sodium hypochlorite fiberglass housing/building. Draft Forecast$2,158,858 Between Jan 2026 and Dec 2027 Model Assumptions: There is a 10% probability of realizing a $50,000 to $150,000 risk based on discussions with plant personnel and equipment history. Additionally, there is a 3% chance of realizing a risk of a recordable injury due to exposure to chlorine gas from a potential mix between sulfuric acid and sodium hypochlorite.		
Last Approver		Approval Date	

Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 3
	Rate Case Mapping	Gas Generation
	EPM Managed	No
	Outage Type	Site
	Scope	CGS - Plant Replace Sodium Hypo storage tank and Building Replace tank. Replace pump skid and building.
	Objectives	CGS - Plant Replace Sodium Hypo storage tank and Building Benefits: Cooling tower bleach injection system material condition is improved by replacement with more robust materials and safety concerns are addressed by relocating storage vessel. Performance of cooling towers is improved by more efficient use of biocide. Necessity / Current issues and Deficiencies: 1. Pipe materials: the existing CGS cooling tower biocide (bleach) pump skid and associated piping are in poor material condition, have been source of multiple failure in the past, and continue to be at significant risk. CPVC piping joints have degraded due to oxidation. Replacing all CPVC with PVDF (Kynar Pipe or similar) will significantly reduce risk of leaks and improve material condition. Kynar pipe uses thermal welds as opposed to glues. 2. Location: the current locations of the bleach bulk storage tank and pump skid are too close to the cooling tower sulfuric acid injection bulk tank and pump skid. The bulk bleach and acid storage tanks are in the same building and only separated by an un -sealed fiberglass wall with the bleach tank fill line routed directly through the sulfuric acid bulk tank room. Bleach mixed with any acid will release a toxic chlorine gas. Relocating the bleach bulk tank and pump skid to an area NE of the ammonia storage tank will provide better physical separation of the two chemicals and significantly reduce risk of a catastrophic environmental/safety incident. Additionally, both bleach and acid tanks are FRP-type materials with limited life; typically, 10-15 years. The tanks were installed in ~2003. See sketch below. 3. Bulk storage tank orientation: The existing 6000-gal bleach tank is oriented horizontally and located about 4-5 feet below grade whereas the pump skid is at grade. Orienting the storage tank vertically and at grade will improve pump performance (provide consistent positive head pressure). 4. Injection point: The current layout routes bleach to a single injection quill located on the SW end of each tower (discharge end). Rerouting the injection points closer to the NE end of each tower and injecting bleach via an injection manifold vs. a single quill will improve biocide performance. 5. Pipe Chase: The current system design routes bleach and sulfuric acid injection headers in the same pipe-chase from the pumps skids to towers. Separating the bleach injection header from the sulfuric acid injection header will significantly reduce risk of serious environmental/safety incidents. Consider double-walled piping for the bleach headers routed to C/Ts for leak detection. 6.
	Planner Recommended Alternative	Replace storage tank and building.
	Assumptions	Potential for chemical spill exists. 10% probability of realizing a 50k-150k risk based on discussions with Plant personnel and equipment history. Risk of injury exists from exposure to chlorine gas from a potential mix between sulfuric acid and sodium hypoclorite. 3% chance of realizing a risk of a recordable injury (Conservative estimate).

Karn 3&4 Combustion Air Heaters

Date: 07/24/2024

Prepared by: Paul Ohep

Figure 1. D.E. Karn generating station

Executive Summary

The D.E. Karn 3&4 Generating Units rely on steam-to-air heat exchangers called combustion air heaters to preheat the air entering the boiler. This process is crucial for optimizing combustion efficiency and maintaining emissions within acceptable opacity limits, especially for Karn Units #3 and #4, which lack other means of controlling particulate matter output.

Key Issues

- **Tube Failures**: Over the last five years, Units #3 and #4 have experienced repeated tube failures, leading to forced outages and reduced efficiency.
- **Operational Impact**: The reduced efficiency from plugging failed tubes has caused significant operational de-rates, including a 68 MW de-rate for Karn Unit #3 from fall 2023 to spring 2024.

Engineering Evaluations

- **Historical Repairs**: Multiple outages for repairs since 1984, with replacements and repairs showing varying success.
- **Recent Testing**: 2024 eddy current testing revealed over 25% of the tubes in non-replaced sections of Unit #4 are plugged, necessitating replacement.

Alternative Solutions

1. **Do Nothing – Cost: $23+ million.**
    - **Risks**: High probability of repeated failures, leading to extended de-rates and forced outages, substantial financial losses, and regulatory compliance challenges.
2. **Plugging Individual Failed Tubes – Cost: Up to $10 million**
    - **Risks**: High recurrence risk of tube failures, frequent outages, cumulative financial impact of at least $10 million over seven years, and potential non-compliance with opacity and emissions standards.
3. **Complete Combustion Air Heater Replacement – $4.4M for Karn 3, $4.4M for Karn 4**
    - **Cost**: $8,800,000 total for replacing the air heaters in both units (12 heaters total).
    - **Benefits**: Enhanced reliability, improved efficiency, and ensured regulatory compliance, avoiding projected capacity revenue losses of over $23 million. This proactive approach addresses the root cause of failures, providing a long-term solution for operational efficiency and cost savings.

Conclusion

The "Do Nothing" option presents significant financial, operational, and regulatory risks. Plugging individual failed tubes offers a short-term, high-risk solution with substantial cumulative costs. The complete replacement of combustion air heaters in both Karn Units #3 and #4 is the most viable long-term strategy, ensuring reliable performance, compliance with regulations, and significant cost savings.

Financial Summary

Funding Type:	Capital
Estimated Total Cost:	$8,800,000 ($4.4M for Karn 3, $4.4M for Karn 4)

Proposed Start Implementation Year and project span

2024, four-year span. Completion in 2027.

Rate Case Summary

- Karn 3 project **is** included in the current electric rate case. The bridge period amount is $2.2M
- Karn 4 project **Is NOT** included in the current electric rate case.

Problem Description

The D.E. Karn Generating Station, which utilizes natural gas and oil, employs steam-to-air heat exchangers known as combustion air heaters to preheat the ambient air entering the boiler. This preheating process is essential for optimizing combustion efficiency. Specifically, Karn Units #3 and #4 rely heavily on consistent air intake temperature to fine-tune the combustion air-fuel mixture, crucial for maintaining emissions within acceptable opacity limits and ensuring efficient heat rates as they do not have any other means of controlling the output of particulate matter.

Key Issues

- **Tube Failures**
  - Units #3 and #4 have repeatedly experienced tube failures in the combustion air heaters over the last five years.
  - Failed tubes require immediate plugging and can result in forced outages if they trip the unit or necessitate immediate removal from service.
  - Plugging reduces the efficiency of the air heaters, leading to operational de-rates and inefficiencies.
- **Operational Impact**
  - Reduced efficiency of the air heaters due to tube plugging leads to significant operational de-rates.
  - From fall 2023 until spring 2024, Karn Unit #3 operated with a 68 MW de-rate due to two combustion air heater sections being out of service.

Engineering Evaluations

Extensive evaluations and testing have highlighted the necessity for addressing the issues with the combustion air heaters:

- **Historical Outages and Repairs**
  - Multiple outages have been required for repairs from 1984 through 2024.
  - Records indicate replacements in 1988 and 1990, with further repairs in 1999 showing minimal tube plugging in those sections.
- **Recent Eddy Current Testing (2024)**
  - Testing revealed that over 25% of the tubes in the non-replaced sections of Unit #4's air heater are plugged.
  - Industry standards suggest considering replacement when more than 10% of the surface area is plugged.

Conclusion

The recurrent tube failures and significant plugging in the combustion air heaters of Karn Units #3 and #4 have led to efficiency losses and operational de-rates. The historical data and recent testing highlight the urgent need for comprehensive solutions to address these issues, ensuring regulatory compliance and operational efficiency.

Alternative Solutions/Alternatives Considered

1. Do Nothing – Cost: $23+ million

Choosing the "Do Nothing" option for addressing the combustion air heater issues in Karn Units #3 and #4 presents significant risks and operational challenges. Historical data and predictive maintenance records highlight the recurring nature of these failures and their substantial impact on plant performance.

Historical Forced Outages and De-rates

1. **Frequency of Forced Outages/De-rates**
    a. **Past Incidents:** There have been multiple forced outages and de-rates in the last five years due to issues with the combustion air heaters in Karn Units #3 and #4.
    b. **Duration of Forced Outages:** Forced outages typically lasted for 2 weeks.
    c. **Duration of De-rates:** The last de-rate in unit 3 extended over a period of 6 months from fall of 2023 until spring of 2024.
    d. **Magnitude of De-rates:** The de-rates have caused a reduction of 68 MW in output.
    e. **Timing:** Forced outages occurred in late summer, while the extended de-rate lasted from fall until spring.

2. **Projected Impact of Future Failures**
    a. **Expected De-rate Magnitude:** Future failures are anticipated to result in a de-rate of 68 MW for either Karn 3 or 4.
    b. **Duration of De-rate:** The de-rate will persist until an outage allows for the failed tubes to be plugged or replaced. For cases where 2 out of 3 sections are out of service, the de-rate will last until the combustion air heaters are replaced. For Karn Unit #3, due to the extensive lead times for tube bundles and headers, the forced outage is expected to last approximately 5 months.

Procurement and Installation Challenges

- **Lead Time for Replacement Parts:** The lead time for obtaining replacement fin tubes is approximately 5 months from the receipt of a purchase order.
- **Installation Duration:** The installation duration for the replacement components would extend the de-rate/outage period, incurring additional costs compared to a planned replacement.
- **Seasonal Considerations:** Karn Units #3 and #4 operate as peaker plants, meaning they are primarily utilized during periods of high demand and high power prices. Forced outages or de-rates occurring during these peak periods (late summer and high-demand seasons) can severely impact the plant's ability to generate revenue and meet energy demands.

Risk Analysis of Failure

- **Probability of Failure:** Based on historical performance and current predictive maintenance records, including thermography, vibration analysis, and eddy current testing, failures are very likely to occur within the next 1-3 years.
- **Financial Impact:** Prolonged de-rates and outages during peak periods when the plant is expected to operate can lead to substantial financial losses due to reduced power generation and higher costs of emergency repairs.

Regulatory Compliance

Failure to maintain emissions within acceptable opacity limits due to inconsistent air intake temperatures can result in non-compliance with environmental regulations.

- **Opacity Permit Requirements potential violation:** Our de-rate is based on staying below the opacity limit of our flue gas output. Without the project, we will not be able to reach full load without violating our opacity permit requirements for particulate matter.
- **Specific Regulations:** The opacity permit requirements, which control the emissions of particulate matter, will be violated if the combustion air heaters are not operating within their design specifications.
- **Past Violations:** We have violated these requirements in the past.
- **Consequences:** Past violations have led to regulatory scrutiny.
- **Fines:** Non-compliance with the opacity permit can result in significant fines.
- **Estimated Costs:** The exact cost of fines can vary, but non-compliance typically incurs substantial financial penalties.
- **Enforcement Actions:** If the opacity permit is violated, there is a risk of enforcement actions, up to and including the potential revocation of our operating license.
- **Impact:** Revoking our operating license would lead to an immediate and indefinite shutdown of the plant, severely impacting our operational capacity and financial performance.

Capacity Value Potential Loss Impacts - $23M+ in potential capacity losses:

If no action is taken to address the issues with the combustion air heaters in Karn Units #3 and #4, there is a high potential for capacity revenue loss. The following scenarios outline the potential financial impacts under different forced outage and de-rate conditions.

Scenario 1: Five-Month Forced Outage

In the event of a five-month forced outage due to the need for replacing the entire combustion air heater, the following capacity losses are anticipated. This scenario assumes the outage occurs at Karn 3, and the table below details the projected capacity loss and associated revenue loss over three years.

Applying the same parameters as before but extended the timeframe to 5 months rather than 2 weeks. This scenario projects a loss of 40 ZRCs over a span of 3 years, with an associated capacity value impact of approximately $23.5 million for a single unit.

Five-Month Forced Outage scenario.

Year	Planned Capacity (ZRCs)	Lost Capacity (ZRCs)	Delta Capacity (ZRCs)	Loss Capacity Revenue
2023	288.1	0	288.1	$0
2024	288.1	0	288.1	$12,142,298
2025	288.1	39.992	248.108	$3,813,284
2026	288.1	39.992	248.108	$3,813,284
2027	288.1	39.992	248.108	$3,813,284
2028	288.1	0	288.1	$0
Total				**$23,582,149**

Table 2. Capacity losses summary for Karn single unit five-month forced outage.

Scenario 2: Continuous 68 MW De-rate Until 2031

If it is decided not to repair a potential failure and to operate with a 68 MW de-rate until 2031, the following capacity losses are anticipated. This scenario assumes a 68 MW de-rate at Karn 3 and utilizes a capacity value at 75% of CONE/ZRC. The yearly cost would be approximately $2.6 million, amounting to $17,984,981 over 7 years.

CONE = $127,135

75% CONE = $95,351

Table 3: Capacity cost summary for a 68MW single unit derate:

	ICAP	ZRC
Summer:	594	216
Fall:	596	254
Winter:	613	365
Spring:	602	118
Average:	601	238
% ZRC		40%
MW Risk		68
ZRC Risk		27
Capacity Risk		$ 2,569,283

Conclusion

The “Do Nothing” option presents significant risks and consequences. The historical data and predictive maintenance records indicate a high probability of repeated failures, leading to extended de-rates and forced outages. These issues result in substantial financial losses, operational inefficiencies, and potential regulatory compliance challenges. The extended lead times for procuring replacement parts further exacerbate the situation, making emergency repairs costlier and prolonging the outage periods. Consequently, not addressing the combustion air heater issues proactively can lead to critical operational disruptions, especially during peak demand periods.

2. Plugging individual failed tubes – Cost: Up to $10M

This option involves plugging individual failed tubes in the combustion air heaters of Karn Units #3 and #4 as they occur. This approach provides a short-term solution to manage immediate failures but comes with significant operational and financial risks due to the likelihood of repeated failures and subsequent forced outages. This approach will result in a forced two-week outage per incident.

Process and Cost

- **Detection and Repair:** Crews will enter the space to identify the failed tubes through testing, plug the identified tubes, and return the unit to service.
- **Outage Duration:** Each repair cycle will necessitate a forced outage of approximately 2 weeks.
- **Labor Cost:** The typical cost for each outage, including contractor labor and associated expenses, is estimated at $30,000 per event.

- **Capacity value Costs:**
  - Each two-week forced outage carries an additional cost of $1,053,670 in lost capacity revenue.
  - For the purposes of this analysis, typical losses from a seasonal or current accreditation standpoint were considered. The figures for Karn 3 were employed in the computations due to its greater capacity accreditation. This involved a straightforward computation of lost ZRCs. However, if Tier 2 hours are during peak times, the impact could be significantly more severe.
  - The financial impact would result in ~4 ZRC loss for 3 years, equating to ~$1.1M loss. This again, is worst case scenario for Karn 3 only; if the failure happens on both units simultaneously, it would be around double the losses.
  - Table 1 below details the projected capacity loss and associated revenue loss over three years.

Two-Week Forced Outage scenario capacity losses.

Year	Planned Capacity (ZRCs)	Lost Capacity (ZRCs)	Delta Capacity (ZRCs)	Loss Capacity Revenue
2023	288.1	0	288.1	$0

Year	Planned Capacity (ZRCs)	Lost Capacity (ZRCs)	Delta Capacity (ZRCs)	Loss Capacity Revenue
2024	288.1	0	288.1	$0
2025	288.1	3.683	284.416	$351,223
2026	288.1	3.683	284.416	$351,223
2027	288.1	3.683	284.416	$351,223
2028	288.1	0	288.1	$0
Total				**$1,053,670**

- Table 1. Capacity losses summary for Karn single unit two-week forced outage

Frequency and Impact of Repairs

- **Immediate Recurrence Risk:** After the unit is returned to service, there is a high likelihood of additional tube failures occurring shortly thereafter, potentially leading to repeated forced outages similar to the incidents experienced in 2022.
- **Operational Disruption:** The repeated need for repairs can lead to significant operational disruptions and inefficiencies, with frequent outages impacting overall plant performance and reliability.

Detailed Considerations

- **Cumulative Financial Impact:**
  - Over the next seven years, it is expected that this scenario will occur around once a year and potentially more frequently after year 5, leading to a cumulative cost of around $10 million at a minimum when considering the likelihood of repeat failures.
- **Operational Impact**
  - **Efficiency Loss:** Continuous plugging of individual tubes reduces the overall efficiency of the combustion air heaters, leading to de-rates and suboptimal performance.

Summary

Advantages:

- **Lower Immediate Cost:** Individual repair events are relatively low-cost ($30,000 per outage + ~$1M in capacity costs).
- **Quick Return to Service:** Units can be returned to service relatively quickly (2 weeks per event).

Disadvantages:

- **High Recurrence Risk:** High probability of subsequent tube failures leading to repeated outages.
- **Operational Disruption:** Frequent outages disrupt power generation and reduce overall efficiency.
- **Cumulative Cost:** Over time, the cumulative financial impact of repeated outages, including capacity revenue losses, can be significant, amounting to a minimum of $10 million over seven years.
- **Regulatory Compliance Risk:** Continued operation with frequent failures may risk non-compliance with opacity and emissions standards.

3. Combustion Air Heater replacement: $4.4M for Karn 3, $4.4M for Karn 4

Overview

Given the significant and recurring issues with the combustion air heaters in Karn Units #3 and #4, a comprehensive replacement of the air heaters is proposed. This option addresses the root cause of the frequent failures and operational inefficiencies, providing a long-term solution to ensure reliable performance and regulatory compliance. The total cost for replacement is estimated at $5 million for Karn Unit #3 and $3 million for Karn Unit #4.

Total Cost of Replacement

- **Karn Unit #3:** $4,400,000
- **Karn Unit #4:** $4,400,000
- **Total Replacement Cost:** $8,800,000

Justification for Replacement

1. Historical Issues and Recurring Failures

- **Frequent Outages:** Karn Units #3 and #4 have experienced multiple forced outages and de-rates over the past five years due to tube failures in the combustion air heaters.
- **High Maintenance Costs:** The repeated need for repairs, including plugging individual tubes, has led to significant maintenance costs and operational disruptions.

2. Long-Term Benefits of Replacement

- **Enhanced Reliability:** Replacing the combustion air heaters will eliminate the frequent tube failures, ensuring consistent and reliable operation of the units.
- **Improved Efficiency:** New air heaters will restore the units to their optimal performance levels, reducing the risk of de-rates and maximizing power generation capacity.
- **Regulatory Compliance:** Ensuring the air heaters operate within their design specifications will help maintain emissions within acceptable limits, complying with regulatory requirements and avoiding potential fines.
- **Significant Cost Savings:** By investing $8 million in the complete replacement of the combustion air heaters at Karn Units #3 and #4, Consumers Energy can avoid projected capacity revenue losses of over $23 million if no action is taken. This proactive approach ensures long-term operational reliability, efficiency, and regulatory compliance, ultimately providing a cost-effective solution compared to the cumulative costs and risks associated with the "Do Nothing" or emergent repair options.

Scope of Work

Replace the Combustion air heaters for both Karn 3 and 4 units. Below is a timeline indicating the years and installations of Combustion air heater sections for Karn 3 and 4.

		K3	K4	Plus
2025	Spring		Combustion Air Heater (AA & AC Sections)	Tube and headers order
	Fall		Combustion Air Heater (AB Section)	
2026	Spring		Combustion Air Heater (BA & BC Sections)	
	Fall	Combustion Air Heater (AA & AC Sections)		
2027	Spring	Combustion Air Heater (AB & BA Sections)	Combustion Air Heater (BB Section)	

Funding and Timing

- Funding has been previously committed for this project: $1.3M in 2024
- No outage is required for this project.
- Desired implementation year: 2024, last year spend 2027

System Engineer

- System Engineer: Craig Jeske

Conceptual Estimate

Year	Loaded Cost	Description
2024	**$1,300,000**	Engineering and install for K3 BB, BC sections.
2025	**$2,500,000**	Engineering and install for K4 AA, AB, AC sections, tube and headers order for 2026.
2026	**$2,850,000**	Engineering and install for K3 AA, AC, sections. Engineering and install for K4 BA, BC sections.
2027	**$2,150,000**	Engineering and install for K3 AB, BA, sections. Engineering and install for K4 BB section.

Total Cost: $8,800,000

Asset Strategy Approval Comments

The Asset Strategy Group strongly recommends approval based on cost-benefit analysis.

GEN001769	**2026**	**1**	**Literal**

Investment Name	Scenario
Karn 4 - Ductwork Exp Joint Replacement - ID Fans to Stack	**Draft**

Value Function	**Consumers Energy Value Function**

All expansion joints between the ID Fans and the Stack are suspected to be severely failed and past end of life based upon condition of expansion joints found during the Karn 3 Breeching project.
The furnace flue gas exits the boiler and gets pulled by the induced draft fan out through duct work in negative pressure until it reaches the Induced draft fan. Once exiting the induced draft fan the flue gas is pushed under pressure up the ductwork to the chimney stack where the proposed expansion joint replacement is located. When the flue gas is under pressure it is an environmental regulatory risk to leak into the atmosphere.
If there are leaks in the outlet side of the ID fan duct to the chimney, unmonitored flue gas is escaping to the atmosphere and violating the Operating Permit. Regulatory fines could be assessed up to removing the unit from service.

Investment Type	Generation	Planning Portfolio	Karn - Gas/Oil Generation
Facility	Karn / Karn		

Executive Summary

Project Overview
The project aims to replace all expansion joints between the ID Fans and the Stack, which are suspected to be severely failed and past their end of life. This is based on the condition of expansion joints found during the Karn 3 Breeching project. The furnace flue gas exits the boiler and is pulled by the induced draft fan through ductwork under negative pressure until it reaches the fan. Once exiting the fan, the flue gas is pushed under pressure up the ductwork to the chimney stack. Leaks in this system pose an environmental regulatory risk and could result in regulatory fines or removal of the unit from service.

Draft Forecast$2,620,001 Between Jan 2026 and Dec 2026

Scope
Replace all expansion joints and entry doors between the ID Fans and the stack.
Objectives
Mitigate forced shutdown and regulatory risk.
Return the equipment to its original standard.
Ensure regulatory compliance with environmental operating permits.
Alternatives
Recommended: Replace ductwork.
Historical Engineering Inspections: Several repairs have been made to the ductwork based on past inspections.
Age of Current Expansion Joints: The current Karn 4 expansion joints are 50 years old.
Regulatory Compliance: Expelling flue gases to the atmosphere bypasses the Continuous Emissions Monitoring System, leading to EGLE violations and potential shutdowns until resolved.
Model Assumptions
If no action is taken and leaks are found, the operating permit for the unit could be jeopardized, leading to environmental fines and forcing both units offline.
There is a 75% probability of expansion joint failure causing unmonitored flue gas to enter the atmosphere, resulting in a 300 MW derate followed by a 1-week 1221 MW derate with both Karn 3 and 4 down for repairs.
Performing this project will avoid O&M inspection costs of up to $20K, including scaffolding and unit outage expenses. Repairs based on inspection findings could add a minimum of $30K. The total $50K will be divided over 6 years, amounting to $8333 annually.

Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 3
	Rate Case Mapping	Peakers
	EPM Managed	No
	Outage Type	Unit - Plant
	Scope	This project will replace all expansion joints and entry doors between the ID Fans and the stack.
	Objectives	mitigate forced shutdown and regulatory risk Returning the equipment to original standard. Ensuring regulatory compliance with our environmental operating permit.
	Planner Recommended Alternative	replace expansion joint Historical engineering inspections have led to several repairs in the duct work Age of current Karn 4 expansion joints are is 50 years The expelling of flue gases to the atmosphere/environment bypasses the Continuous Emissions Monitoring System which will cause EGLE violation that lead to shutting the unit down until the condition is resolved.
	Assumptions	If chosen to do nothing, and leaks in the expansion joint are found the operating permit for the unit could be in jeopardy as well as environmental fines. Because of the location, both units would be forced offline. 75% probability of expansion joint failure causing flue gas to enter the atmosphere unmonitored makes it high consequence in which would be an immediate 300 MW derate followed by a 1-week 1221 MW derate with both Karn 3 and 4 down for an inside repair. By performing this project, we will avoid O&M inspection of the ductwork (up to $20K) which includes a large expense of scaffolding and a unit outage. Repairs based on inspection findings could be an additional $30K minimum. $50k will be divided by 6 years for a yearly amount of $8333.

Karn 4 post-fire remediation 2025-2026	**Draft**

Value Function	**Consumers Energy Value Function**

In the original Karn 3&4 plant design, startup transformer bank (#8), fed by the grid, is used to power up large fans and pumps until the unit is synchronized and starts putting Megawatts out on the grid thru the main Generator Step-Up Transformer. At that point, the plant is switched over to feed its own power thru the station power transformers and Megawatt output may be increased to full load.

During the 2025 Karn 4 main transformer (GSU) fire, the unit 4 station power transformers X, Y and Z nearby also suffered damage. The bus connecting the station power transformers to the plant was burned away. This bus was attached to the transformers thru porcelain terminal bushings. The porcelain was busted as the bus fell down. The internal windings of these three transformers tested ok after the fire, but the bushings need to be replaced to make them useable. Furthermore, the heat of the fire has deformed some of the oil seals on the transformers. Between these small oil leaks and the compromised bushings, it is urgent that this be addressed before winter, when cold temperatures could make leaks bigger, risking more oil spilling out and moisture contamination getting in.

The #8 bank is sized to provide Unit 4 station power and start Karn 3; however it is not sized to provide station power for both units while online. Thus, Karn 3 station power is critical to achieving full load. If one of unit 3 station power transformers failed, Karn 3 would be derated half load until the failed transformer was replaced. Procuring a replacement transformer typically takes up to three years.

Investment Type	Generation	Planning Portfolio	Karn - Gas/Oil Generation
Facility	Karn / Karn		
Executive Summary	The 2025 Karn 4 GSU fire damaged three Unit 4 station power transformers (X, Y, Z), destroying the connecting bus, breaking porcelain bushings, and deforming transformer oil seals. While internal windings remain intact, the compromised bushings and seals pose an urgent reliability and environmental risk—particularly heading into winter, when moisture intrusion and oil leaks could render all three transformers unusable. Loss of these transformers would eliminate critical station power capacity, increase dependency on the aging #8 cranking transformer, and create operational derates of up to 300 MW for multiple years. Objectives Mitigate forced-outage risk, Prevent equipment loss from moisture contamination, Restore reliable and redundant station power capability Reduce operational dependency on the #8 cranking transformer Operational Performance & Outage Avoidance Reduces downtime from 3 months to ~3 weeks if a Karn 3 transformer fails. Creates three like-kind spares for Karn 3, replacing the spare lost in the fire. Avoids multi-year (up to 3-year) 300 MW derates at Karn 3. Environmental Protection Eliminates oil-spill risk from heat-damaged seals and valves. Prevents costly soil contamination events similar to the $136k cleanup after the GSU fire. System Readiness & Plant Performance Enables zero-downtime response to a station power transformer failure once the bus is rebuilt. Reduces the failure probability of the 50-year-old #8 cranking bank (from ~75% to 25%). Restores original design configuration allowing Karn 4 to reliably supply its own station power with controllable voltage for critical plant loads. Improves stability for critical auxiliaries (fans, pumps, compressors, etc.) that were challenged during cranking-bank operation. Planner Recommended Alternative Avoids the need for a costly spare transformer purchase ($2M-$5M based on recent similar projects) Avoids 300 MW derates associated with multi-year transformer procurement Model Assumptions and Risk Considerations #8 cranking bank is 50 years old (designed for 20) and now carries full auxiliary load, with an estimated 50% failure probability within six years. If the cranking bank fails, Unit 4 would be unavailable for years while a replacement is procured. If bushings are not replaced, winter moisture intrusion will destroy all three Unit 4 transformers, costing ~$2M each plus multi-year derates. Oil-seal degradation is expected to worsen in winter (90% probability), raising risk of environmental contamination and cleanup costs.

Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 2
	Rate Case Mapping	Gas Generation
	EPM Managed	Yes
	Outage Type	Unit - Plant
	Scope	replace transformer
	Objectives	mitigate forced outage risk Benefits of this project include: Restore three station power transformers to usable condition. Life extension by replacing parts worn out by 50 years of service. Significantly reduce the chance of in service failure by installing new bushings. Prevent damage to the transformer windings by changing bushings now, rather than wait for moisture to be pulled in during winter temperature drops. Reduce down time from 3 months to 3 weeks in the event that a Karn 3 station power transformer fails. Serve as three like and kind spare transformers for Karn 3, replacing the spare station power transformer that was destroyed in the fire. By being identical to the Karn 3 transformers in service, it simplifies and minimizes cost of transformer(s) swap if needed. Eliminate the environmental risk of oil spill by replacing oil seals and valves. Make the transformers ready for reconnect to the plant following replacement of the bus damaged by fire. Benefits of this final phase of restoration include: Further reduction of downtime for failure of a station power transformer from 3 weeks to zero. By having both Karn 3 and Karn 4 station power connected, one of them could trip for a single transformer failure and station power for that unit would be transferred back to the cranking transformer bank, allowing full load of both units to be sustained. Relief for the cranking transformer bank from having to spare Karn 4 station power. This would reduce the chance of failure for the 50 year old cranking bank from 75% to 25%. Restoration of original plant configuration to allow plant to feed its own station power to Karn 4 so that it can reliably power critical auxiliary loads without voltage drop.

Value Function	**Consumers Energy Value Function**

	Planner Recommended Alternative	Replace bushings in Unit 4 station power transformers: Lowest cost option providing benefit the soonest. Avoids the $2M capital cost to buy a new spare transformer and avoids the O&M cost of being derated 300 MW for three years and avoids the added cost of engineering a different style spare transformer install if needed. Electrical Auxiliary Load Calculations by Commonwealth Associates Inc. dated April 6, 1972 show that the #8 cranking bank is sized to spare unit 4 and start unit 3. A test run demonstrated unit 4 can reach full load on the cranking bank, but as of this writing, starting unit 3 at the same time has not been attempted. During the test run, voltage on the 480V buses was depressed enough to reduce the performance of the instrument air compressor and contribute to a unit trip. Running on the cranking bank, voltage in the plant is subject to the condition of the system; we cannot adjust it especially now that Karn 1&2 is decommissioned. Whereas if the plant is running on its own station power, the voltage can be adjusted by adjusting generator voltage. Thus, the plant was designed to operate on its own station power as a more reliable and optimum voltage source for the critical loads such as boiler fans, vacuum pumps, condensate pumps, circulating water pumps, air compressors, etc. The #8 cranking bank was tested in 2024 and found to be in fair condition considering it is 50 years old and was designed to last 20 years. The long life is attributed to the infrequent loading of the bank only during startups. Now that we are depending on it to carry full auxiliary load of a unit, this elevates the risk of an end of life failure.
	Assumptions	If the #8 cranking bank failed, the only option is to backfeed thru a unit. It could take a couple weeks to build scaffold and remove generator links from Unit 4, so that it could be used to backfeed power for starting Unit 3. At that point Unit 4 would be unavailable for at least 3 years while a replacement cranking transformer is procured. 50% probability of failure in the next 6 years being that these are 50 years old. If the bushings are not replaced in the Unit 4 station power transformers, moisture will get into the windings this winter, resulting in a total loss of the X, Y, Z transformers. To replace these transformers, it would cost close to $2M each and take three years. In the event that one of the Karn 3 station power transformers fails, Karn 3 would be derated to half load (300MW) for 3 years. These transformers are 50 years old, twice exceeding their design life. So I give it a 50% chance of failure in the next 6 years. Also, if the bushings are not replaced, the slow oil leaks from the transformers observed now, could turn into large leaks at some point during the winter when seals shrink further. I give this a 90% chance of happening. While the transformers are in containment, that containment is filled with earth that would have to be disposed of and replaced if soaked in oil. Contaminated soil cleanup after the Karn 4 GSU fire cost $136k.

Karn 4 ID Fan Inlet Dampers

Date: 10/07/2024

Prepared by: Paul Ohep

Figure 1. D.E. Karn generating station

Docusign Envelope ID: 03B3A894-68C9-4347-A307-D20C47324D10

Executive Summary

The Karn Unit 4 Induced Draft (ID) Fan Inlet Damper Replacement project is critical to ensuring reliable and efficient operation of the unit. The current ID fan inlet dampers, which are essential for controlling the boiler draft, are aging and have caused multiple forced outages and significant capacity de-rates over the past five years. These failures have resulted in high operational costs, inefficiencies, and risks of continued disruptions during peak operational periods. Replacing the dampers is a proactive investment that will eliminate these risks and provide long-term operational stability.

The project's estimated total cost is **$3 million**, to be spent in 2025, including **$2.3 million** for labor and **$700,000** for materials. This one-time investment will deliver substantial financial and operational benefits, positioning the unit for reliable operation through the remainder of the plant service life.

Key benefits of this project include:

- **Avoidance of Capacity Losses**: Without replacement, Karn Unit 4 would continue to experience forced outages and de-rates, resulting in cumulative capacity losses. Based on two failures per year, these losses are projected to reach approximately **$4.55 million** by 2031. Replacing the dampers will prevent these escalating penalties, providing significant cost savings over the long term.
- **Avoidance of Recurring O&M Costs**: The current reactive repair strategy has led to annual maintenance costs exceeding **$50,000**. With new dampers in place, these recurring costs will be eliminated, further improving the plant's financial performance.
- **Fuel Savings from Lower AGC Load**: Replacing the dampers is expected to lower the minimum load limits by **10 MW**, allowing the unit to operate more efficiently. This reduction in the load floor will result in additional fuel savings, further contributing to the overall cost-effectiveness of the project.
- **Improved Operational Flexibility and Reliability**: The replacement will restore full control over boiler draft, reducing the risk of trips and improving the plant's ability to operate flexibly during periods of fluctuating demand. This is particularly important during peak summer seasons when the grid is in critical need of generation.

In conclusion, while the initial capital investment is significant, the replacement of the Karn Unit 4 ID fan inlet dampers will eliminate ongoing capacity losses, reduce operational costs, and deliver substantial fuel savings. This project is essential for maintaining the unit's long-term reliability and maximizing its operational and financial performance through 2031.

Financial Summary

Funding Type:	Capital
Estimated Total Cost:	$3,000,000

Proposed Start Implementation Year and project span

Implementation scheduled for Fall of 2025.

Docusign Envelope ID: 03B3A894-68C9-4347-A307-D20C47324D10

Problem Description

The Karn Unit 4 Induced Draft (ID) fan inlet dampers play a crucial role in regulating the fan load and maintaining a negative draft in the boiler, which is essential for safe and reliable operation. Over the last five years, the dampers have experienced multiple failures, leading to forced outages and significant de-rates, indicating the urgent need for replacement.

Key points regarding the failure history:

- **Frequent Repairs**: Repairs have been needed during both the **spring and fall outages** for the last five years, with some repairs being more extensive than others. The consistent repair needs point to the deteriorating condition of the dampers.
- **De-rates and Outages**: When the dampers fail, the unit has experienced de-rates as high as 300 MW, with repairs typically taking about a week.
- **Forced Outages**: Even the easiest repairs, such as linkage repairs, have resulted in forced outages. Recently, a forced outage was taken to repair an ID fan damper linkage, requiring a **two-day outage**. More complex repairs, such as internal damper work, take significantly longer and are more costly.
- **Internal Repairs Require Scaffolding**: All internal repairs to the ID fan inlet dampers require scaffolding, adding significant costs. Vendor quotes for recent repairs include:
  - **$31,000 for scaffolding** in a fall 2023 repair quote.
  - **$76,000 estimate** for internal damper work in May 2024, with **$26,000 allocated for scaffolding**.

Given this failure history, we have conservatively assumed **two failures per year**—one in the spring and one in the fall. This assumption is based on the consistent pattern of repairs and forced outages over the past five years. Even minor repairs have caused forced outages, impacting the unit's reliability and availability.

Financial Losses

We have used a conservative estimate of **$50,000 per repair** for both internal and external damper repairs. This estimate is based on actual repair costs from recent vendor quotes and repair history listed in this section. The costs of addressing internal and external failures over the past five years highlight the growing financial burden of maintaining these aging dampers.

Considering the repeated need for internal and external repairs, **$50,000 per repair** is a **conservative assumption**. The actual costs of maintaining the aging dampers will likely increase over time as the system continues to deteriorate. By assuming two failures per year, we are accounting for the true financial burden of these recurring issues, though actual costs may exceed this estimate.

The current condition of the dampers is unsustainable. These original components, exposed to harsh operating environments, are no longer reliable. Failure is imminent, and replacement is necessary to restore proper operation and eliminate ongoing operational and financial challenges.

Docusign Envelope ID: 03B3A894-68C9-4347-A307-D20C47324D10

Alternative Solutions/Alternatives Considered

1. Do Nothing – Cost: $4,549,664 in capacity losses plus $50,000 in repair costs.

Opting to "do nothing" and forgo the replacement of the Karn Unit 4 ID fan inlet dampers would mean continuing the current strategy of performing reactive repairs when a damper fails. This approach, which has been in place for several years, relies on the use of O&M funds to repair the dampers after each failure, while also incurring de-rates and forced outages during peak demand seasons.

Key impacts of the “Do Nothing” option include:

- **Frequent Forced Outages and De-Rates**: Karn Unit 4 has tripped multiple times over the past five years due to positive pressure in the boiler or an inability to control the draft caused by failing dampers. Each of these failures results in a 300 MW de-rate, which can typically take about a week, depending on whether the issue is internal or external. Each one-week derate is expected to cost $81,244 per year in potential capacity losses and will carry an additional penalty of $81,244 for the next three years. Table 1 below summarizes the capacity loss impact of a single failure.

Metric	Value
GVTC (Unit Capacity)	614.7 MW
Seasonal Accredited Capacity (ZRCs)	273.1 ZRCs
CONE Value (75% of $127,135)	$95,351
De-Rate Impact (300 MW for 1 week)	$81,244 per year
Impact Over 3 Years (MISO rules)	$243,731 total

Table 1. Capacity losses summary for a 300MW one-week derate.

Continuing this reactive approach would also result in ongoing capacity losses. Based on past failure history of two failures per year over the last five years, it is assumed with high certainty that there will be at least two failures per year with the current equipment condition. With two anticipated failures per year, this leads to an annual impact of **$162,488**. As per MISO rules, each year’s failures will affect the following three years, compounding the losses over time. Table 2 below shows the summary of the cumulative financial losses from 2025 through 2031:

Year	Annual Capacity Loss from Current Year Failures	Ongoing Loss from Previous Failures	Total Loss for the Year
2025	$162,488	$0	$162,488
2026	$162,488	$162,488	$324,976
2027	$162,488	$324,976	$487,464
2028	$162,488	$487,464	$649,952
2029	$162,488	$649,952	$812,440
2030	$162,488	$812,440	$974,928
2031	$162,488	$974,928	$1,137,416

Table 2. cumulative capacity losses from 2025 to 2031

Docusign Envelope ID: 03B3A894-68C9-4347-A307-D20C47324D10

Total Cumulative Loss from 2025 to 2031: $4,549,664

By continuing the current strategy with two failures per year, the total cumulative capacity loss would reach approximately **$4.55 million** by 2031. This far exceeds the one-time **$3 million** investment required for a complete replacement, making the replacement option the more cost-effective long-term solution.

- **High Operational and Maintenance Costs**: The reactive repair strategy has led to annual O&M costs exceeding $50,000 for damper repairs. Replacement parts such as damper blades have a lead time of 2-3 days and repairs take up to a week. This approach has proven costly, as it does not address the underlying problem of aging dampers that operate in a harsh environment.
- **Reduced Operational Efficiency**: Due to the damper issues, Karn Unit 4 operates with a higher minimum AGC load of 70 MW—10 MW higher than Karn Unit 3. This increases fuel costs, reduces operational flexibility, accelerates wear and tear on the equipment, and limits the unit's ability to support grid stability, especially during peak demand periods.

2. Complete Replacement of ID Fan Inlet for Karn 4. Cost - $3,000,000

Selecting the option to completely replace the ID fan inlet dampers for Karn Unit 4 would provide a long-term solution to the current operational issues, ensuring reliable control of the boiler draft. The total cost of the replacement is estimated at **$3 million**, to be spent in 2025, with **$2.3 million** allocated for labor and **$700,000** for materials. This investment would provide reliable operation for the remainder of the plant's operational life.

Key Benefits:

- **Reliable Operation**: The new dampers would ensure effective and precise control of the boiler draft, eliminating the risks of positive pressure in the boiler that have caused multiple unit trips and de-rates in recent years. With new dampers, the plant can operate more efficiently, with fewer forced outages and a reduction in unscheduled maintenance.
- **Long-Term Cost Savings**: Although the initial capital investment of **$3 million** is significant, it would eliminate the recurring costs of reactive repairs, which have exceeded **$50,000 annually**. By addressing the root cause of the failures, the complete replacement would prevent the frequent outages and capacity losses that occur under the "do nothing" approach.

  In total, by 2031, the cumulative loss would reach **$4.55 million** due to capacity losses alone, not counting the ongoing repair costs. This figure starkly contrasts with the initial $3 million investment, which would prevent these escalating losses, making the replacement option more financially prudent over the long term.

- **Operational Efficiency**: Replacing the dampers will restore the unit's ability to operate with a lower AGC load, improving the plant's operational flexibility and reducing fuel consumption. This will also reduce wear and tear on the unit, leading to lower maintenance costs over time. By addressing the issues of higher AGC load (currently 70

Docusign Envelope ID: 03B3A894-68C9-4347-A307-D20C47324D10

MW, 10 MW higher than Karn Unit 3), the plant will be better positioned to support grid stability, especially during periods of fluctuating demand or increased reliance on renewable energy sources.

- **Enhanced Grid Support**: With reliable dampers, Karn Unit 4 can better support the grid, especially during peak summer seasons, when the plant plays a critical role in meeting high electricity demand. By eliminating the risk of de-rates and ensuring the unit can operate at full capacity, Consumers Energy can maximize the value of the unit during critical times of grid need.

Conclusion:

Replacing the ID fan inlet dampers is the most financially and operationally attractive option. It eliminates the recurring issues of forced outages, de-rates, and costly repairs, while ensuring Karn Unit 4 operates efficiently and reliably. This investment not only addresses the current risks but also positions the plant to deliver reliable power generation, especially during peak periods.

Zeeland Phase 2 Gas Turbine upgrades.

Date: 5/23/2025

Prepared by: Paul Ohep

Figure 1. Zeeland Generating station.

Executive Summary

The Zeeland Generating Station, a critical asset in Consumers Energy's portfolio, is set to undergo significant upgrades to enhance its performance and reliability. This project focuses on the Zeeland Phase 2 gas turbines, leveraging advanced technologies to support the transition to a more renewable energy portfolio. Importantly, this upgrade is identical in scope and design to the improvements implemented on Zeeland Units 1A and 1B, which were approved as part of the 2024 electric rate case.

Problem Description

The Zeeland Generating Station operates with a combination of four gas turbines and one steam turbine in a combined cycle configuration. These units are maintained under a Long-Term Service Agreement (LTSA) with GE, ensuring their periodic overhaul. In 2028, the Zeeland Phase 2 site is scheduled for Major Inspection outages, presenting an opportunity to implement substantial improvements. The primary goal is to replace the "hot" or combustion components of the turbines, which degrade over their 32,000-hour design lifespan.

Proposed Solution

The project proposes the implementation of two advanced technologies:

- **Advanced Gas Path (AGP)**: This technology aims to elevate the output and efficiency of the turbines by replacing existing parts with high-performance components, resulting in notable improvements in output and heat rate efficiency. Specifically, the AGP upgrade is expected to improve output by 51 MW for the entire Phase 2 plant at full/base load and enhance heat rate efficiency by 2.5%.
- **Axial Fuel Staging (AFS)**: This upgrade enhances the turbines' output turndown capability, allowing for lower load operations while maintaining emissions compliance. This flexibility is crucial as Consumers Energy moves towards a diverse energy portfolio reliant on renewable sources.

Alternative Solutions Considered

- **Do Nothing**: Maintaining the current unit configuration without upgrades would result in forfeited savings of $40.8M and a decrease in market competitiveness and operational flexibility.
- **Install AGP Only**: This option involves an initial capital investment of $51.0M, with projected incremental revenue of $121.8M through 2040 and a favorable NPV gain of $45.5M.
- **Install AFS Only**: This option was not pursued further due to significant financial hurdles and the lack of additional capacity revenue.
- **Install both AGP and AFS (recommended)**: The recommended option is to install both AGP and AFS technologies (same scope as Phase 1 project), with an initial investment cost of $55.7M. This comprehensive upgrade is expected to provide superior flexibility, emissions compliance, future market competitiveness, and standardization benefits. The potential NPV savings are estimated at $40.8M from 2025 through 2040.

- Despite the AGP-only option providing $4.7 million additional NPV savings compared to the combined AGP + AFS option, the latter remains favored due to its enhanced flexibility, compliance with emissions standards, anticipated future market competitiveness, and standardization advantages. These factors will be discussed comprehensively in the subsequent sections of the concept approval.

Funding and Timing

- **No prior funding committed**.
- **Scheduled outage required**.
- **Desired implementation year**: First year spend in 2025, installation in 2028.
- **Impact of delay**: Delaying implementation beyond 2028 poses significant risks and missed opportunities, potentially delaying benefits realization until the next major outage overhaul opportunity which is currently scheduled for 2034.

Conclusion

The AGP-AFS upgrade is a forward-thinking approach that promises significant performance enhancements, substantial long-term financial benefits, and improved adaptability to support Consumers Energy's energy portfolio. This investment is justified by the considerable potential savings and the strategic alignment with the transition to renewable energy sources.

Financial Summary

Estimated investment: **$44.9M**

Proposed Start Implementation Year and duration.

First year spend 2025, installation year 2028.

Problem Description

The Zeeland Generating Station, a key asset in Consumers Energy's portfolio, operates using a combination of four gas turbines and one steam turbine, configured as a combined cycle plant. These critical units are maintained under a Long-Term Service Agreement (LTSA) with GE, which ensures their periodic overhaul and upkeep, restoring them to near-original condition. A crucial aspect of these overhauls, conducted during major outages managed by GE, involves replacing the "hot" or combustion components of the turbines. These components typically degrade over their 32,000-hour design lifespan.

In 2028, the Zeeland Phase 2 site is scheduled for Major Inspection outages, presenting an opportune moment to undertake substantial improvements in both Phase 2 gas turbines. This project is centered around the implementation of upgraded replacement parts that significantly enhance performance and reliability.

Advanced Gas Path (AGP): This technology aims to elevate the output and efficiency of the turbines. AGP involves replacing existing turbine and combustion parts with high-performance, technologically advanced parts. The enhancement is expected to deliver notable improvements in output and heat rate efficiency, while maintaining the same level of reliability.

Axial Fuel Staging (AFS): In conjunction with AGP, AFS is another important upgrade. It enhances the turbines' output turndown capability, crucial for flexible operation. This is achieved by replacing and adding advanced combustion hardware, allowing for lower load operations while still adhering to emissions compliance. Such advancements are increasingly vital as Consumers Energy moves towards a diverse energy portfolio heavily reliant on renewable sources. The AFS technology is instrumental in ensuring that the Zeeland Phase 2 combined cycle gas turbines maintain operational flexibility to support this transition, accommodating the variability inherent in renewable energy sources.

Alternative Solutions/Alternatives Considered

1. Do Nothing – Cost: $40.8M (unrealized savings)

This alternative involves maintaining the current status quo at Zeeland Generating Station, where there is no immediate requirement to replace the turbine and combustion parts with higher performing components.

Cost Implication

- **Cost:** $40.8M (Forfeited Savings) + Forfeited AFS benefits
- **Impact:** Choosing this option results in forgoing the potential savings and benefits that could be achieved through Alternatives #2 and #3.

Detailed Analysis

- **Forfeited Potential Savings:** If neither Alternative #2 (AGP installation) nor Alternative #4 (AGP & AFS installation) is selected, Zeeland Phase 2 stands to lose potential savings $40.8M with AGP & AFS over the period from 2025 to 2040. These savings are detailed in the AGP & AFS alternative description.
- **Market Competitiveness and Flexibility:** Without implementing either of these advanced technologies, there is a significant risk that Zeeland Phase 2 will become less competitive and flexible in the rapidly evolving electrical generation market. The introduction of renewable energy sources demands greater flexibility from conventional generation assets, which this option fails to address.
- **Opportunity Cost:** The cost of this "Do Nothing" option is effectively the lost opportunity to save and improve. While not investing in upgrades might seem to save money in the short term, it equates to a considerable loss in terms of unrealized savings and market adaptability.

Opting to maintain the current setup without upgrades translates into a significant loss of potential savings and a decrease in market competitiveness and operational flexibility. This option, while seemingly cost saving, could lead to substantial opportunity costs and a failure to adapt to the changing dynamics of the energy market.

2. Install AGP only- Cost: initial capital investment of $51,011,000

This alternative entails the installation of an Advanced Gas Path (AGP) in Zeeland Phase 2's gas turbines, a significant upgrade to enhance performance and efficiency.

Financial Overview:

- **Cost:** Total customer cost of $51M over the life of the upgrade in today's dollars based on a fixed charge rate of 13.59% (Based on internal estimates incorporating contractor quotes and overhead loadings).
- **Revenue:**
  - The projected incremental revenue for this project is estimated to be $121.8M through 2040.
  - The projected incremental capacity revenue is projected to be $34.8M through 2040.
- **Impact:** The AGP only option will provide a favorable NPV gain of $45,524,000 through 2040. This is based on an Aurora internal economic model performed in February of 2025.

Table 1 below summarizes the incremental revenues and costs for the AGP only option.

Net Present Value Results	AGP Only case with 588 MW Capacity Revenue Cap
Current Nameplate Capacity (MW)	553
Upgraded Capacity (MW)	604
NPV, Incremental Energy Revenue AGP only (K$)	($121,803)
NPV, Incremental Capacity AGP only (K$)	($34,846)
NPV, Incremental Operating Costs AGP only (K$)	$60,114
NPV, Investment AGP only (K$)	$51,011
NPV, Total Value of Phase 2 Upgrade (K$)	**($45,524)**

Table 1. Revenue and costs table for AGP only option

Economics modeling assumptions:

The economic model for this option is based on the following AGP assumed features:

- Capacity value is assumed at 75% of the cost of new entry.
- Capacity accreditation is estimated at 90% for all seasons.

Output Improvement

- **Improvement:** +51MW for the entire Phase 2 at Full/Base Load, based on GE's quotes.

Heat Rate Improvement

- **Improvement:** 2.5% Efficiency Improvement across Load Range.

Components and Work Scope:

- AGP Parts: Includes all necessary AGP components, new Gas Control Valves (GCVs), and Stop-Ratio Valve (SRV). The cost is escalated from the 2025 base by 3% per year.
- Comprehensive Upgrade: The upgrade involves replacing hot parts with AGP components, transitioning from DLN2.6 combustors to DLN2.6+ to enable AGP performance enhancements, increasing the shaft torque limit rating, revising control curves, and adjusting control constants.
- Turbine Model Change: These modifications will upgrade the turbine model from 7FA.03 to 7FA.04.
- GCVs/SRV Replacement: To realize the full potential of the AGP/DLN2.6+ work, replacing the GCVs/SRV is crucial. This will also address the gas supply pressure limitations in the upper output range by reducing approximately 25 psi of pressure drop across these components.

Financial Outlook:

The AGP-only upgrade, with a comprehensive scope of work to elevate turbine efficiency and performance, represents a strategic investment towards modernizing the Phase 2 turbine. The project is anticipated to result in significant Net Present Value (NPV) savings of $45.5 million over a fifteen-year period, to 2040. This includes considerations for incremental energy and capacity revenue, along with a detailed analysis of operating costs and investment requirements.

3. Install Advance Fuel Staging only

The AFS-only option explores the introduction of Axial Fuel Staging technology to the turbines at Zeeland Generating Station, focusing solely on this upgrade without the inclusion of Advanced Gas Path (AGP) components. The AFS technology is designed to enhance combustion efficiency and reduce emissions, aligning with operational improvements and environmental compliance objectives.

Although the AFS-only upgrade offers notable operational benefits, such as enhanced emissions control, it encounters significant financial hurdles. These challenges stem from a lack of additional capacity revenue and the inability of increased energy revenue alone to cover the substantial upfront investment and ongoing operational costs. Crucially, the AFS-only strategy misses out on the considerable operational improvements associated with AGP enhancements, including a capacity boost of 51MW (total for entire Phase 2) and a heat rate improvement of 2.5%.

Based on prior experience with modeling AFS only upgrade with Phase 1 and vendor recommendations, it was decided not to look further into this option as it is not typically installed on its own and will most certainly result in losses over time (as modeled for phase 1 upgrade).

4. Install AGP and AFS – initial investment cost - $55.7M – Recommended option

This alternative proposes a comprehensive upgrade to the Zeeland Phase 2 gas turbines by installing both Advanced Gas Path (AGP) and Axial Fuel Staging (AFS) technologies.

Financial Overview:

- **Cost:** Long term financial budget of $44.9M. Total customer cost of $55,669,000 over the life of the upgrade in today's dollars based on a fixed charge rate of 13.59% (Based on internal estimates incorporating contractor quotes and overhead loadings).
- **Impact:** Potential Net Present Value savings of an estimated $40.793M from 2025 through 2040 from the upgrade. This is based on an Aurora internal economic model performed in February of 2025.

Components and Work Scope:

- **AGP Parts and Work:** AGP components include new Gas Control Valves (GCVs), Stop-Ratio Valve (SRV), and related replacement work.
- **Comprehensive Turbine Upgrade:** Incorporates the scope of Alternative #2 (AGP installation) while adding AFS components. This includes replacing hot parts with AGP components, upgrading combustors to DLN2.6+, and making necessary revisions to control curves and constants.
- **Turbine Model Change:** These upgrades will transform the turbine model from 7FA.03 to 7FA.04.
- **Enhanced Gas Supply Efficiency:** Replacement of GCVs/SRV will mitigate gas supply pressure limitations in high output ranges by reducing pressure drop.

AGP + AFS upgrade Economic benefits breakdown and assumptions:

Table 3 below shows a summary of the NPV incremental costs and revenues for this option.

Net Present Value Results	AGP+AFS full upgrade
Current Nameplate Capacity (MW)	553
Upgraded Capacity (MW)	604
NPV, Incremental Energy Revenue Full upgrade (K$)	($120,623)
NPV, Incremental Capacity Full upgrade (K$)	($34,846)
NPV, Incremental Operating Costs Full upgrade (K$)	$59,007
NPV, Investment Full upgrade (K$)	$55,669
NPV, Total Value of Phase 2 Full Upgrade (K$)	**($40,793)**

Table 3. Revenue and costs table for AGP and AFS option

Economics modeling assumptions:

The economic model for this option is based on the following AGP assumed features:

- Capacity value is assumed at 75% of the cost of new entry.
- Capacity accreditation is estimated at 90% for all seasons.

Differences between AGP only and AFG+AFS upgrades:

Tables 2 and 3 above show that, based solely on quantitative modeling, the AGP-only upgrade appears to be more valuable by $5M over the next 15 years compared to the full AGP+AFS upgrade. The reason for this is that our model doesn't assign an appreciable impact from lowering the minimum load (when adding AFS) as units are typically chosen based on mid- and max-load capabilities rather than minimum load. Dispatch decisions are made when there is an expected increase in demand.

However, when considering both quantitative and qualitative impacts, the full AGP+AFS upgrade offers significantly more value than the additional ~$4.7M provided by the AGP-only option.

Below is a breakdown of the full benefits of AGP+AFS upgrade over AGP-only option:

1. Flexibility
    - For a Renewable Grid – The flexibility that will be offered and needed in the future is difficult to model, and we believe it will be very valuable to support a grid that requires baseload generation (like Zeeland Phase 2) to respond to the flexibility required by Renewable Generation.
    - Leading to Equipment Reliability – The cost savings in equipment reliability due to cycling could be substantial in the future, with an additional investment of $4M now potentially reducing the number of future shut-downs. This reduction would be achieved by having a lower minimum load capability. The load reduction from this upgrade may become more frequent in the afternoon as more solar generation is added, necessitating two major load-following events. A lower minimum load capability could determine whether the equipment shuts down for a few hours or remains at minimum load (spinning reserve).

2. Emissions Compliance – AFS will be valuable operationally and legally / for regulatory factors because during start-up, AFS will help Zeeland Phase 2 get into emissions compliance mode much earlier into the start-up process. This is important, because the Zeeland Phase 2 air permit will most likely change as it is changing for Phase 1 (due to the AGP part of the upgrades) to include much more strict emissions compliance standards during start-ups (potentially lower emissions rates but also less exceptions for start-up emissions).

3. Future Market Competitiveness – The growth rate in gas plants adding the AFS technology (and newer plants being built with the technology) is trending toward exponential. By the early 2020s, GE had only 4-5 examples of the technology being used, but 2024 saw two more installations, with 2025/2026 seeing numerous more installations according to GE as stated at the May 2024 7F Users Conference. Utilities are starting to see the major value of the flexibility offered by AFS, and as more plants

retrofit or are built new with the technology, Zeeland Phase 2's flexibility value will remain competitive with the market supporting a more Renewable grid.

4. Standardization and Capital Spares Reduction – The Full Upgrade case would standardize the parts between our Phase 1 and Phase 2 units as they would then be the exact same turbines. That benefit is somewhat difficult to quantify value-wise, but it goes a long way to benefiting reliability, troubleshooting when issues arise, and having spare parts.
5. Installation timing efficiency - Installing the AFS upgrades simultaneously with the AGP (and DLN2.6+) is recommended due to the significant amount of additional fuel routing required for the AFS upgrade.

Overall, the Full Upgrade (AGP & AFS) provides superior flexibility for supporting a grid that is going quickly to Renewables for ~$5M less value out of around $40M savings to our customers over the next 15 years.

Scope of Work

Scope of Work Activities for Erickson's and GE's Major Inspection at Zeeland Phase 2:

1. Erickson's Responsibilities:

- Provide cranes and lifting services as part of the already scheduled and budgeted GE Long-Term Service Agreement (LTSA) Major Inspection work.

2. GE Parts/Software Scope of Supply:

Advanced Gas Path (AGP) Components:

- AGP Stage 1 Nozzle Kit and Support Ring.
- AGP Stage 2 and 3 Nozzle Kits.
- AGP Stage 1, 2, and 3 Bucket Kits.
- AGP Stage 1, 2, and 3 Shroud Kits.
- Cooling and sealing air orifice modification.
- Provision of installation and modification documents.
- OpFlex Enhanced Transient Stability Model-Based Controls platform.
- Firing temperature increase and revised Model-Based Control (MBC) software changes.
- 7FA.04 length 1AO, 2FO, 2AO wheelspace thermocouples.

DLN 2.6+ Components:

- ML A033 Major Disassembly Tool Kit.
- ML 0513 Gas-Only Fuel Nozzle Assembly.
- ML 0572 Fuel Gas Emergency Stop Valve.
- ML 0701 Combustion Chamber Arrangement.
- ML 0702 Transition Piece Assembly.

- ML 0703 Combustion Liner Arrangement.
- ML 0717 Transition Piece Arrangement.
- ML 0719 Aft Combustion Case Arrangement.
- ML 0726 Combustion Tuning Piping.
- ML 1214 Spark Plug Assembly.

Gas Control Valves (GCVs) / Stop Ratio Valve (SRV):

- High Recovery Gas Control Valves (GCVs).
- Stop Ratio Valve (SRV).
- Supporting piping, conduit, and hydraulic components.
- Modifications to Gas Turbine Controls.

Axial Fuel Staging (AFS) Components:

- AFS injectors and sealing.
- Fuel delivery tubing and valving.
- Additional 5th fuel circuit and manifold for AFS.
- Manway covers.

3. GE Work Scope:

- Removal of old turbine parts.
- Installation of new AGP and AFS components.
- Modifications to existing parts as required.
- Revision of control curves and constants to integrate the new upgrades.

This comprehensive scope of work outlines the key activities and components involved in the upgrade project for Zeeland Phase 2, ensuring the successful integration of Advanced Gas Path (AGP) and Axial Fuel Staging (AFS) technologies.

Funding and Timing

- No funding has been previously committed for this project.
- A Scheduled outage is required for this project.
- Desired implementation year: First year spend 2025, installation year 2028
- Impact if the recommended implementation year is changed:
    - Delaying the implementation of Advanced Gas Path (AGP) and Axial Fuel Staging (AFS) technologies at Zeeland Phase 2 to a year beyond the recommended 2028 poses significant risks and missed opportunities. Postponing these upgrades until the next outage of opportunity, potentially 5-6 years later during the next Hot Gas Path Inspection, would result in a considerable delay in realizing the benefits for Consumers Energy's customers.
- System Engineer: Tim D. Boerema

Conceptual Estimate

Year	Loaded Cost	Description
2025	**$60,000**	Initial engineering work
2026	**$7,969,033**	25% Payment for Lump Sum
2027	**$24,834,311**	AGP/AFS Payment for Design and engineering
2028	**$12,036,656**	AGP/AFS 75% payment, installation, and closeout

Total Cost: $44,900,000

Asset Strategy Approval Comments

The Asset Strategy Group recommends approval. The AGP-AFS upgrade is a forward-thinking approach that not only promises significant performance enhancements but also substantial long-term financial benefits and improved adaptability of the turbines to support Consumers Energy's energy portfolio. This investment is justified by the considerable potential savings.

(11712) ZGS - Phase II Turbine Replacements - Owner obligations	**Draft**

Value Function	**Consumers Energy Value Function**

The Zeeland Generating Station is a gas-powered combustion turbine site consisting of four gas turbines and one steam turbine. These turbines are covered by a Long Term Service Agreement (LTSA) with GE to provide overhauls and upkeep on the units, periodically restoring them to like-new condition. The turbine rotors have a design life of 144,000 hours, at which time the rotors are required to be replaced. The rotors will have approximately 130,000 hours in 2028, and going another 32,000-hour maintenance cycle would violate the 144,000-hour Rotor Replacement requirement.

The ideal time to do the Rotor Replacement is during a Major Inspection (because the rotor is pulled for inspection), which only occurs every other 32,000-hour maintenance cycle. The first 32,000-hour maintenance cycle leads to a Hot Gas Path Inspection (HGPI, the rotor is not pulled for this work), the second 32,000-hour maintenance cycle leads to a Major Inspection (Major), and then two more 32,000-hour cycles are repeated leading to the final Major when the rotor is required to be replaced. ThetwogasturbinesatZeelandPhase2havetheirsecondMajoroutagesin2028. Therefore, the Rotor Replacement should occur during the 2028 Major. This project is to replace the turbine rotors in both Phase2 gas turbines in conjunction with the 2028 Major.

Investment Type	Generation	Planning Portfolio	Zeeland
Facility	Zeeland / Zeeland		
Executive Summary	The Zeeland Generating Station (ZGS) is a gas-powered combustion turbine site comprising four gas turbines and one steam turbine. These turbines are maintained under a Long-Term Service Agreement (LTSA) with GE, which includes periodic overhauls to restore them to like-new condition. The turbine rotors have a design life of 144,000 hours, necessitating their replacement upon reaching this threshold. By 2028, the rotors will have approximately 130,000 hours, making it imperative to replace them during the 2028 Major Inspection to avoid violating the LTSA. Draft Forecast$36,440,404 Between Jan 2026 and Dec 2028 Scope of Work: The project involves replacing the turbine rotors in both Phase II gas turbines during the 2028 Major Inspection. This includes: Incorporate various enhancements to the rotor and compressor components to improve damage tolerance, reduce wear, and maintain and improve reliability. Objectives and Benefits: •Mitigate the risk of major extended plant shutdowns. •Enable continued operation beyond 2028. •Optimize outage timing to maximize unit availability. •Ensure compliance with LTSA contract requirements. •Ensure plant reliability goals are achieved until at least 2045. •Reduce inspection requirements and increased reliability and availability. •Improved damage tolerance and robustness of the rotor. Model Assumptions: •The rotor replacement is required to continue operations beyond 144,000 hours. •Failure to replace the rotors during the 2028 Major Outage would result in Phase II ceasing operation by 2029, leading to significant financial losses. 100% chance of Phase 2 becoming inoperable in 2029 if this work is not performed, leading to forfeiting $80M of savings when comparing purchasing Zeeland Phase 2's generation on the MISO market.

Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 3
	Rate Case Mapping	Gas Generation
	EPM Managed	No
	Outage Type	Site
	Scope	Erickson's will provide cranes and lifting services as part of the GE LTSA Major Inspection work, which has already been scheduled and budgeted. GE Parts/Software Scope of Supply: Dovetail slots of forward stub shaft (FSS): Incorporate shot peening and undercut feature. Dovetail slots of wheel 1 (CW1): Incorporate shot peening. Enhanced R0 thru R8 blades: Enhanced R0 blades: Blades with a completely new airfoil design improved with: Airfoil shot peening: The full airfoil surface is mechanically peened to achieve improved tolerance to erosion, corrosion, and foreign object damage. Laser shock peening: The leading-edge root is treated with laser shock peening to provide high resistance to erosion, corrosion, and foreign object damage. Dovetail undercut: Performed on both sides of the dovetail to minimize fretting wear by mitigating stress at the edge of contact and moving the fretting area away from high stresses. Graphite coating on dovetail: Applied on both sides of the dovetail to reduce fretting wear. Squealer tip: Intended to increase rub tolerance. Enhanced R1 thru R3 blades: Same airfoil design as the original, improved with: Full airfoil shot peening. Dovetail undercut. Graphite coating on dovetail. Squealer tip (ONLY R1s). Enhanced R4 and R5 blades: Same airfoil design as the original, improved with: Full airfoil shot peening. Dovetail undercut. Enhanced R6 thru R8 blades: Same airfoil design as the original, improved with full airfoil shot peening. R12 thru R17 wheels: Incorporate round slot bottom (RSB) dovetail design, greatly reducing stress on the dovetail slot and excluding the Rotor from TIL 1972. Optimized clocking on Stages 14 thru 16 blade & wheel assemblies: The blade pattern for Stages R14 thru R16 improves stator reliability by eliminating the S14 thru S16 vane rocking phenomena. Current production Gen-V turbine Rotor spool: Incorporates the following features: Optimized air-cooling slot design on Stage 1 and 2 wheels, reducing stress cracking in the corners of the cooling slots.
	Objectives	Mitigate the risk of major extended plant shutdown. Optimize outage timing to maximize availability of the unit Ensure plant reliability goals are achieved until at least 2045.

Concept Approval Internal Report

Investment Code	Report Start Year	Number of Years	Currency Scale
GEN002026	**2026**	**3**	**Literal**

Investment Name	Scenario
(11712) ZGS - Phase II Turbine Replacements - Owner obligations	**Draft**

Value Function	**Consumers Energy Value Function**

	Planner Recommended Alternative	This scope replaces the existing rotor with a new one, providing another 144,000 hours of operation, which would enable operation until the next rotor replacement around the year 2045. Also included in this scope are new compressor stator vanes due to the compressor being 28 years old; the best way to restore the compressor to like-new condition is to replace the stationary parts when the blades are already being replaced. Lastly, the exhaust frame will be upgraded to a robust exhaust frame due to reliability issues over the years, and the rotor replacement is an appropriate time to replace the exhaust frame. For one year of operation (based on 2022 data), Zeeland Phase 2 saved Consumers Energy and customers approximately $80 million due to being less expensive than the system cost. Assuming Zeeland Phase 2 continues to be significantly valuable from 2028 through 2045, this yields significant forfeited savings that Zeeland Phase 2 could have contributed should the rotors not be replaced. Additionally, Zeeland Phase 2 has an electrical generation supply contract with Hemlock Semiconductor through 2040 that would be violated should the units become unavailable for anything but normal outage cycles. With the refurbished rotor's design life of 100,000 hours, the timing with the maintenance cycles would incur additional costs due to the 32,000-hour maintenance cycle leading to a HGPI outage at the rotor replacement requirement. As mentioned, the HGPI does not require the rotor to be pulled for inspection and parts replacement. Additionally, the total Major Outage duration for both gas turbines is approximately 55 days compared to HGPI's duration of 25 days. The rotor replacement not lining up with a Major leads to additional GE costs as the LTSA costs cover alternating between HGPIs and Majors for hours-based gas turbines like those at Zeeland Phase 2, where the rotor replacement essentially requires more work similar to a Major. Lastly, the cost of the rotor replacement to get to 2045 could not be avoided like in Alternative #2. Section 3's "Project Benefits/Objectives" box discusses the benefits in detail and the extra costs mentioned above, but a high-level summary is that potentially large savings could be forfeited compared to purchasing the generation that Zeeland Phase 2 generates on the MISO market from 2040 to 2045 if the rotor is not replaced in 2040 (disallowing continued operation). If it is determined Zeeland is needed to generate beyond 2040, the additional costs due to doing an off-cycle rotor replacement (leading to the aforementioned additional outage duration, PSCR, additional GE labor, and not avoiding this second rotor replacement) is approximately $43 million in 2028 dollars.
	Assumptions	The design life of the rotor requires it to be replaced at 144,000 hours to continue operation beyond this point. If the rotors are not replaced during the 2028 Major Outage, where they will have approximately 130,000 hours, the Major work would still be required to operate due to the 32,000-hour maintenance cycle requirement for hot parts replacement. The turbines could then run for another 14,000 hours (less than 2 years), at which point Phase 2 would have to cease operation due to meeting the design rotor life. 100% chance of Phase 2 becoming inoperable in 2029 if this work is not performed, leading to forfeiting $80M of savings when comparing purchasing Zeeland Phase 2's generation on the MISO market. Refurbishing rotor replacement alternative assumption: Assuming that Zeeland is required to generate from 2040 to 2045, using this option would require the company to spend an additional $43M in 2040 for a new rotor. Hard Benefits: Enables continued operation beyond 2028: Assumption that 2022 Zeeland Phase 2 generation savings compared to buying power from the market, worth approximately $80M, will continue to be true or greater in 2029. Avoids the below Alternative #3 additional costs totaling $43M in 2028 dollars if needed to operate to 2045, costing $17M more than the New Rotor cost in 2028: Outage Duration PSCR Costs Compared to Alternative #2's 25-day HGPI Outage required in 2040, this Rotor Replacement Outage would require 55 days (30 more days) 30 days x 24 hours x $30/MWh (assumed difference between LMPs vs. Site Cost) x 550 MW = $11.9M Additional GE Labor not Planned for under the LTSA = Assumed $3M Second Rotor Replacement = $28M Rotor Improvements: Improved damage tolerance/robustness, Reduced current inspection requirements (e.g., R0 erosion checks, Stator Vane inspections), Increased reliability and availability Improved end-of-life or extension-of-life flexibility decisions compared to Alternative #2 by the rotor design life going to Year 2045 for potential: Phasing out Zeeland Generation in the Consumers Energy portfolio, Converting the turbines to burn a different fuel, Implementation of carbon capture, Implementation of possible other technologies that have not yet emerged

Investment Name	Scenario
(12833) ZGS - Purchase of Site Spare GSU	**Draft**

Value Function	**Consumers Energy Value Function**

Zeeland Generating Station consists of four gas turbine powered plants and one steam turbine powered plant. The units transmit their power to the grid via Generator Step Up (GSU) transformers. If a GSU were to fail, then the associated turbine would not be able to transmit power and would not be able to generate energy and capacity market value for Consumers Energy and its customers. For Zeeland Phase 2 combined cycle plants, the combustion turbine requires the operation of the steam turbine, therefore the loss of the steam turbine GSU would effectively limit operation of two connected combustion turbine units. The lead time for a GSU is currently 100 weeks and spare units at other facilities typically do not exist. The site is currently projecting retirement in the 2050 timeframe. This project would purchase a spare GSU that is sized to be able to replace any of the existing transformers on site and develop redundancy for any minor power upgrades in the future

Investment Type	Generation	Planning Portfolio	Zeeland
Facility	Zeeland / Zeeland		

Executive Summary

The project involves the strategic purchase of a spare Generator Step Up (GSU) transformer for the Zeeland Generating Station. This spare GSU will be of sufficient size to replace any of the existing transformers on site, thereby eliminating the potential for a 24-month unplanned unit outage.

Objectives:

Mitigate lost generation risk of up to 540MW for a period of up to two years.
Ensure redundancy for any minor power upgrades in the future.
Mitigate the risk of prolonged outages due to GSU failure, thereby maintaining the operational integrity and reliability of the facility.
Recommended Alternative: Purchase a new spare GSU.

Draft Forecast: $4,930,694 (Between Jan 2024 and Dec 2026)

Model Assumptions:

A future failure of any of the five GSU transformers would remove the generating value of a unit, up to 280MW or more, and potentially remove it from being claimed as a resource to meet customer capacity needs. The duration of this outage would be expected to last up to 24 months.
Loss of the steam turbine GSU could result in a loss of both associated combustion turbines and a loss of up to 540MW for possibly two years.
Assume an average of 350MW for potential derate, with a 3% chance of realizing this risk.
Potential capacity losses in the event of a forced 350MW derate for two years have been calculated at $155,930,202, using a conservative calculator provided by the capacity forecast team. The CONE value used for this model is $130,930, with 75% of CONE used for the calculations as customary.

Conclusion: Purchasing a spare GSU transformer is essential to mitigate the risk of prolonged outages and ensure the reliable operation of the Zeeland Generating Station. This project aims to safeguard the facility's performance, prevent significant financial losses, and maintain the ability to meet customer capacity needs.

	EPM Managed	Yes
	Outage Type	Other
	Scope	Strategically purchase a spare transformer of sufficient size to be able to replace any of the GSUs for the site. This would eliminate the potential of a 24-month unplanned unit outage. This size is currently estimated as a 280MVA unit.
	Objectives	This project offsets the lost generation risk of up to 540MW for a period of up to two years. Calculated IRR for this project was 118%. The site currently does not have any identified spare. Recent testing on 1A GSU revealed that the OEM does not recommend placing it back into service. A separate project is being developed to overhaul the existing GSU as well as install mobile GSUs in the interim.
	Planner Recommended Alternative	Purchase a spare GSU of sufficient size to replace any of the five existing transformers which will have sufficient capability for the four combustion turbine units. Material and overhead costs to place on site is approximately $5.5M, excluding installation. Due to the criticality of these transformers and the lost cost of generation, it would be most prudent to have a site spare unit available onsite to address this risk. Zeeland Combined Cycle had an NEV for 2020 of $17.8M, and is expected even higher for 2021. Other alternative: Purchase a spare for each common transformer on site for a total of two: one for the GSU's on the combustion turbines at 225MVA, and one for the steam turbine at 280MVA. Costs for the GSU's are approximately $5.5M each (excluding installation). Total cost $11M
	Assumptions	A future failure of any of the five GSU transformers would remove the generating value of a unit, up to 280MW or more, and potentially remove it from being claimed as a resource to meet customer capacity needs. The duration of this outage would be expected up to 24 months. Loss of the steam turbine GSU could result in a loss of both associated combustion turbines and a loss of up to 540 MW for possibly two years. Assume an average of 350MW for potential derate. 3% chance of realizing this risk. This model was used twice as copperleaf can only do one year at a time. Potential Capacity losses in the event of force 350MW derate for two years have been calculated at $155,930,202 . The calculations were made using a conservative calculator provided by the capacity forecast team. The CONE value used for this model is $130,930. 75% of CONE was used for the calculations as customary. Risk was calculated from 2025 until 2040. 3% chance of realizing this risk.
Alternative Details	Purchase new spare GSU	Purchase a spare GSU of sufficient size to replace any of the five existing transformers which will have sufficient capability for the four combustion turbine units. Material and overhead costs to place on site is approximately $5.5M, excluding installation.

ZGS - Main Steam & Hot Reheat Isolation Valves Replacement	**Draft**

Value Function	**Consumers Energy Value Function**

During the Fall 2023 Steam Turbine Minor Inspection outage at the Zeeland Generating Station (ZGS), a roughly 2.5" x 0.5" piece of stellite was found in the Main Steam (MS) strainer, which is just upstream of the MS Stop/Control Valves. The only potential areas from where this stellite could have originated is either the 2A or 2B MS Non-Return Valves (NRVs) or the 2A or 2B MS Stop Isolation Valves. The MS NRVs were already planned for replacement for other reliability reasons during the Fall 2024 Outage, which was complete. When the valves were removed from 2A and 2B, they were inspected to find no evidence of failure of the stellite seat and trim. That leaves the origination of the stellite piece found in the Fall 2023 Outage as coming from the 2A or 2B MS Stop Isolation Valves. Upon further investigation, numerous valve vendors confirmed that the industry has seen many failures of stellite delaminating from a valve body's parent metal to be sent to the downstream Stop/Control Valves. The strainer should catch these potential pieces, but in at least one case in the power industry, a piece wore a hole through the strainer, sending it to the Steam Turbine path causing significant Domestic Object Damage (DOD), requiring immediate shutdown and lengthy repairs for that unit.

Investment Type	Generation	Planning Portfolio	Zeeland
Facility	Zeeland / Zeeland		

Executive Summary	The ZGS - Main Steam & Hot Reheat Isolation Valves Replacement project aims to replace the MS Stop and HR Isolation Valves at the Zeeland Generating Station (ZGS). During the Fall 2023 Steam Turbine Minor Inspection outage, a piece of stellite was found in the Main Steam (MS) strainer, indicating potential delamination from the MS Stop Isolation Valves. This delamination poses a risk of significant Domestic Object Damage (DOD) to the Steam Turbine, requiring immediate shutdown and lengthy repairs. The replacement project will ensure that no hard-faced material liberates due to delamination, as the new valves will be installed with proper Electric Power Research Institute (EPRI) techniques or better hard-facing materials. Objectives Mitigate forced shutdown risk due to stellite delamination. Ensure the new valves' hard-facing material bonds properly with the parent metal, preventing future delamination. Reduce significant costs and forced outage time due to Steam Turbine DOD. Alternatives Recommended: Replace MS Stop & HR Isolation Valves Details: Ensures no hard-faced material liberates due to delamination, using proper EPRI techniques or better hard-facing materials. Other Alternatives: Replace Only MS Stop Isolation Valves: Mitigates potential liberation from MS valves but not from RH valves. Costs about $1M less for materials and half of the previous labor estimate. Remove Stellite and Re-apply with EPRI Techniques (All Four Valves): Ensures no hard-faced material liberates due to delamination, but mixed results in the industry and difficult labor make this a non-viable option. No material cost, but labor cost is about twice the previous estimate ($2.6M). Model Assumptions Failure Impact: Forced outage of 550 MW, with a minimum 3-month derate. Significant savings if failure causes emergent repairs, as planned repairs would cost around $1M in MM compared to emergent repairs. Potential Capacity Losses: Calculated at $21,876,800 in the event of a forced shutdown. Three-year impact on capacity revenue included. CONE value used is $130,930, with 75% of CONE used for calculations. 10% chance of realizing this risk.

Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 3
	Rate Case Mapping	Gas Generation
	EPM Managed	Yes
	Outage Type	Unit - Plant
	Scope	Replace MS Stop & HR Isolation Valves This would ensure that no hard-faced material would liberate due to delamination as the new valves hard-facing would be installed with proper EPRI techniques or with a better hard-facing material that is proven to bond properly with the parent metal.
	Objectives	mitigate forced shutdown risk The Electric Power Research Institute (EPRI) has been following the stellite delamination failures and has helped develop a (costly) repair technique. Some valve vendors have developed better bonding methods of other hard-faced materials to parent metal, either equaling or exceeding the effectiveness of the EPRI-developed stellite repair methods. Specific to the ZGS 2A & 2B units, the industry has seen greater failure rates of stellite delamination in sliding parallel gate valves, which is same design of the 2A & 2B MS Stop Isolation Valves and 2A & 2B Hot Reheat (HR) Isolation Valves at ZGS. The steam path past the MS Stop Isolation Valves goes directly to the High Pressure (HP) Steam Turbine section, and the steam path past the HR Isolation Valves goes directly to the Intermediate Pressure (IP) then to the Low Pressure (LP) Steam Turbine sections. This replacement project plans to mitigate any future stellite liberations from the 2A & 2B MS Stop Isolation Valves and 2A & 2B Hot Reheat (HR) Isolation Valves, thereby mitigating significant costs and forced outage time due to Steam Turbine DOD.
	Planner Recommended Alternative	Replace MS Stop & HR Isolation Valves This would ensure that no hard-faced material would liberate due to delamination as the new valves hard-facing would be installed with proper EPRI techniques or with a better hard-facing material that is proven to bond properly with the parent metal. other alternatives: Replace Only MS Stop Isolation Valves This would mitigate the potential for the MS valves to have no further liberation (from where ZGS has seen liberation before). However, this would not mitigate the same failure potential from the RH valves which are the same design and susceptible to the same failure. This would cost about $1M less for materials and about half of the previous labor estimate. Remove stellite and re-apply with techniques from EPRI (all four valves): This should ensure that no hard-faced material would liberate due to delamination. However, there are mixed results in the industry for the effectiveness of the EPRI installation technique. The labor to do this with the valves in place may also prove to be difficult or almost impossible, making this a non-viable option. This would have no material cost and would cost about twice of the previous labor estimate. ($2.6M)

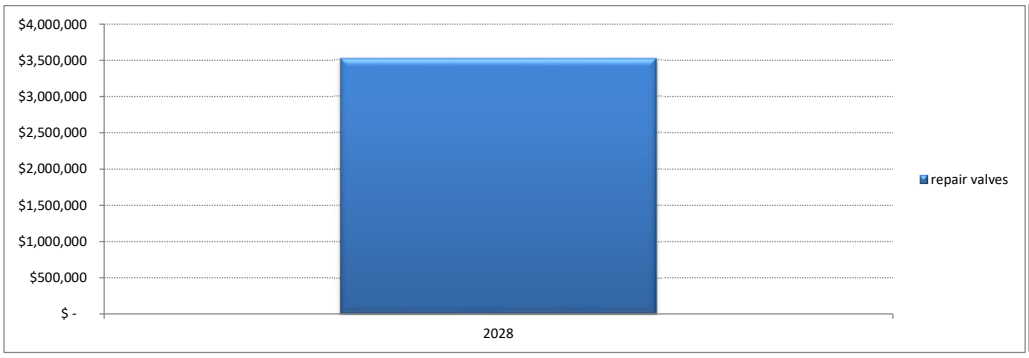
Investment Name	Scenario
ZGS - Main Steam & Hot Reheat Isolation Valves Replacement	**Draft**



Value Function	**Consumers Energy Value Function**

	Assumptions	If failure were to occur today: forced outage of 550 MW (all of Phase 2 would shut down due to Steam Turbine being inoperable). A 3-month derate would be the minimum – Valves repairs would likely be less than three months but depending on the Steam Turbine damage and parts availability three months may be too short. significant MM savings should a failure cause emergent repairs as to repair all four valves would cost around $1M in MM compared to planning ahead and that $1M being Capital (plus the cost of four new valves) with no Steam Turbine MM repairs (which would not be covered by the GE LTSA either). Steam Turbine DOD worth a minimum of $10M if MS Valves not replaced or minimum of $15M if the HR Valves not replaced in addition to $500k in valve repairs (for two valves, $500k more for the other two valves). A probability number is difficult to determine, but ZGS did catch a large piece of stellite in the MS strainer, as discovered in Fall 2023, and ZGS has four valves on which additional stellite liberation could occur, which could (in theory, and as has happened at least one time in the power industry) wear through a strainer to cause DOD to the Steam Turbine. 10% chance. Potential Capacity losses in the event of forced shutdown have been calculated at $21,876,800. The calculations were made using a conservative calculator provided by the capacity forecast team. Three-year impact on Capacity revenue is included in this number. The CONE value used for this model is $130,930. 75% of CONE was used for the calculations as customary. 10% chance of realizing this risk.

GEN002363	**2026**	**16**	**Literal**

Investment Name	Scenario
ZGS - ST 2C Field Exchange and Generator Major Overhaul	**Draft**

Value Function	**Consumers Energy Value Function**

In power generation, a generator converts the mechanical energy of the associated turbine (steam/gas) to electrical energy, which is then transmitted to the grid through generator step-up transformers (GSU). The generator consists of two major components: a generator stator and a generator field/rotor. The field/rotor has a DC current applied to it to produce a DC magnetic field and is coupled to a prime mover (in this case, a steam turbine) that supplies rotational energy to the rotor, creating a rotating magnetic field. This rotating magnetic field induces voltage onto the 3-phase stator winding, which is then carried out through bushings to the GSU, where this voltage is stepped up to transmission level voltages.

Investment Type	Generation	Planning Portfolio	Zeeland
Facility	Zeeland / Zeeland		

Executive Summary	Problem Statement: Per the latest flux probe test conducted by GE in 2023, it is estimated that the generator field has at least one shorted turn. A shorted turn typically develops from dust/debris accumulated at turn-turn insulation or deteriorated field winding insulation. This adds electrical and mechanical stress to the machine, increasing generator rotor vibrations and heat dissipation. In the long term, the generator could continue to deteriorate, resulting in several shorted turns, at which point the field may not be able to build the required voltage to maintain generator terminal voltage and MVA. It is expected that the number of shorted turns will increase by 2028, and a field rewind/replacement is recommended. Several areas of dusting were identified in the generator stator during the borescope inspection in 2023. Moderate amounts of iron oxide dust were noted on the stator core and end winding axial supports. Oil leaks in the generator may eventually combine with the dust and form grease, which has low dielectric strength and may risk an internal flashover in the generator stator. During the minor outage of 2023, excessive grooving on the collector ring's brush riding surface was noted. Grooving leads to excessive brush wear and increased maintenance cost. GE recommends replacing the collector ring during the 2028 outage. Planner Recommended Alternative: Field exchange and generator major overhaul, including belly band tightening, core bolt tightening, and re-wedge of the generator stator. This work will require engineering and erecting a platform to pull out, store, and load the rotor on a truck. Other Alternatives Considered: Continue inspection and testing the generator during every minor and major outage. This is covered by the LTSA agreement and will incur no additional cost to Consumers Energy. However, this will not address the issue with shorted turns found in the field or any other issues noticed in the stator during the borescope inspection, which may lead to a forced outage on phase 2. The cost is reflective of the project-associated scope at a later year and may be much higher in the event of a forced outage on the steam turbine generator. Model Assumptions: Doing nothing may result in a catastrophic failure of the generator and a forced outage for at least two months. The probability of system failure without maintenance intervention is estimated at around 20-30% over the next few years, translating to about a 5% probability of failure each year. Potential capacity losses in the event of forced shutdown have been calculated at $12,604,129, based on a conservative model using 75% of the CONE value ($130,930). A 3% probability of realizing this risk was assumed given the copperleaf software constraints.

Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 3
	Rate Case Mapping	Gas Generation
	EPM Managed	Yes
	Outage Type	Unit - Plant
	Scope	Design and construct a platform to pull out the generator rotor. Generator field exchange. Belly band tightening. Core bolt tightening. Re-wedge.
	Objectives	Mitigate forced shutdown risk Detailed benefits: Shorted Turns in the Generator Field: The presence of at least one shorted turn, as identified in the 2023 flux probe test, indicates existing electrical and mechanical stress. If left unaddressed, the number of shorted turns is expected to increase, leading to higher vibrations and heat dissipation. This could eventually prevent the generator from maintaining terminal voltage and MVA. Dust and Debris Accumulation: The presence of iron oxide dust and oil leaks forming grease with low dielectric strength poses a risk of internal flashover in the generator stator. This condition, if not rectified, can lead to significant damage and potential failure. Collector Ring Wear: Excessive grooving on the collector ring's brush riding surface can lead to increased maintenance costs and potential failure of the DC field energizing system. This issue, if not addressed, can cause operational disruptions.
	Planner Recommended Alternative	Field Exchange and Generator Major Overhaul. Other alternatives considered: Continue inspection and testing the generator every minor and major outage. This is covered by the LTSA agreement and will incur no additional cost to Consumers Energy. However, this will not address the issue with shorted turns found in the field or any other issues noticed in the stator during the borescope inspection, which may lead to a forced outage on phase 2. The cost is reflective of the project-associated scope at a later year and may be much higher in the event of a forced outage on the steam turbine generator.

ZGS - ST 2C Field Exchange and Generator Major Overhaul	**Draft**

Value Function	**Consumers Energy Value Function**

	Assumptions	Doing nothing may result in a catastrophic failure of the generator and a forced outage for at least 2 months. Based on the provided text and general knowledge about generators at large gas plants, the probability of system failure if no maintenance is performed can be significant. Justification is as follows: Given these factors, the probability of system failure without any maintenance intervention is relatively high. The exact probability can vary but based on industry standards and the specific issues identified, it could be estimated at around 20-30% over the next few years. This estimate considers the cumulative impact of multiple failure points and the critical nature of the identified issues. To translate this into a yearly probability, we can use the concept of the annual failure rate (AFR). Assuming a 25% probability of failure over 5 years, there is about a 5% probability of failure each year. probability escalates to 10% on average from 2030 until 2040. Potential Capacity losses in the event of force shutdown have been calculated at $12,604,129. The calculations were made using a conservative calculator provided by the capacity forecast team. The CONE value used for this model is $130,930. 75% of CONE was used for the calculations as customary. 3% probability of realizing this risk was assumed as there is no way to enter 5% on the financial risk model.
Alternative Details	Field exchange and Generator stator repair	Field exchange and Generator stator repair.
	Continue inspection and testing the generator every minor and major outage	This is covered by the LTSA agreement and will incur no additional cost to Consumers Energy. Investment Name	Scenario
JGS - Generator Step Up Transformer (GSU) Site Spare	**Draft**

Value Function	**Consumers Energy Value Function**

The Jackson Generating Station (JGS) relies on its main Generator Step-Up (GSU) transformers to transmit power generated from its units to the grid. These GSUs are a single point of failure, meaning that a failure of any GSU could result in a significant loss of power generation. Depending on the unit affected, the potential generation loss could range from 47 MW to 104 MW. This presents a substantial operational risk, as the lead time for procuring a new GSU is around 3 years. This extended lead time is primarily because each transformer of this size is custom-built, requiring specialized raw materials and engineering, much like the Covert GSU project. Given the significant derate risk, any GSU failure would cause an extended derate, during which replacement procurement would be highly delayed.
Based on the current assessment of the existing generator start-up transformer, the probability of failure is currently estimated at 5%. This probability is projected to escalate by 5% annually. Given that the industry life expectancy for GSU transformers of this vintage is approximately 20 years, and these units have already reached that timeframe, the risk of failure is increasingly likely. As the GSUs age beyond their expected lifespan, the likelihood of failure grows, raising concerns about both operational reliability and financial impacts.
While Consumers Energy has spare transformers at other sites, such as Campbell, Karn, Lake Winds, and Crosswinds, none of these spares are compatible with the specific voltage requirements (138kV-13.2kV-13.2kV) or winding configuration (WYE-DELTA) needed at JGS. To address this in the short term, an O&M-funded project aimed to secure a spare GSU sharing and leasing agreement with Midland Cogeneration Venture (MCV) to cover a potential transformer failure at JGS. However, the failure to reach an agreement with MCV in 2024 has left JGS without an immediate backup solution, escalating the risk of prolonged derates.

Investment Type	Generation	Planning Portfolio	Jackson
Facility	Jackson / Jackson		
Executive Summary	The Jackson Generating Station (JGS) relies on its main Generator Step-Up (GSU) transformers to transmit power from its generating units to the grid. These GSUs represent a single point of failure: a loss of any GSU would immediately force a significant derate and disrupt operations. Procurement of a replacement GSU requires custom engineering and specialized materials, resulting in lead times of approximately three years, which exposes JGS to prolonged operational and financial risk. Existing spare transformers at other Consumers Energy sites (Campbell, Karn, Lake Winds, Crosswinds) are not compatible with JGS's voltage (138 kV–13.2 kV–13.2 kV) and winding configuration (WYE–DELTA). Previous efforts to secure a lease agreement with Midland Cogeneration Venture (MCV) failed in 2024, leaving JGS without a viable short-term backup solution. This reinforces the need for a dedicated on-site spare GSU to mitigate extended derate risk. Updated Modeling Approach (Copperleaf): • Derate Magnitude: 104 MW (planning basis), reflecting both LMs offline for an LM-tied GSU failure. Sensitivity ranges: ~90 MW (STG), 131–135 MW (LM), 136–145 MW (7EA). • Restoration Window: ~1,080 days (≈3 years) for procurement and commissioning. • Copperleaf Limitation: Lost Generation Risk module caps outage duration at 365 days, making energy-loss valuation conservative versus the true exposure. The Financial Risk leg still reflects full multi-year capacity impacts. • Probability Curve: 5% in 2026, increasing by 5 percentage points annually through December 2039. • Capacity Value: $28 million exposure for a 104 MW, 1,080-day derate based on MISO's rolling 3-year ZRC accreditation methodology and 75% CONE ($127,135). • Energy Value: Uses historical and forecasted capacity factors from the current PSCR case, incorporating NOx/CO limits and the site's "adder" operating practice. Copperleaf Risk and Investment Outputs (NPV in $000): • Financial Risk (Capacity Revenue Loss): 9,599 • Lost Generation Risk (104 MW Derate): 6,774 • Total Investment Cost (Spare GSU): -4,423 • Total Value: 11,951 Recommended Alternative: Purchase and store a spare GSU on-site at JGS • Estimated cost: $5 million (includes transformer and storage pad). • Benefits: Immediate access to a compatible spare, elimination of dependency on external agreements, mitigation of prolonged derate risk, and alignment with Copperleaf-based risk-adjusted valuation. Other Alternative Considered: Lease a Spare Transformer and Overhaul Failed GSU • Estimated cost: $10.8 million plus ongoing rental fees. • Limitation: No rental units meet JGS's voltage and winding specifications; prior MCV lease attempt failed.

Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 3
	Rate Case Mapping	Gas Generation
	EPM Managed	Yes
	Outage Type	Unit - Plant
	Scope	Create bid specification for design of a spare Jackson Generating Station Main Generator Step Up Transformer (GSU) Create specification for the JGS spare GSU storage area (foundation and power if needed) Bid out and procure spare JGS GSU Provide onsite quality oversight of manufacturing at the facility. Bid out and install spare GSU storage area in time for receipt of the spare GSU.
	Objectives	This project provides JGS with a reliable spare GSU it currently does not have access to. In parallel with this project, CE is entering a shared spare lease agreement with Midland CoGeneration (MCV) in the 3rd or 4th quarter of 2023 via O&M funding to provide immediate short-term availability of a spare GSU for the site if needed. However, this agreement does have terms and conditions such that MCV can reject our request to use their spare GSU should they be in need of the spare or intend to use otherwise at their discretion, which is not a reliable plan for long term reliability for our customers. This will also mitigate the need to continue to carry the MCV lease agreement O&M expense ($60K/yr) once this spare GSU is close to delivery at site, saving future O&M spend on this agreement through the remaining life of the plant.

Investment Name	Scenario
JGS - Generator Step Up Transformer (GSU) Site Spare	**Draft**

Value Function	**Consumers Energy Value Function**

	Planner Recommended Alternative	Purchase new spare GSU transformer This option involves the procurement and long-term storage of a spare Generator Step-Up (GSU) transformer at the Jackson Generating Station (JGS). The estimated cost for this approach is $5 million, which includes the purchase of the spare GSU and the installation of a dedicated storage area or pad to ensure its safe preservation until needed. Rationale for Selection Purchasing and storing a spare GSU on-site at JGS is the most cost-effective, predictable, and reliable long-term strategy to mitigate potential losses and operational disruptions in the event of a GSU failure or overhaul. This solution provides JGS with a dedicated spare transformer that is immediately accessible when required, ensuring minimal downtime and avoiding costly delays associated with the procurement of a replacement unit. Other alternative considered: Lease a Spare Transformer, Overhaul the Failed GSU (If Repairable) This option examines the viability of leasing a GSU transformer. It entails obtaining and installing a rental GSU transformer if there is a failure, while the faulty GSU is dispatched for repairs, assuming it can be overhauled. This approach is estimated to cost approximately $10.8 million, based on similar scope projects, including the Zeeland Generating Station. The breakdown of costs includes $400,000 per month for the rental unit ($4.8 million per year), $3 million to overhaul the failed GSU if repairable within a one-year timeframe and an additional $3 million to remove, transport and install both the rental unit and the failed GSU. There are significant limitations to this option, primarily stemming from the unavailability of rental transformers with the specific voltage requirements (138kV-13.2kV-13.2kV) and winding configuration (WYE-DELTA) necessary for JGS. This means that leasing a spare GSU is not currently viable, as no rental units meet the unique specifications required for JGS operations.
	Assumptions	Technical failure mode: • Transformer configuration: Each LM GSU has one high-side connection and two low-side connections (one per LM). Practical isolation of a single LM on a failed GSU is not possible; both LMs tied to that GSU must be removed from service. • Planning basis: Maintain 104 MW derate for modeling consistency and technical accuracy (reflects both LMs offline for an LM-tied GSU failure). Sensitivity bands: ~90 MW (STG GSU), 131–135 MW (LM GSU), 136–145 MW (7EA GSU). • Restoration window: True economic exposure aligns with ~1,080 days (≈3 years) for procure/replace/commission. Copperleaf limitation (important conservatism): • Copperleaf Lost Generation Risk model allows a maximum outage duration of 365 days. We therefore enter 365 days in that module; this UNDERSTATES total energy loss vs. the true ~1,080-day exposure and is conservative. The Financial Risk (capacity) leg still reflects the full multi-year accreditation impact as described below. Probability of occurrence (annual schedule used in both risk legs): • 2026: 5%; 2027: 10%; 2028: 15%; then +5 percentage points per year through December 2039. Event treated as single-event loss applied in the year realized; probabilities apply only while no spare is in place. Capacity value methodology (Financial Risk leg): • Accreditation rule: MISO rolling 3-year average of ZRCs; any forced outage >30 days reduces accredited capacity for multiple subsequent years. • CONE basis: 75% of CONE = $127,135 (planning anchor). • Reference exposure: $28 million capacity value impact for a 104 MW, 1,080-day derate using the rolling ZRC methodology (used as the capacity consequence and then probability-weighted). • Market offer assumption: Unit not offered into the capacity market during extended derate; we quantify foregone capacity value only (no replacement capacity purchases). Energy (NEV) methodology (Lost Generation Risk leg): • Dispatch & capacity factor inputs: Use historical and forecast CF from the current PSCR case (not unconstrained Aurora). This corrects the earlier overstatement and aligns with portfolio standards. • Emissions constraints: Incorporate Jackson's NOx/CO limits and the site "adder" operating practice (weekly monitoring/offer adjustments) when shaping run-hours and margins. • Engine stall risk: Modeled as a separate operational risk (own probability and consequence) to avoid double counting. Lead time & alternatives:

Investment Name	Scenario
JGS - LM1-6 VIGV(variable inlet guide vane) Project	**Draft**

Value Function	**Consumers Energy Value Function**

The gas turbines at Jackson Generating Station currently use fixed Inlet Guide Vanes (IGVs) that limit their ability to adapt to varying operating conditions. This results in suboptimal performance, reduced efficiency, and increased risks to turbine reliability. The following are the key challenges associated with the current system:
•Inefficiency of Fixed IGVs: The fixed angle of the IGVs restricts airflow modulation, preventing the turbines from operating at peak efficiency across different ambient conditions and power settings. This leads to inefficient fuel use, particularly at part load, which is common in load-following operations at Jackson Generating Station.
•Fuel Consumption and Heat Rate: Due to the inability of the current system to adjust for optimal airflow, the heat rate of the turbines is higher than necessary, which increases fuel consumption. The inefficiency becomes more pronounced during partial load conditions, where fuel savings are critical for economic operation.
•Increased Risk of Engine Stall: Without dynamic control of the IGV angles, the turbines are more susceptible to engine stalls during rapid power reductions or operational fluctuations. An engine stall can cause significant damage to the turbines, resulting in costly repairs and extended downtime.
•Dependence on Duct Firing: To meet power demands, the station relies on duct firing, which is less efficient, consumes more fuel, and places additional stress on the system. This dependency results in higher operational costs and increased emissions.

Investment Type	Generation	Planning Portfolio	Jackson
Facility	Jackson / Jackson		

Executive Summary	Jackson Generating Station plans to upgrade six LM6000PC units (LM1–LM6) from fixed to Variable Inlet Guide Vanes (VIGV) to improve efficiency, reliability, and dispatch flexibility under NOx-constrained capacity factors. Fixed IGVs limit airflow modulation, driving inefficient fuel use at part load, elevated heat rate, higher stall risk during rapid load changes, and reliance on less efficient duct firing. The VIGV system enables dynamic airflow control, increasing base-load capability and reducing duct firing without changing the site's ~560 MW (net) maximum output. Expected uplift is ~+12 MW at the gas turbines plus ~+15 MW at the steam turbine from increased exhaust energy, for a site-wide base-load increase of ~+27 MW. Heat rate improves by ~189 Btu/kWh at baseload (no duct); baseload HR improves from ~7,951 to ~7,762 Btu/kWh (LHV, no duct). Efficiency gains persist across the load range (≈2% at ~70% load). The upgrade increases stall margin, lowering the likelihood of damaging stall events during load-following and reducing unplanned downtime. Generation Shift: +12 MW gas turbine base load plus +15 MW steam from increased exhaust energy → ~+27 MW site-wide base-load capability. Site maximum remains ~560 MW (net), but generation shifts from duct firing to efficient base load. Fuel Efficiency: Heat rate improves by ~189 Btu/kWh at baseload (no duct). Baseload HR drops from ~7,951 to ~7,762 Btu/kWh (LHV, no duct). Efficiency gains persist across the load range (~2% at ~70% load). Reliability: Increased stall margin reduces risk of catastrophic stalls and unplanned outages. Model Assumptions Six LM6000PC units; heat-rate values on LHV basis.NOx-driven capacity factor limits incorporated using historical performance. Stall risk: ~1 event every 5 years; repair cost up to $7.4M per turbine. Copperleaf planning uses 10% probability and $5–$15M consequence range → ~$22.2M cumulative risk avoided over 15 years. Each stall causes ~90 MW derate for ~3 weeks (loaner engine install/remove included). Economic Impact Economic valuation has been revised from the initial Aurora run to a Copperleaf-based approach that (1) incorporates NOx-driven capacity factor limitations using historical performance and (2) explicitly prices stall risk and derate impacts. Value streams include fuel savings from lower heat rate, incremental base-load generation (with reduced duct firing), and avoided stall repairs and derate losses. A single stall can cost up to $7.4M per turbine (updated from $4M based on a recent LM306 engine stall event), with an underlying expectation of ~1 event every 5 years (~20% per five-year period). For planning within Copperleaf (tooling constraint), a conservative 10% probability with a $5–$15M consequence range is used, yielding an estimated cumulative consequence of ~$22.2M over 15 years that the VIGV upgrade helps mitigate. Each stall also drives an unplanned ~90 MW derate for ~3 weeks (≈1.5 weeks to install a loaner engine and ≈1.5 weeks to remove it post-repair). Financial Analysis Total Value of $11.035M in overall benefits from the VIGV upgrade, derived from: Fuel Savings: $8,188K,Financial Risk (stall avoidance): $5,300K, Lost Generation Risk: $133K, Total Investment Cost: –$2,587K Total value: $11,035K

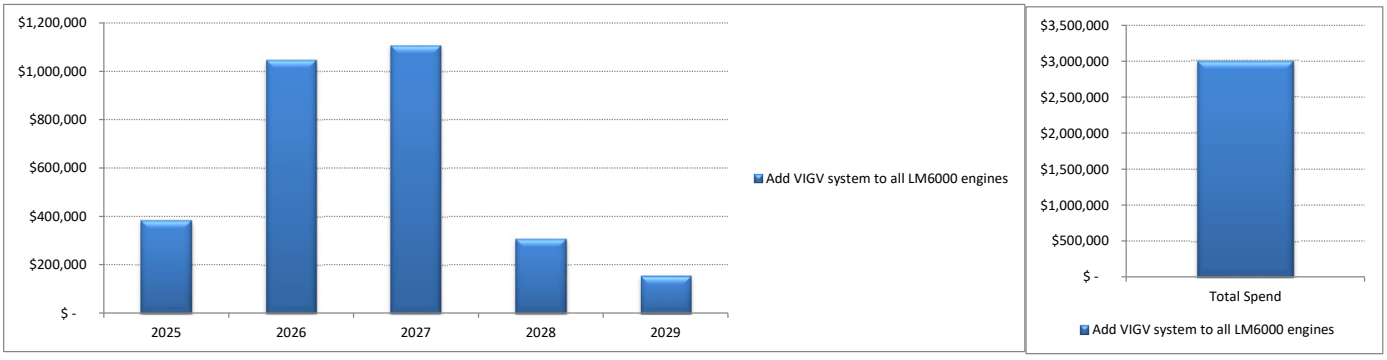
Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 3
	Rate Case Mapping	Gas Generation
	EPM Managed	Yes
	Outage Type	Unit - Plant
	Scope	Install VIGV system on Engine Serial Number (ESN) 185-132 during its normally planned Major Overhaul interval April 2025 Install VIGV system on six other engines during their normally planned hot section interval: September 2025: ESN 191-312 April 2026: ESN 191-339 September 2026: ESN 191-307 April 2027: ESN 191-345 September 2027: ESN 191-306 April 2028: ESN 191-351
	Objectives	This upgrade will: •Increase Base Load Output: The VIGV system will enhance the base load capacity of the gas turbines by 12 MW and contribute to a total site-wide increase of 27 MW when combined with steam turbine improvements. This increase will reduce the reliance on inefficient duct firing. •Improve Fuel Efficiency: The upgrade will improve the baseload heat rate by approximately 189 Btu/kWh (without duct firing) and 286 Btu/kWh (with duct firing). •Enhance Stall Margin: By allowing better airflow control, the VIGV system will improve the stall margin, reducing the risk of turbine failure during rapid load changes and ensuring more reliable operation. This project is critical for improving the overall performance and efficiency of the turbines, reducing operational costs, and minimizing the risk of unplanned outages due to engine stalls.
	Planner Recommended Alternative	Install VIGV upgrade.

Concept Approval Internal Report

Investment Code	Report Start Year	Number of Years	Currency Scale
GEN002192	2025	5	Literal

Investment Name	Scenario
JGS - LM1-6 VIGV(variable inlet guide vane) Project	Draft



Value Function	Consumers Energy Value Function

	Assumptions	Revised economic modeling: The initial Aurora model did not account for the capacity factor limitation at the Jackson station from NOx emission limitations. Also, the engine stall risk was not included in this model. In order to accurately quantify the risk of the stalls and incorporate the accurate forecasted capacity factors based on historical performance, the approach to the value modeling was changed to a Copperleaf based approach. This will also align the business case with current practice post-adoption to the use of Copperleaf for business case generation. Fuel Efficiency Improvement Without the upgrade, the station will continue to operate with a heat rate of 7,951 Btu/kWh (LHV, assuming no duct burners used) for each LM6000PC turbine during base load operations. The VIGV upgrade would have reduced this heat rate to 7,7614 Btu/kWh (LHV, no duct burners used), leading to more efficient fuel usage and cost savings (heat rate improvement of 189 Btu/kWh across the entire load range). Refer to table in original concept approval for a summary of the increase in generation and heat rate impacts with and without VIGV. By not upgrading, the plant misses a significant MW improvement in output at lower heat rates without duct burners, and a considerable heat rate improvement of 189 Btu/kWh across the entire load range. This represents a significant loss in fuel savings and operational efficiency over time. Risk of stall event: $7.4M repair costs from stalls. expect to have a stall every 5 years. Three stalls over the next 15 years. $22.2M total risk. Stall Risk: The existing fixed IGV system increases the risk of engine stalls, particularly during rapid load reductions. An engine stall is a critical failure that can lead to catastrophic damage, requiring costly repairs. The estimated cost of an engine stall repair is up to $7.4 million per turbine (number updated from $4M based on recent 306 engine stall event updated costs), with an average stall probability of one occurrence every five years (20%). Due to Copperleaf software limitations a conservative probability of 10% with a consequence of $5M-$15M will be used for planning purposes. Over the next 15 years, the overall consequence is estimated at $22.2 million in repair costs that will be mitigated by the VIGV system. The stall events also result in a 90MW unplanned derate for a total of three weeks. It takes about 1.5 weeks for the loaner replacement engine to be delivered and installed and then another 1.5 weeks to uninstall once the repairs are completed on the failed engine. A 20% probability of realizing this risk every 5 years will be assumed for planning purposed.
Alternative Details	Add VIGV system to all LM6000 engines	Per Unit (x6): 2 MW output gain without duct firing, greater than 2% fuel efficiency gain at part load, exhaust energy increase of 3%, and greater protection from an engine stall condition. (Assumptions: $575K for 6 engines + $150K for 1 engine. Cost estimates include hardware, software, engineering, and labor for installation plus loadings.)

Investment Name	Scenario
JGS Unit 7 Gas Turbine Rotor Replacement	**Draft**

Value Function	**Consumers Energy Value Function**

The rotor for a GE 7EA gas turbine has a life limit of either 5000 starts or 250,000 running hours. JGS Unit 7 (GE 7EA GT) gas turbine rotor is expected to hit its limit for starts before hitting its limit for running hours in the year 2032. JGS Unit 7 has planned maintenance intervals, either major overhaul or hot gas path, approximately every 5 years. The next major overhaul is tentatively in 2028 and the next hot gas path tentatively 2034. Based on the running profile of JGS, the unit will not be allowed to operate with the current rotor until 2034, and it would be unwise to take an additional outage between 2029 & 2034 to replace the rotor when it can be done in 2028.

Investment Type	Generation	Planning Portfolio	Jackson
Facility	Jackson / Jackson		

Executive Summary

The Jackson Generating Station Unit 7 Gas Turbine Rotor Replacement project is a critical initiative to ensure long-term reliability and efficiency of the GE 7EA gas turbine. Recent operational changes and updated forecasts have shifted the preferred strategy for rotor replacement.
Key Updates

Unit 7 Operational Change:

Expected to run as a baseload unit starting in 2026, significantly increasing operating hours compared to current cycling operations.
If Unit 7 operates as baseload and is separated as its own node, a refurbished rotor will not have sufficient hours to last until 2041.
Continuing current operations would allow a refurbished rotor to meet the 2041 target, but this scenario is no longer expected.

Rotor Replacement Options
New 7EA Rotor: Provides 5,000 starts / 128,000 operating hours.
Ensures turbine life through 2041 under baseload conditions.

Refurbished 7EA Rotor: Provides 4,500 starts / 95,000 operating hours.
Insufficient for 2041 if baseload operation begins in 2026.

Preferred Option: Install a new rotor. This approach avoids additional outages and ensures compliance with the new operating profile. Estimated cost: $3,622,500 .

Refurbished Rotor Alternative: Estimated cost: $2,976,102.
Would require additional outage and replacement before 2041, increasing total lifecycle costs.

Savings Assumption: Approximately $2.8M in avoided costs when factoring inflation, additional outage time, and resource requirements for a second replacement.

Rotor life limit: 5,000 starts or 250,000 hours.
Current rotor expected to reach start limit by 2032, before hour limit.
Replacing during 2028 major overhaul prevents an extra 40-day outage and mitigates high failure risk after 2032.

Recommendation: Proceed with new rotor replacement during the 2028 major overhaul to align with baseload operation plans, minimize lifecycle costs, and ensure reliable operation through 2041.

Last Approver	Thompson, Cornelius (CORNELIUS.THOMPSONJR@CMSENERGY.COM)	Approval Date	1/7/2025

Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 3
	Rate Case Mapping	Gas Generation
	EPM Managed	Yes
	Outage Type	Major Equipment
	Scope	Replace the rotor with new. GE engineering, as part of product design, determined what the finite operating life of the 7EA class rotor. This determination is based on the design, the materials used in the design, material degradation, and low-cycle fatigue from the thermal cycling associated with frequent starts and stops.
	Objectives	Mitigate forced outage risk and maximize savings by optimizing execution timing.
	Planner Recommended Alternative	Replace in 2028, avoid another potential 40-day unit outage in-between cycles, reset rotor life. A refurbished rotor typically costs 50% of a new rotor. There are some refurbished rotors on hand versus the 12–14-month lead time minimum for a new rotor. The 95,000 hours operating life of a refurbished rotor. The lifespan of the refurbished rotor could be longer if the unit becomes a baseload unit instead of a peaking unit. Other alternatives: Replace rotor in 2032: Additional costs incurred Replace with new: costs twice the price, only get 11% more starts and 35% more hours. Does not make sense for our unit at this time.

Concept Approval Internal Report

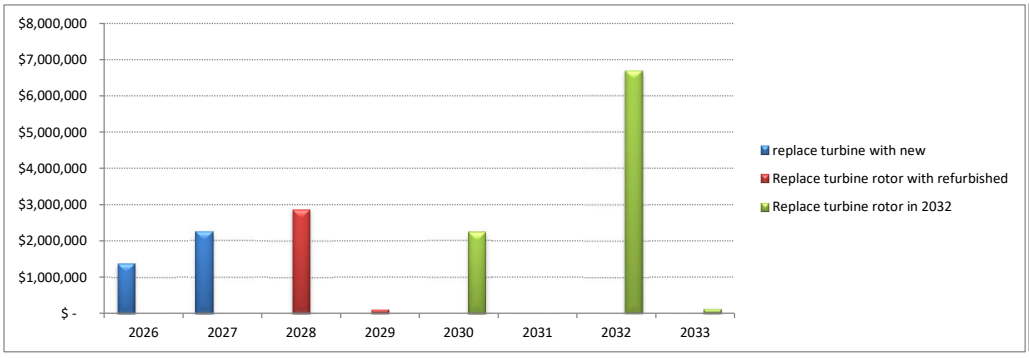
GEN002684	2026	8	Literal

Investment Name	Scenario
JGS Unit 7 Gas Turbine Rotor Replacement	Draft



Value Function	Consumers Energy Value Function

	Assumptions	A new rotor can take up to 14 months to be delivered after order. this would cause a 135-140 MW derate for the site for as long as it takes to get a new rotor. 30% probability of realizing this risk based on uncertainties around new rotor deliveries. This is a conservative estimate. Replacement rotor up to 14 months lead time with a planned order. could be longer if unexpected failure or not planned. Rotor failure could happen any time after reaching rotor life limit. This will be considered high probability after 2032. Replace turbine rotor in 2032 will require an additional Major outage to complete the project. This will incur major costs as the entire plant would have to be shut down for around 4 weeks. 100% probability of realizing this risk if selecting this option. The cost of the risk was calculated using the lost generation risk model and used in this model as an added cost in 2032. The calculated cost is $6,891,000. Unit 7 is expected to be ran as a baseload unit starting sometime 2026. If Unit 7 is separated out as its own node to run baseload, then a refurbished rotor will not have enough hours to make it to 2041. Whereas if the plant continues to operate as is, then a refurbished rotor would have enough hours to make it to 2041. Rotor replacement with a new 7EA rotor. Expected to provide the site with 5,000 starts/128,000 hours of operation Rotor replacement with a refurbished 7EA rotor. Expected to provide the site with 4,500 starts/95,000 hours of operation Installing a new rotor vs a refurbished unit will ensure that the turbine lasts until 2041 considering that unit 7 is now expected to run as a baseload unit which means operating hours will be much higher than current operations. It will be assumed a savings of $2.8M based on current price of $2.1M for a refurbished unit plus inflation costs and additional outage time and resources to execute this project (conservative estimate).
Alternative Details	Replace turbine rotor with refurbished	Rotor replacement with a refurbished 7EA rotor during 2029 major outage ($2.4M Unloaded). Expected to provide the site with 4,500 starts/95,000 hours of operation
	Replace turbine rotor in 2032	Replace turbine rotor in 2032 will require an additional Major outage to complete the project. This will incur major costs as the entire plant would have to be shut down for around 4 weeks.
Alternative Details	replace turbine with new	With there being a possibility of the unit becoming baseload, we didn't want the rotor's life being a factor in derating the plant's output as it gets closer to 2041. We agreed to conservatively go with a new rotor over the refurbished rotor that was in CA and LTFP. This changes the project's (GEN002684/ B-PP-00260) cashflow from needing no money until 2027 to needing funds in 2026 as well as different amounts of money being needed in 2027 and 2028.

Alternative Spend Profile

Investment Name	Scenario
JGS - Main and Aux Cooling Tower Rebuilds	**Draft**

Value Function	**Consumers Energy Value Function**

Jackson generating Station has a circulating water system that has a single eight-cell induced draft, counterflow cooling tower and an auxiliary cooling water system that has a two-cell induced draft, counterflow cooling tower. Each tower consists of a pressure treated Douglas fir structure with PVC fill and drift eliminators, a fan deck made of pressure treated tongue and groove plywood, cell partitions and windwalls made of pressure treated, Douglas fir plywood, fiberglass reinforced plastic (FRP) pipe headers with PVC lateral distribution systems. The current cooling towers have been in service for 22 years with no planned or major maintenance performed on them in that time. The Douglas fir components are delaminating and deteriorating from the wear and tear of the water and the chemical used in the water.

A complete cooling tower health assessment was performed in Fall 2024. That assessments and their findings were categorized as danger (immediate attention required), warning (short-term repair needed in the next 12-18 months), caution (mid-term repairs needed in the next 2-2½ years or future monitoring), and good (long-term repairs needed > 2½ years or no recommendations). Inspection reports are attached.

Investment Type	Generation	Planning Portfolio	Jackson
Facility	Jackson / Jackson		
Executive Summary	The JGS - Main and Aux Cooling Tower Rebuilds project at the Jackson Generating Station involves significant upgrades to the cooling tower systems, which have been in service for 22 years without major maintenance. The cooling towers, made of pressure-treated Douglas fir, are deteriorating due to water and chemical exposure. Scope of Work The project aims to replace various structural components of the cooling towers, including: 4x4 columns, 2x4 longitudinal and transverse girts, 4x4 diagonal braces, splice blocks, brace straps, and hardware Fill media and supports, drift eliminators, wind and partition firewalls, distribution systems, fan decks, and exterior casings Mechanical equipment like fan cylinders will be reused Objectives Mitigate forced outage risk: Prevent unplanned outages due to structural failures Circulating water pump issues due to delamination of partition walls and structural supports would be a 3-day delay. 560 MW derate each time. These are the most common outages with the highest risk. 10% probability of realizing this risk. Deterioration of structural supports causing a cell to collapse would require a 2-4 month forced outage to recover from due to material lead times and scope of work. This carries a probability of 1.5% and escalates by 25% year over year until 2040. Annualized probability of 10% for modeling. Energy inefficiency: Reduce energy loads caused by longer run cycles Environmental: Prevent the release of untreated water Health: Avoid bacteria like Legionella that can cause Legionnaires' disease Structural damage: Address the deterioration identified in the Fall 2024 inspection Alternatives Considered Recommended: Rebuild using fire retardant polyester resin (FRP) with a draft forecast of $14,649,496 between Jan 2027 and Dec 2030. This material is more resistant to chemicals, moisture, and has a longer lifecycle. Candidate: Rebuild using pressure-treated Douglas Fir #2 (PTF) with a draft forecast of $15,821,001 between Jan 2027 and Dec 2030. This traditional material is initially more cost-effective but requires more maintenance. Risks and Consequences Delamination and deterioration: Can lead to blockages in circulating water pump intakes, causing unplanned outages Structural failure: Could result in a collapse, making the cooling tower unusable and shutting down the plant Environmental compliance: Degradation can lead to violations of the plant's permit with Michigan's Department of Environment, Great Lakes, and Energy (EGLE) Potential capacity losses: Estimated at $21,954,189 in the event of a forced shutdown

Investment Overview

Project Details	Environmental Justice Area	No
	Estimate Class	Class 4
	Rate Case Mapping	Gas Generation
	EPM Managed	Yes
	Outage Type	Site
	Scope	Scope of work is to replace the ten cooling tower structures' 4x4 columns, 2x4 longitudinal and transverse girts, 4x4 diagonal braces, splice blocks, brace straps, and hardware. Fill media and fill supports will be replaced. Drift eliminators, drift eliminator supports, and drift eliminator penetration & perimeter seals. Existing wind and partition firewalls will be removed and replaced with single sided ½" plywood wind wall, double sided ½" plywood fire wall, and 2x4 wind & firewall mid-bay supports. Distribution system will be removed and replaced with new headers, laterals, vent pipes, pipe saddles and supports, gaskets and grommets, and distribution nozzles. Fan decks will be removed and replaced. Exterior casings will be removed and replaced. Mechanical Equipment including fan cylinders will be reused.
	Objectives	mitigate forced outage risk Energy inefficiency – Increase energy loads due to longer run cycles to transfer heat from the water cycles. Environmental – Deteriorated cooling tower structures can lead to the release of untreated water onto the grounds surrounding the towers which is reportable to EGLE. Health – Poorly maintained cooling towers can harbor bacteria like Legionella which can cause Legionnaires' disease when airborne droplets are inhaled. Structural damage – The Fall 2024 overall structural health inspection of the main and aux cooling towers identified that the cells need rebuilds to prevent component failures or a collapse of cell(s). Immediate repairs are being performed in 2025 but rebuilds due to age and water related deterioration is needed in the near term to prevent issues that would affect the operation of cells or towers which would impact the plant's dispatchable load capability until corrected.
	Planner Recommended Alternative	Rebuild main and auxiliary cooling towers using fire retardant polyester resin (FRP); $9.551M (unloaded) Initial cost of this option is approximately 7.5% higher the cost of traditional materials like pre-treated Douglas fir which was used in the original construction of JGS cooling towers. The cost has come down considerably over the last 25 years. The material is more resistant to chemicals like those used to treat the plant's water and is unaffected moisture or water. The material has a higher strength than timber and 1¼ times more rigid than timber. The material required less maintenance and has longer product life which contributes to a lower lifecycle cost. The material has high dielectric capability compared to timber which can be conductive when wet. The product's durability, corrosion resistance, and longevity were factors make it more cost effective in the long run than option 2 (pre-treated Douglas Fir). Delamination of partition boards and the deterioration of structural supports leads to them separating from the structure. Partition boards and structural supports then find their way into the circulating water pump suction pits where they can and have blocked circulating water pump intakes/suctions. Such blockages can and have impacted operations to the point of unplanned outages that take the facility offline for 3 days, so the impacted tower is drained, cleaned and refilled. The missing partition boards affect the water flow distribution and leads to cell thermal inefficiency. The higher cooling water temperatures increase the plant's heat rate, meaning more fuel is needed to generate the same amount of power. Missing partition boards from cells provide a path for water to escape the system which is a reportable notice of violation from EGLE. Mitigating measures would need to be put place until an outage as issues arise. In addition to blocking circulating water pump intakes/suctions, the deterioration of the structural supports causes the cooling tower structure to shift, or not properly handling/transferring of loads. The collapse of the structure would be inevitable. This type of failure would make the cooling tower unusable when will shut the plant down until the issue is resolved. Other alternative considered: Rebuild main and auxiliary cooling towers using pressure-treated Douglas Fir #2 (PTF); $8.9M (unloaded) Original construction material for the plant's cooling towers. Traditional material for cooling tower construction. More cost effective initially than rebuilding with fire retardant polyester resin (FRP) but usually requires more O&M maintenance and replacement over the course of the product's life. The material can warp, rot and decay when exposed to moisture, water and chemicals. Cooling towers built from this material have a 25-year service life.

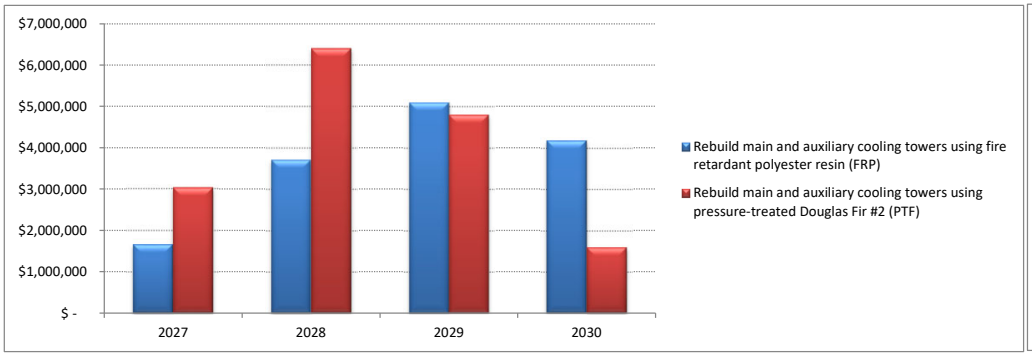
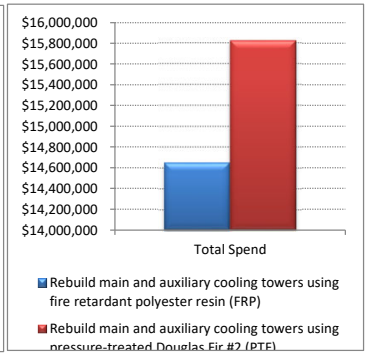
Investment Name: **JGS - Main and Aux Cooling Tower Rebuilds**

Scenario: **Draft**



Value Function: **Consumers Energy Value Function**



Alternative Details	Assumptions	These rebuilds will be equipment outages. One cell at a time during the shoulder months and plantwide outages. Risk: Delamination of partition walls and deterioration of structural supports will continue. failure history: There have at least two occurrences in the last 5 years associated with cooling tower debris and other debris causing a unit derate to the point where forced outages were taken to clean the circulating water pump intake sump pits. Circulating water pump issues due to delamination of partition walls and structural supports would be a 3-day delay. 560 MW derate each time. These are the most common outages with the highest risk. 10% probability of realizing this risk. Deterioration of structural supports causing a cell to collapse would take two to four months to recover from due to material lead times and scope of work. This carries a probability of 1.5%. Due to the age of the cooling towers and failure history, the probability of failure from the status quo/"do nothing" option will increase 25% on a year-to-year basis because the stage of deterioration of the structural components from water wear and age. Given these factors, the annualized assumed probability of failure will be 10% (assuming end year as 2040). Degradation of the cooling towers can lead to water from the cooling towers to the waterways of the state via the storm drain system which is a violation of the plant's permit with Michigan's Department of Environment, Great Lakes, and Energy (EGLE) which is tied to a National Pollutant Discharge Elimination System (NPDES) wastewater discharge general permit. This permit keeps the plant in compliance with the provisions of the Federal Clean Water Act, 33 U.S.C., Section 1251 et seq., as amended (CWA); Part 31, Water Resources Protection, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended (NREPA); Part 41, Sewerage Systems, of the NREPA; and Michigan Executive Order 2019-06. Site has had 2 or 3 events in the last five years, but no notices of violation were issued by the regulatory parties. The basis for notices of violation not being issued was because the plant notified the regulatory parties immediately, the plant's testing after events showed that the tested parameters were not above the stated limits, and the plant instituted corrective measures to prevent reoccurrence. The Environmental Protection Agency (EPA) can impose fines of at least $5,000 and up to $50,000 per day of violation for unauthorized discharges in violation of the plant's NPDES permit. 1% chance of realizing a compliance risk. Potential Capacity losses in the event of force shutdown have been calculated at $21,954,189. The calculations were made using a conservative calculator provided by the capacity forecast team. The CONE value used for this model is $130,930. 75% of CONE was
	Rebuild main and auxiliary cooling towers using fire retardant polyester resin (FRP)	Initial cost of this option is approximately 7.5% higher the cost of traditional materials like pre-treated Douglas fir which was used in the original construction of JGS cooling towers. PROJECT INITIATION & CONCEPT APPROVAL
Generation Planning
Capital

Generation Type: Hydro
Site: Ludington
Unit: 1-6
Date Created: 2/23/2022
Proposed Start Implementation Year: 2024
Project Span Whole Years: 6
Project Title: Ludington 1-6 DCS Control Relay Replacement CA

Problem Description (Section 1-Initial Information):

Ludington Pumped Storage (LPS) units are currently controlled and protected by the original (1970's technology) hardwired electromechanical relay control system, going forward referred to as "the system". The system is comprised of relays mainly in the auxiliary relay room and operator control handles located on the Main Control Board (MCB). The system has outlived its useful life and is failing. The system is not fail-safe in design; does not provide fault tolerance; and the redundancy is inadequate. There are gaps in the system protection scheme. The system is presenting plant operations and maintenance with problems. The Uninterruptable Power Supply (UPS) system is not currently segregated by unit pairs and presents a common point of failure for the plant.

The system is based on electromechanical devices (relays and operator control handles) that wear and have become less reliable over time. The relay contacts wear, and increased resistance has caused intermittent failures. The operator control handles are in a similar state of wear and age and have also experienced intermittent failures. The system will not last until End of Life (EOL) of the units.

The plant was designed using the control and protection methodologies available in the 1970's. Many of the relays in the system fail to a non-protective state. A small subset of examples is as follow:

Emergency Stop Relays (5E) – Each unit has an emergency stop relay. The relay is configured to energize to trip. A failure of this relay results in the unit not being shut down by the relay. There are fourteen legs in the design which energize this relay to trip the unit. A few of them are as follow:

- Turbine Overspeed (125%)
- 345 KV Bus Fault while pumping
- Upper reservoir water level high (Overtopping protection)
- Intake gate closed

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

Many portions of the protective scheme are not fault tolerant. Fault tolerance refers to the ability of a system to continue operating without interruption when one or more of its components fail. As an example, master shutdown relays (5) do not provide fault tolerance. While there are five master shutdown relays for each unit they are not implemented in a redundant fashion. There are five of these relays because when the emergency shutdown function is asked for by the protection scheme there are so many different actions taken that one relay cannot implement them all. Thus, each of the five relays shut down different portions of the process. A failure of any one of the relays will directly affect only the portions of the process tied to that relay. This means that a portion of the equipment (a subset) can inadvertently be tripped while the balance remains in service.

Many critical trip inputs from the relays are not redundant. Redundancy is a system design principle that introduces duplicate components to provide fault tolerance. When a component fails, a backup takes over to ensure the system still performs as designed. A small subset of examples where we rely on one device to provide unit protections is as follow:

- Overspeed switch and aux relay (12X) – One relay contact energizes the emergency stop relay. If the relay fails, we will not shut the unit down as prescribed.
- High draft tube water level (71DWHX) – One relay contact energizes the emergency stop relay. If the relay fails, we will not shut the unit down as prescribed.
- Governor oil tank level low (71GTL) – One relay contact energizes the emergency stop relay. If the relay fails, we will not shut the unit down as prescribed.

Challenges for plant Operations and Maintenance

- The main control board switches are wearing. Even with lubrication and maintenance a number of these switches have the interface with their key or handle worn excessively. Many of our larger main control board switches are no longer in production. There are minimal spares available. Replacement for the more complex switches that have many contacts are no longer readily available and obsolete. We are reliant on custom assemblies for replacements and must commission custom builds. These custom builds also present a problem in long lead times. If failure is observed unit(s) and portions of the plant may remain out of service for extended durations

- The Relay Room is so densely populated with relays that just walking around has caused issues when relays get bumped. As part of the process of routine relays checks the covers are removed and replaced which has caused inadvertent circuit changes.

- Changing a relay(s) can affect multiple circuits and even other units (starting bus, Main Transformer Banks (MTB)) due to their common neutrals. Direct Current (DC) bus grounds can be difficult to find when there is no indication on cause (i.e., alarming).

- Intermittent issues can take months to find and correct. This is due to the lack of active monitoring/measurement that allows for troubleshooting to be performed timely. For each occurrence custom recordings must be setup with ad-hoc hardware to assess what the controls are executing and experiencing.

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

- The system does not provide the proper diagnostic and troubleshooting capabilities.

- During the startup and shutdown process plant operations cannot see the operational state of the unit. Functionality and troubleshooting during start/stop sequences cannot be observed other than by individually observing and testing scenarios with personnel and recording devices (multimeters or digital recorders for electrical signals).

- Start permissives have limited visibility. Critical valve positions are not individually observable as they come to single relay collectively to provide the start permissive. Troubleshooting requires additional effort and resources.

- Several current manual processes cannot be automated preventing the removal of human error potential during startup, shutdown, and other equipment configurations.

- Any updates of equipment and systems that need to be integrated with the unit operation are difficult and expensive to integrate into the hardwired relay logic.

- Automation efforts prove to be difficult if at all even possible with the hardwired relay logic. Changes to operating criteria are difficult to implement, test and verify and costly and time-consuming.

- Training for Operations is limited to studying procedures as the system does not provide a testing and simulation environment.

- The unit overtopping protection needs improvements that can't easily, and cost efficiently be implemented into the current legacy relay-based control system (pump start lockout above 932’ reservoir elevation, overtopping protection and system control of how many units are allowed to pump above 940’ and 941’ respectively).

As a result of the system failing the unit can come off-line, become unavailable, or experience derates. In addition, as these devices also serve to provide equipment protection their failure can result in significant equipment damage up to and including destroying significant parts of the unit and/or plant potentially rendering the unit(s) and/or the entire plant unavailable for years. The potential costs of such repairs could easily rise to hundreds of millions of dollars. In addition, there are significant gaps in the original protection design. Consumers Energy is exposed to substantial risk due to the state of the system.

LPS will become more important to the stability of the grid as renewable generation (solar and wind) sources increase and as fossil generation (gas and coal) is decommissioned. LPS provides the Midcontinent Independent System Operator (MISO) grid support by delivering frequency and voltage support (reactive load generation) that replaces the support that will be lost when our gas and coal units are decommissioned. Providing grid stability in conjunction to our generation realignment is an important aspect to our corporate strategy.

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

Alternative Solutions/Alternatives Considered

Alternative Solutions (Section 2):

Alternative #1 - Do nothing (20-Year Payback)

Total Cost of doing nothing: $29.6M (51% dollars)

The costs associated with doing nothing include costs associated with the damage occurring as a result of system failure(s) and the units not being available to run and support our renewable strategy. There are other costs related to doing nothing such as maintaining the plant and operational issues that can make the units unavailable for relatively short periods of time, however the major impacts are derived from system vulnerabilities with respect to their protection functions.

DAMAGE
The system provides the basis for personal and equipment protection. If we do nothing, we will continue to experience failures of the system. The frequency of errors is progressively getting worse as system components continue to age. Eventually a failure or combination of failures could result in catastrophic damage to a unit or the entire plant rending it unavailable for up to a year or more. This would cause significant impacts to our ability to serve our customers.

Relay fault probability used is based on data from the Overtopping Fault Tree analysis report. In the report the Savanna component fault probability database was consulted, and the component fault relay probability used as part of the overtopping fault tree analysis was 0.001 failures per day.

ALREADY OCCURED
Recently the plant experienced an incident where unit 4 entered shutdown as it went into pumping mode before the generator breaker was closed and the unit synchronized. As mentioned in the problem statement there are gaps in the logic, a pumping mode should not be permitted until unit 4 had been synchronized. In addition, as part of the event the cross trip to unit 1 did not take place and the unit 4 motor was operated synchronously (as its exciter had been taken offline when unit 4 went into shutdown). Damage to the unit 4 generator field along with other equipment may/could have occurred. The plant is still looking into the incident; however, it is difficult to ascertain what truly happened with the current system in that the protections are not all contained in one system. Portions of the protection are in the system relays and portions are in the protection relays. This event is indicative of the system risks. Damages for this event can easily reach $60M and make a unit unavailable for months which would cost another $15M depending on Local Marginal Price (LMP) and market demands. The total cost for an event of this nature could reach $75M (100% dollars).

POTENTIAL EVENTS
The following provides a description of three other scenarios that provide significant system failure(s) risk to the operation using the old technology. The three scenarios below are a small subset of the control system vulnerabilities. It should be noted that these are all low probability

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

and high cost/consequence events. Based on data from the Overtopping Fault Tree analysis report the fault probability database was consulted and the relay fault probability of 0.001 failures per day was used.

Scenario 1: Turbine Overspeed Switch and Aux Relay (12X)
The system provides unit overspeed protection through a relay which is energized to trip. If the relay fails when needed during an overspeed event the damage associated with an overspeed event could be to damage the rotor bearings and the rotor itself. This would make the unit unavailable for years of time and costly repairs. It is estimated the repair cost could reach up to $160M and the loss of the unit for years another $70M for a total of $230M. Based on data from the Overtopping Fault Tree analysis report the fault probability database was consulted and the fault probability of a relay is 0.001 failures per day; the fault probability of the wicket gates failing to close is 0.0002 per day. This results in a total probability of failure of 2E-7 per day, which is 7.3E-5 per year.

7.3 E-5 x $230M = $16,790/year x 20 years = $336K x 6 units = $2M (100% dollars)

Scenario 2: Upper Reservoir Water Level High (Overtopping Protection)
As a FERC regulated facility, dam safety is of the utmost importance. Consumers Energy is under constant scrutiny by regulators to provide safe reliable operations. Overtopping protection is very high on the priority list. Proving the effectiveness and reliability of dam safety protection schemes for overtopping protection is a must do. The overtopping protection protects corporate and public, life and property. The current plant overtopping protection scheme has 4 levels of protection. A breach of the overtopping protection schemes would require disclosure to our regulators which could trigger a requirement to install an emergency spillway, which may cost in excess of $150M (100% dollars).

No cost with regard to this scenario has been placed into the cost of this solution as the probability is negligible, however this scenario demonstrates the magnitude of cost were the event to occur.

Scenario 3: Loss of the starting bus
As the system provides protection for the plant starting bus, a failure in its protection would leave the plant without many if not all of its units for years depending on the severity of the event. This estimate uses a loss of three units for 1 year It is estimated that the replacement of the starting bus would cost around $100M and losses in revenue of $25M (100% dollars).

No cost with regard to this scenario has been placed into the cost of this solution as the probability is negligible, however this scenario demonstrates the magnitude of cost were the event to occur.

HIGHER FUTURE PROJECT INTEGRATION COSTS
There are many projects being executed at the plant. The costs for these projects to integrate with the system is higher and costs projects an additional $70,000 per year. In total that amounts to $1.4M over the 20-year payback period.

The cost for the 20-year payback period is $1.4M (100% dollars) or $.7M (51% dollars).

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

PLANT OPERATION AND MAINTENENCE COSTS

The operation and maintenance costs of maintaining and working with the system are estimated to be $100,000 per year per unit. This includes but is not limited to the extra time it takes to troubleshoot issues; the cost to maintain the system as best as possible; and the extra overhead related to operations. Over the period of 20 years the total is $12M (100% dollars).

The cost for the 20-year payback period is $12M (100% dollars) or $6.1M (51% dollars).

FORCED OUTAGES

Increased Random Outage Rates (ROR) due to continued failures of the system may cause unit outages and/or derates.

Using NERC Generating Availability Data System (GADS) data and supplemental knowledge of plant management that the units are worth $5M – $6M in the high season (July – September) and the expected forced outages based on past events it is estimated that there will be revenue loss of $1.75M (100% dollars) in the future year. It was then assumed that there will be a rise in forced outages due to the relays at the rate of approximately 3% per year. Projecting this out over a 20-year timeframe (the period that choice 2 & 3 would be expected to be in service before further action) would result in a cost of $42.9M in lost revenue.

Total cost breaks down for the 20-year payback period to:

Damage:	$2M (100% dollars) or $1M (51% dollars)
Project Integration:	$1.4M (100% dollars) or $.7M (51% dollars)
Operation & Maintenance:	$12M (100% dollars) or $6.1M (51% dollars)
Forced Outages:	$42.9M (100% dollars) or $21.8M (51% dollars)

The cost for the 20-year payback period is $29.6M (51% dollars).

Alternative #2 - Replace hardwire relay control system with Distributed Control System (DCS) and segregate the UPS (20-year payback)

Total cost of putting in a DCS: $13.4M (51%dollars)

Installing a modern Distributed Control System (DCS) will allow a system that will be able to be used and maintained for the life of the unit. It will increase site availability by reducing failures caused by aging relays and allowing better diagnostic tools such as historian trends, live logic viewing, alarm messages and related operator responses, and common Human-Machine Interface (HMI) control for all the plant equipment in a central system. A modern control system also allows for additional process automation further reducing error potential during operations and associated impacts.

The DCS Control Relay Replacement Study project (PH-20106) evaluated the detailed scope, budget, and schedule to replace the existing hardwired controls at the Ludington Pumped Storage (LPS) facility with full Emerson Ovation Distributed Control System (DCS) control. The study included the following scope:

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

Modernization of the control room including removal of many of the operator control handles on the Main Control Board (MCB) to be implemented in the DCS as well as optimization of the layout of the control board for operational efficiency. In addition, the operator control console would be replaced with a modernized console with dedicated alarm displays and alarm response aids. The central alarming function the DCS provides enhances reliability of the units. As an example, DC bus grounds will be brought into the DCS for diagnostic and troubleshooting purposes.

A high fidelity DCS simulator will be provided for the project. The simulator will provide operator training capabilities prior to implementation of DCS control and monitoring at the plant. The simulator will be capable of replicating all logic and control schemes for all six (6) units. The simulator will allow testing of logic changes before they are implemented on the "actual" units which will enhance reliability. Simulation will be a primary means to test and verify logic operation before the implementation outages for each unit. This will help reduce risks during this project.

Turbine Supervisory Panels - Remote control functions associated with the turbine datalink will be migrated to hardwired DCS control as part of this project to replicate the existing plant hardwired controls from the MCB panels.

Pony motor control and monitoring will be migrated to the DCS.

The existing UPS system at the plant has a rating of 20KVA and provides 120VAC power to equipment for all six (6) units. This UPS system has reached its maximum capacity and requires an upgrade to support future loading requirements. The new DCS hardware installed as part of this project requires reliable and redundant power distribution for plant operations. An evaluation of the UPS system was performed. The results determined that a full upgrade of the UPS system is required to support the project and maintain sufficient spare capacity for future projects. Three (3) separate 20KVA UPS systems will be installed to allow unit pair separation (Unit 1 & 2, Unit 3 & 4, and Unit 5 & 6) to provide reliable and redundant power distribution throughout the plant.

The cost for the 20-year payback period is $13.4M (51% dollars)

Alternative #3 - Replace all Control Relays and a portion of the operator control handles with new ones and replace and segregate UPS (20-year payback)

Total cost of replacing the relays: $22.7M (51% dollars)

A complete replacement of all control relays to reach end-of-life (EOL) of the plant would require an immense undertaking to de-terminate the wiring on close to a thousand relays, replace the relay and rewire to the previous state. The system would require a complete recommissioning of the control system and post maintenance testing. Validity of the testing would be difficult. The amount of time required to do this work would require the work to be performed over multiple outages and would be difficult to perform without complete site outages. There would be increased risk of possible unit trips if attempted to perform under individual unit outages due to common systems and interrelated control signals.

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

This option does not provide benefits to resolve all the issues mentioned in the problem definition. Trouble shooting issues are still limited by the lack of tools available as compared to a modern control system. Many of the problems that occur over time are the result of the system itself being comprised of hundreds of electro-mechanical relays that eventually wear out and fail. Common operator interface of a DCS, along with operating events and alarms brought into a system-wide historian and allowing full historic trending of the process leading up to the issue, is not available with the relay-based control system.

The cost of replacing the relays will also include the following costs as they are not mitigated by the solution as in reality there is no alternative that will do what a DCS does. The following items are detailed in the cost of doing nothing choice and have been scaled as to their associated costs with this choice.

Damage:	$2M (100% dollars) or $1M (51% dollars)	(Scale Factor 1)
Project Integration:	$1.4M (100% dollars) or $.7M (51% dollars)	(Scale Factor 1)
Operation & Maintenance:	$10.8M (100% dollars) or $5.5M (51% dollars)	(Scale Factor .9)
Forced Outages:	$21.5M (100% dollars) or $10.9M (51% dollars)	(Scale Factor .5)
Cost to replace relays:	$9.0M (100% dollars) or $4.6M (51% dollars)	(Scale Factor 1)

The cost for the 20-year payback period is $22.7M (51% dollars).

Recommended Alternative Benefits/Objectives (Section 3):

Recommended Alternative #: 2
Recommended Alternative: Replace hardwire relay control system with Distributed Control System (DCS)

Why was this Alternative chosen?

A DCS is recommended for full control of the units at Ludington Pumped Storage. This solution provides a reliable and sustainable method to control and operate the six units at LPS for the remainder of the life of the plant. The DCS solution mitigates gaps in the plant protection scheme. The DCS solution will therefore mitigate the potential of damage at the plant. The DCS will make integration with future projects less expensive. The DCS will reduce the plant operation and maintenance costs.

The architecture of a DCS allows the reduction of electromechanical relays and timers and replacement with electronic input/output (I/O) modules that do not rely on mechanical movements and physical contacts to control the equipment. The DCS can program the sequencing of the equipment using control logic sheets (SAMA - (Scientific Apparatus Makers Association) control functional diagrams) that represents the functionality of hardwired series and parallel relay circuits. The number of physical components that can fail is significantly reduced. Operation sequences can be changed and updated with greater ease and new equipment can be added to the DCS control with less effort and full integration into the system. A DCS also provides appropriate control and trip redundancy that currently does not exist.

The modern DCS provides a complete control solution. HMI graphics provide the operator with easy to use "mouse-click" control of the plant equipment. Process sequences can be automatically

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

controlled to reduce and eliminate operator intervention. Troubleshooting tools such as live logic display, trending and historical review, and alarm with alarm responses improve the diagnostic capabilities and reduces the time required to resolve problems. The DCS can also improve efficiencies and performance by providing more accurate control and monitoring of equipment and processes. Integration of other equipment control systems can be brought into the DCS to provide a single user interface for the operators to monitor and control all equipment with a common alarm system.

There have been several engineering studies performed in the last 15 years to determine the best options for the extended operating life of Ludington Pumped Storage Facility. In 2007 a study was prepared by Devine Tarbell & Associates, Inc. (DTA) (DTA was acquired by HDR in 2009). The study was a condition assessment and life extension study along with a technology upgrade study report.

In 2019-2021 the Data Acquisition System was upgraded to Ovation DCS, also annunciator panels and the sequence of events (SOE) recorder were implemented into the DCS. These upgrades were implemented in three projects which resulted in a fully functional DCS (no equipment control) at the plant.

The recommended project is the natural next step in the migration to full control in the DCS.

Another engineering study was performed in 2021 and established a detailed scope, schedule, and budget to execute a project to expand the DCS to fully control the plant.

Project Benefits/Objectives

- Reduce the risk of potential damage due to the state of the current system.
- Replacement and elimination of worn and less reliable control relays and control board switches with new electronic input/output modules and new relays where needed.
- Future projects that have controls impact at Ludington will cost less
- The number of hardware control relays will be reduced due to the "control" being performed in logic instead of "hardwired" circuits. This will increase reliability and reduce outages and derates.
- Common control and monitoring of system equipment allows operation of the equipment from the HMI graphics and keeps the operator focused on one system instead of monitoring several the systems from several areas of the control room on different devices.
- Alarms are located in one alarm system with alarm management and responses based on International Society of Automation (ISA) 18.2 standards. Integration of external systems will be brought into the DCS for common operator experience.
- Automation of sequences can be programmed to reduce operator interface and improve on efficiency and performance of unit operation.
- Operational efficiencies and performance increases may be achieved by modern process control loops with Proportional Integral Derivative (PID) algorithms.
- Diagnostic and troubleshooting capabilities are greatly enhanced with the use of real-time control logic viewing, historian archive capability of process variables and operating parameters, trending graphs of process variables, start permissives, and logging of system messages.

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

- Additional redundancy for critical trip controls for reservoir overtopping and equipment protections.
- A DCS will provide the long-term path to support the LPS units into the future and through operation towards their End-of-Life (EOL) dates.

Scope of Work

An engineering study was performed in 2021 to provide a detailed scope of work, schedule and budget to complete this project. The document was completed by Worley Energy and lists the scope in detail for the following items: Please refer to the attached engineering study for full details.

- Control Room -Consoles
- Control Room - MCB Panels (move existing Main Control Board devices to DCS graphics control and monitoring)
- Auxiliary Relay Room (relays replaced with DCS controller drops and I/O modules)
- UPS (Uninterruptible Power Supply replacement and reconfiguration for better redundancy and duration and backup of control systems)

Systems included:

- Creep Detector and Brake Control
- Depression Air Compressors 1 and 2 (common to all six (6) units)
- Electrical System (Unit 1 and Unit 2 common electrical equipment listed below, Unit 3 & 4 and Unit 5 & 6 are similar)
    - Station Power Transformer 1 4KV Breaker 1136
    - 4KV Bus No. 1 to Transfer Bus Tie Breaker 1135
    - 4KV Bus No. 1 to Station Power Transformer 11 Breaker 1199
    - 4KV Switchgear 1 Monitoring
    - 4KV Intake Breaker Feeder 1
    - Station Power Transformer 11 to 480V Bus No. 11 Breaker 1166
    - 480V Bus No. 11 Tie Breaker 1165
    - 480V Bus No. 11 Tie Breaker 1160
    - Standby Transformer No. 10 Breaker 1066
    - Generate/Pump Breaker 116
- Exciter
- Generator Motor Heater
- Governor Cabinet Interface
- HP Oil Pumps
- Intake Gate
- Load Break Switches
    - Load Break Switch 115
    - Load Break Switch 116
- Lockout & Protection Relays
- Miscellaneous Solenoid Control
- MT-1 Transformer (common between Unit 1 & 2, Unit 3 & 4 and Unit 5 & 6 are similar)
- Pony Motor (only applicable for Unit 1 and Unit 6)
- Steering Logic
    - All field inputs interfacing with existing control relays in the MCB and Auxiliary Relay Panels
- Water Depression

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

- Engineering and Design and drawings
- DCS hardware, software and logic and engineering and commissioning
- Data links
- Hardwired cable and conduit design, installation, and commissioning
- Integration with current and future projects
- Updating/writing of operation procedures, alarm responses, job aids
- Schedule to be completed over a six-year time period coordinating with unit outages and other project scopes.

Future adaptability and control enhancements or changes are more readily implemented and in shorter time reducing additional future risk. Needs for control enhancements are expected based on lessons learned from events that occur and a needed change to the control logic (= standard work)

Project Justification (Section 4):

Priority Code Title: Critical Projects
Rank: 06
Definition: These projects, if deferred will have a high likelihood of significantly impacting asset reliability in the near term. This category also includes spending to address long-standing safety issues and regulatory commitments that have some flexibility with respect to implementation.

Basis Explanation:

This project removes substantial financial and reputational risks and will save the company money. It addresses the multiple issues presented in the problem description. The presented option provides the highest economical long-term benefit.

Economic Benefit Evaluation (Section 5):

X	**ROR Reduction:**	GADS historic data results can be very subjective on outage and derates with estimates of having a DCS and the amount of time to diagnose and repair the issues (along with the number of units the issue may affect). Estimate 0.3% ROR Reduction.
	O&M and/or PSCR Cost Changes:	
	Changes in Periodic Factor	
	Heat Rate Improvements	

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

	Economics - Parameters for IRR Calculation	
	Other:	Reduction in O&M cost due to troubleshooting issues caused by hardwired relay failures and quicker repair and recover with a DCS will decrease resources and duration cause by the existing system components. This will provide more energy value for our customers in added unit availability and power production from our asset(s). The DCS will reduce risks and provide additional protection for dam safety through improved overtopping protection. This DCS project will provide added equipment protection against severe equipment failures.

Funding and Timing (Section 6):

Identify funding that has already been spent or committed, if any: $82,620.
Timing Impact – Is an outage required? YES
Estimated Outage Duration in Days: 120
Desired implementation year: 2023
Outage Type: Unit

Specify the impact if the recommended implementation year is changed:
Outages would be over a rolling 3-year period during the execution phases with approx. 120-day outage/two units each year and complete site outage of 30 days each year. The project would begin in 2023 and 2024 with engineering and planning. Execution of outages to install equipment would begin in 2025 with units 1&2, 2026 for units 3&4, and 2027 for units 3&4. 2028 would include project closeout.
An engineering study was performed in 2021/2022 to develop a detailed scope, schedule, and budget costing $82,620 (51% dollars).

System Engineer: Kevin A. Ortner

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

Conceptual Estimate (Section 7):

Year	Loaded Cost (51% dollars)	Description	Total Project Cost (CE & DTE)
2023	$1,000,000	Engineering and Design for Units 1 and 2. Total project cost is $1,960,784.00, loaded cost is CE 51% share.	$1,960,784
2024	$2,106,300	Engineering and Design for Units 1 and 2. Total project cost is $4,130,000.00, loaded cost is CE 51% share.	$4,130,000
2025	$3,763,290	Engineering and Design for Units 3 and 4 and execution of project for units 1 and 2. Total project cost is $7,379,000.00, loaded cost is CE 51% share.	$7,379,000
2026	$3,855,090	Engineering and Design for Units 5 and 6 and execution of project for units 3 and 4. Total project cost is $7,559,000.00, loaded cost is CE 51% share.	$7,559,000
2027	$2,351,100	Execution of project for units 5 and 6 and project close out. Total project cost is$4,610,000.00, loaded cost is CE 51% share.	$4,610,000
2028	$250,000	Project closeout. Total project cost is $490,196.00, loaded cost is CE 51% share.	$490,196
	$13,408,400	Total project cost	$26,290,980

Total Cost: $ 13,408,400

Asset Strategy IRR & Justification

IRR:
Justification:
A/S recommends approval of this project based on obsolete equipment and no parts available for old control system. Due to the new license, we need a control system that will last the remainder of the life of the unit and this DCS system will meet those requirements.

DocuSign Envelope ID: 9050B136-95EE-470F-A834-1DE7B63C8BF6

Approvals:

Concept Approval List

Present Need: On approval, this document authorizes the Generation Engineering group to proceed with the work order design and material acquisition pending receipt of appropriate budget authorization. EPM will begin work on this project when a completed and approved charter is in place.

Consumers Energy
Count on Us®

LPS Admin Space Replacement

Problem Description: The temporary administrative trailers have exceeded their service life and are now in poor condition. The current design has inefficiencies and safety impacts that affect daily operations and outage execution.

Key Objective: Create a long-term, cost-efficient replacement for the aging administrative facilities by delivering a safe and consolidated workspace that strengthens operational effectiveness and supports all project and plant personnel for the next 45+ years.

Options considered:

1) Do Nothing
2) Replace trailers with like in kind trailers
3) Replace trailer(s) with a permanent structure

Risks:

- Options 2&3 are not in the 2026 rate case.
  - Option 3 has been in the LTFP for the past 5 years with a 2028 execution date (need to accelerate)
    - Copperleaf value model shows that the permanent building is the best decision
      - (Risk mitigation – A strong business case leads to positive outcome on rates reconciliation)

LPS Admin Key Notes

Factors supporting:

- Favorable litigation outcome ($464M + Fees)
- Aligned with DTE

Funding Needs: ($8.9M in 51% dollars) Reduced original scope by $5M

- 2026 = $4.9M
- 2027 = $4.0M

Funding Strategy:

- 2026 - $4.4M would be funded from the ($10M Elec Supply Checkbook) + Project team would fund $0.5M
- 2027 - $3.0M would be funded in LTFP by Electric Supply + Project team would fund $1M

Note: This strategy will not impact any critical site or EPM project funding

Funding/Schedule Risk

Funding Risks: (at 60% Design)

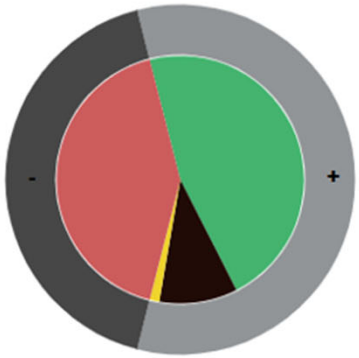
- 2026 = $4.9M
- 2027 = $4.0M

-10% to +25% ($8M-$11.1M)

Value Engineering (VE) to mitigate risks and drive costs down

Schedule Risk/Opportunity

Key Opportunity / Risk	Prob / Impact	Mitigation	Status
Opportunities			
Early Contractor Procurement at 60% Design	High/ Saves 4 to 6 months	Working with Supply Chain to prepare request for proposal for construction manager at risk using major construction contract by February to have contractor on board in March of 2026. Early procurement of contractor assists with value engineering and long lead procurement of materials and building permits.	Discussions initiated with supply chain.
Risks			
Environmental Permitting			
1) Joint Permit Application	Low/ 9 to 12 months	Ensure all work remains above the ordinary high water mark and no permit required.	Reviewed with Environmental
2) National Pollutant Discharge Elimination System (NPDES) permit	High/ 30 to 60 days	Submit renewal application by April 2026 with the revision to relocate one stormwater outfall. No added storm water outfalls. If submitted by April will not affect start of construction in May .	Underway with Environmental
3) Soil Erosion Permit	High/ 30 days	Contractor to submit with final soil erosion design documents. Submit in April 2026 to start work in May.	
FERC Notification	High/60 Days	Site will notify FERC upon Design completion. Submit in March 2026.	
Building Permits	High/30 to 45 days	Contractor to secure with completed designs. To submit by the first of April 2026	
Long Lead Precast Concrete structural components	High/ 20 weeks	As soon as Contractor is under contract the contractor will start procurement with supplier in March 2026	
Delayed occupancy	Low/8 weeks	Site has plan to have personnel grouped into alternate available trailer spaces by area/project of focus to support work and critical communication	



Conclusion

- Now is the optimal time to execute
  - Major work start is anticipated mid 2027
- Cost risks can be managed and maintained within approved rate case targets
- Schedule risks to be managed by EPM Facilities and Operations.
  - Contingency plan ready if the permanent structure is unavailable for occupancy by start of major work
- Solid business case supports the permanent building and positive outcome for rate reconciliation
- We are seeking a move forward recommendation

Copperleaf Value Model – Option 2&3 Comparison

Option 3: New building – Positive NPV of $3,151k

Draft Investment Value
LPS Admin office addition

LPS Admin Summary

Options considered:

1) Do Nothing

2) Replace the temporary trailers with like in kind

Challenges:

- Aging Facilities: The current administration building is at capacity with no additional space available for additional occupancy. The temporary trailers are deteriorating and are reaching the end of useful life and will become uninhabitable. Most trailers are at or beyond their accepted 15 year lifespan.

- Space: The existing facilities cannot accommodate the increased Operations, Engineering, and Project personnel required for outage, project planning and execution with the approaching major outages through 2030 and beyond.

- Operational Inefficiencies: The fragmented office spaces silos, hinders efficient communication and complicates coordination for safety and critical site events.

- Technical support: Additional groups often visit the site for outage support, studies, planning, etc. These individuals also need accommodations the current space is challenged to provide.

- Maintenance Burden: Trailers require constant maintenance—16 HVAC units, plumbing, and electrical systems all designed for temporary systems resulting in high annual repair costs and inefficiencies.

- Gaps to accepted standard(s): The facilities have an insufficient restroom capacity well under acceptable standard. The largest conference room has insufficient size and capacity for site-wide and high-attendance meetings forcing staff into standing-room-only conditions outside of the room creating egress hazards and inefficient communication

LPS Admin Summary

Options considered:

3) Replace trailer(s) with a permanent structure

NOTE: Through value engineering and scope reduction we have reduced the overall costs by $5M

Benefits

- Lifecycle Advantage: Permanent structure avoids repeated trailer replacements, impacts of those replacements over time, impacts to business continuity during those replacement and associated costs
- Consolidated Office Space: Supports all Consumers Energy and DTE staff (Operations, Maintenance, Engineering and Project) with organized work areas under one roof.
- Improved Safety and Collaboration: Eliminates communications silos and enhances safety through significant reduction in foot traffic across areas of the site and adjacent to vehicle traffic areas of the site (high energy) also reducing risk of slippery surface incidents during unfavorable weather.
- Corrected Auditorium (Largest Conference Room) Capacity: Largest room for site-wide meetings and outage planning is designed to accept up to 50 people.
- Reduced Maintenance Costs: Single building built to a higher standard versus maintaining multiple temporary trailers with temporary service equipment (design of HVAC, lighting, restrooms, etc).
- Efficient Infrastructure: Central IT room, compliant restroom facilities, and shared kitchen spaces.

Copperleaf value model assumptions and benefits

Model Assumptions Driving Value

Trailer Replacement Cost: In-kind trailers require a **$4M replacement cycle every ~15 years**, totaling **$16M** through 2069 + decommissioning. (4 replacement cycles)

Recurring O&M Costs: Trailers require **$30k/year** in HVAC/roof/plumbing/electrical repairs and **$5k/year** for portable restrooms.

Displacement-Driven Mileage: Continuing with trailers forces displaced staff to commute from Lakeshore, adding **$100k/year** in mileage costs.

Operational Inefficiencies: Fragmented temporary structures create measurable productivity losses and hinder coordination during critical site activities.

Cost Comparison

In-Kind Trailers: $16.1M lifetime + **$30k/year** repairs + **$100k/year** added O&M

New Building: $8.9M upfront, lowest lifecycle cost and risk

Benefits of New Building

Major Cost Savings: Avoids $16M–$22M in long-term trailer replacement costs and eliminates $135k/year in recurring trailer-related O&M (repairs, restrooms, and displacement mileage).

Lowest Lifecycle Cost: A single $8.9M investment replaces four trailer cycles, reduces maintenance burden, and stabilizes long-term capital planning.

Consolidated Workspace: One secure, modern facility for all site staff, eliminating the inefficiencies of five separate trailers.

Improved Collaboration & Safety: Centralized teams enhance communication, outage coordination, and safety oversight.

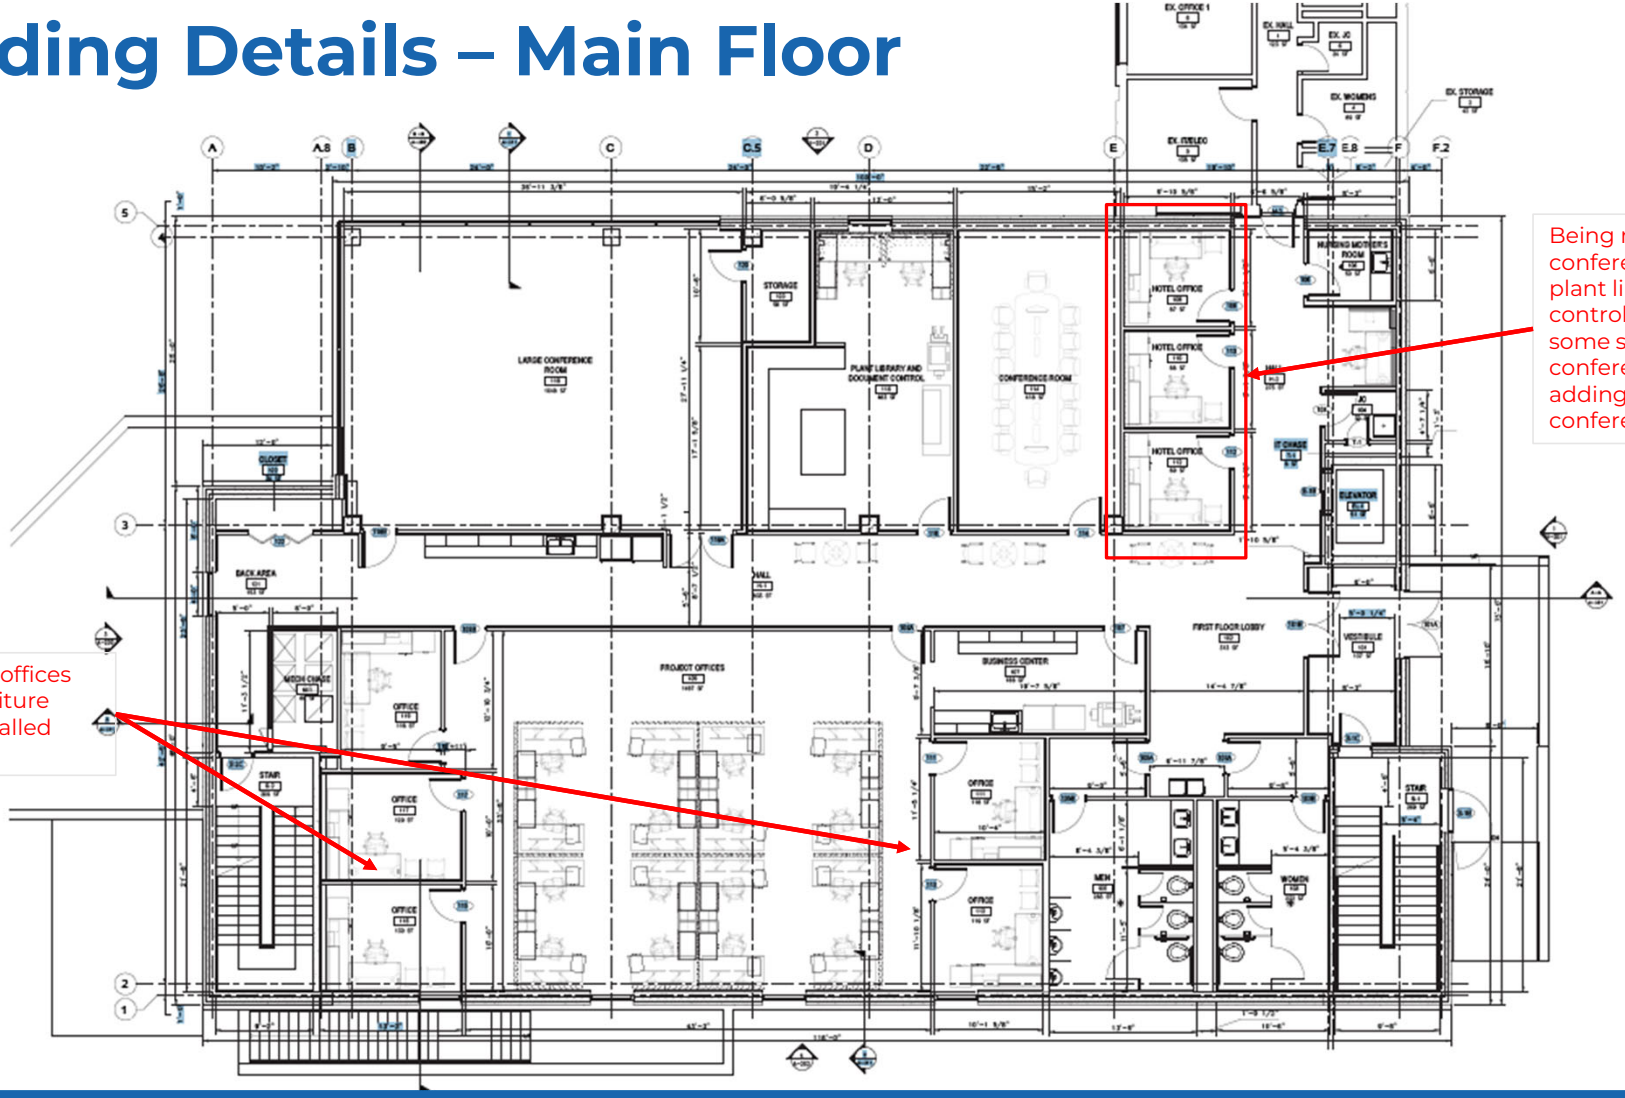
Modern Meeting Capacity: Large conference rooms support site-wide briefings, outage planning, and contractor management.

Efficient Infrastructure: Central IT room, compliant restrooms, shared kitchen, and reliable utilities reduce operational friction.

Visitor-Ready: Adequate space for tours, training, and safety briefings, improving stakeholder engagement.

Replace failing trailers with a permanent facility to eliminate major recurring costs and operational risks, including:

$600k/year in displacement mileage for 20 employees



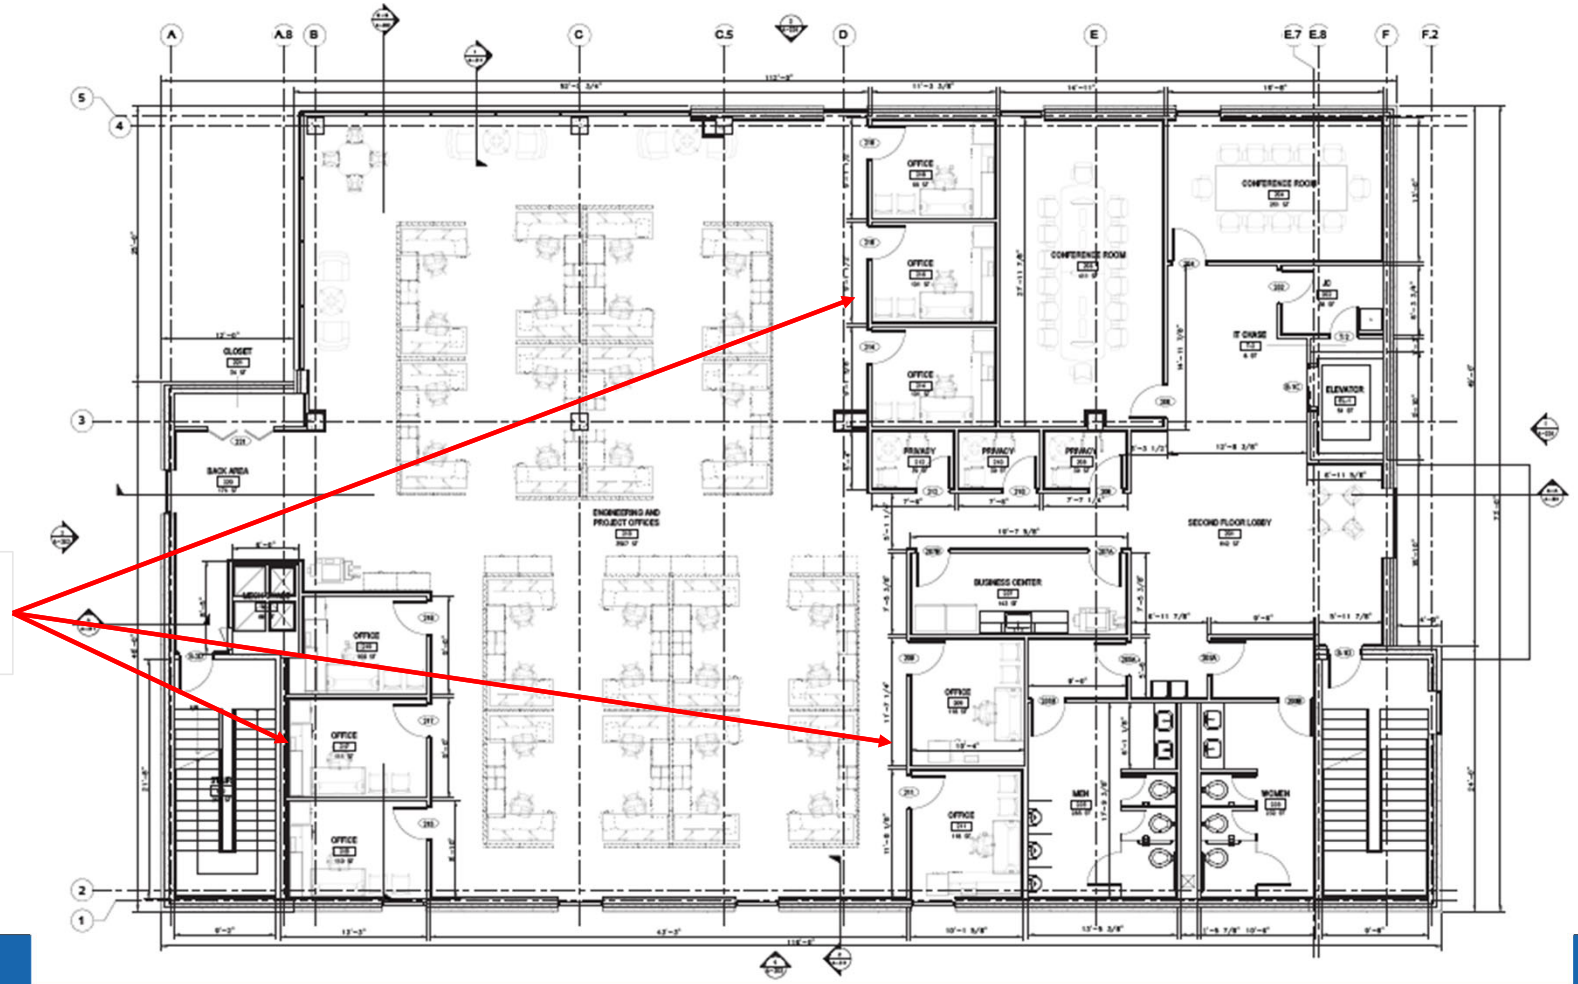
$100k/year in future staffing mileage for 5 employees

$35k/year in trailer O&M and portable restroom rentals

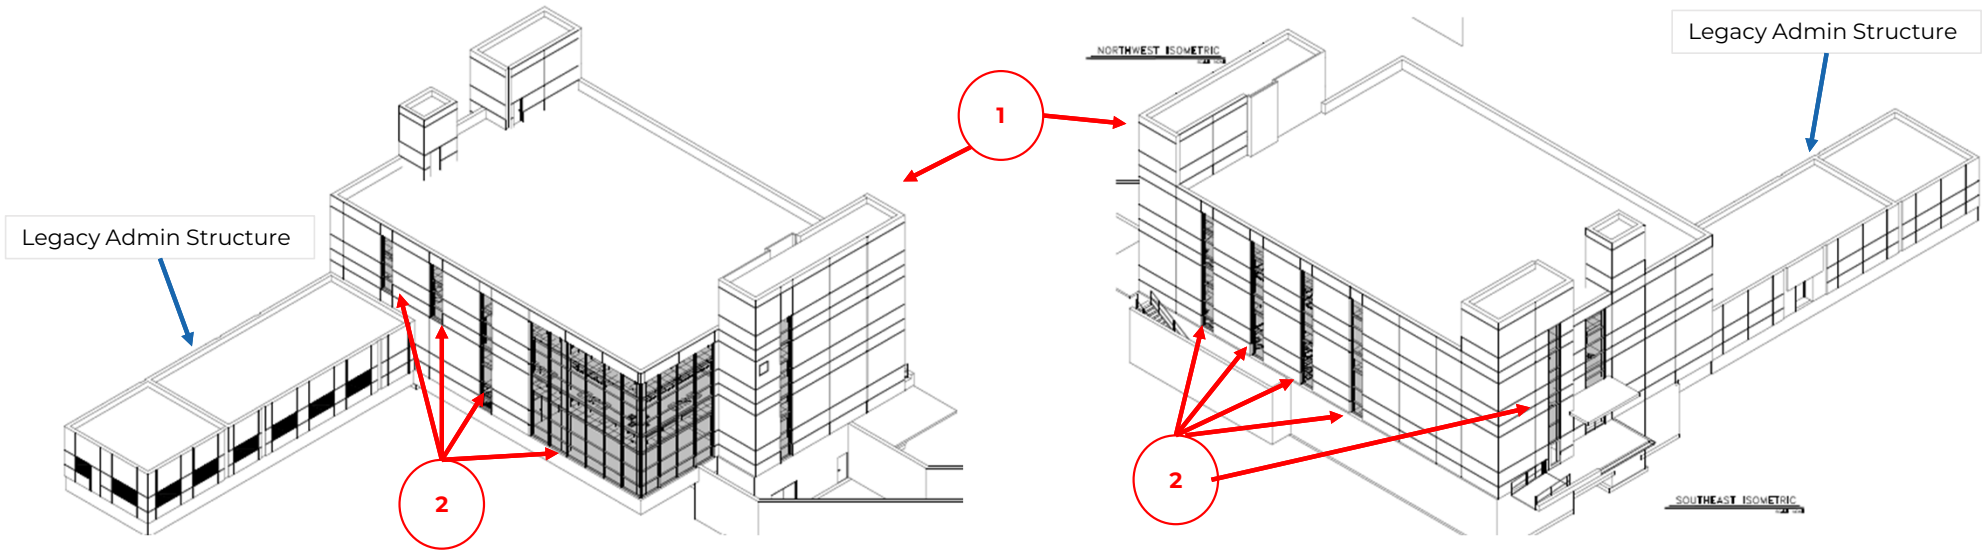
$16.1M–$22M in long-term trailer replacement cycles

Objective: Deliver a permanent building that removes these costs, restores operational efficiency, and supports safe, reliable site operations through 2069 and decommissioning

Building Details – Main Floor



Being removed. Shifting conference room and plant library/document control to the right, adding some space to the conference room and adding space to the large conference room



All cubicles and offices as modular furniture only. No hard walled structure

Building Details – Second Floor

All cubicles and offices as modular furniture only. No hard walled structure

Building Details

In process of value engineering changes:
1. Remove roof floor access on West Stairwell (originally existed when building had concept for 3rd floor)
2. Remove curtain wall windows and go to standard opening (punch openings in the concrete that not floor to ceiling, standard window height only similar to legacy admin structure windows

Concept Approval

Ludington Pumped Storage Dike Load Center replacement.

Date: 6/10/2024

Prepared by: Paul Ohep

Figure 1. Ludington pumped storage station.

Executive Summary

Consumers Energy is undertaking a critical infrastructure upgrade at the Ludington Pumped Storage Station to replace aging and deteriorating Dike Load Centers (DLCs). These upgrades are essential for maintaining the operational efficiency, safety, and reliability of this vital energy facility. The project focuses on replacing the high-priority DLCs that are at significant risk of failure, ensuring continued support for the station's critical functions.

Current Equipment Issues:

The original Dike Load Centers were installed in the early 1970s and have been considered obsolete since the 1990s. Prolonged operational use and environmental exposure have led to significant corrosion and deterioration. Recent failures, including the replacement of DLC14 and DLC16 transformers, highlight the urgent need for this upgrade. Additionally, parts from the replaced DLC1 and DLC2 have been used for repairs, and a new transformer has been ordered to manage future defects.

Priority Assessment and Replacement Strategy:

Plant and dam safety engineers have categorized the DLCs into high, medium, and low priority for replacement. High-priority DLCs are those that are highly likely to become inoperable within five years and provide electricity to pumps that run frequently to maintain adequate drainage of the dike's asphalt liner. This project will replace 10 high-priority DLCs identified as critical for safe and reliable operation.

Financial and Operational Impact:

Failure to replace the high-priority DLCs could result in significant operational disruptions and extended downtimes, with estimated shutdowns potentially lasting up to a year due to obsolescence issues. The estimated financial impact ranges from $24 million up $55 million for Net Energy Value losses and $101.5 Million for potential capacity losses.

Conclusion:

The replacement of the outdated and deteriorating Dike Load Centers is crucial for preventing extensive damages and operational interruptions at the Ludington Pumped Storage Station. This targeted approach ensures that the most critical components are addressed promptly, supporting the facility's long-term operational efficiency and safety. By investing in this strategic upgrade, Consumers Energy is committed to maintaining the reliability of Michigan's energy infrastructure while mitigating potential financial and operational risks.

Financial Summary

Funding Type:	Capital
Initial approved cost:	51% dollars - $4,555,000. 100% dollars – $8,931,372
New revised cost:	51% dollars - $**10,286,051**. 100% dollars - $**20,168,728**

Proposed Start Implementation Year and span

2019, 8-year span.

Problem Description

The Ludington Pumped Storage facility, crucial for Michigan's energy infrastructure, includes twenty 480-volt Dike Load Centers and one 4160-volt Switchgear. These units power one hundred ninety-three dike pumps and additional support equipment critical to the facility's operations. Failure of a Dike Load Center would result in an area of the reservoir where the asphalt liner is inadequately drained, potentially leading to an increase in pore water pressure both on the upstream face and at the downstream toe of the dike.

Issues with Current Equipment:

- **Age and Obsolescence:** The original Dike Load Center equipment was installed in the early 1970s and has been considered obsolete since the 1990s.
- **Corrosion and Deterioration:** Prolonged operational use and environmental exposure have led to significant corrosion and deterioration.

Recent Failures:

- Dike Load Center 14 (DLC14) transformer failed and replaced in 2023.
- Dike Load Center 16 (DLC16) transformer failed and replaced in 2024.
- Other repairs have utilized parts from the old DLC1 and DLC2 load centers, which were replaced last year.
- Due to the lack of spares and long lead times, the current strategy to manage the existing risk involves ordering a new transformer to replace any future defects in the remaining 18 DLCs. This approach will bridge the gap until DLC3 is replaced at the end of next year as part of this project.

Risks Posed by Equipment Failure:

- **Operational Impact:** The Centers are essential for distributing power to the dike drain pumps and pumping relief wells that maintain the structural integrity and safety of the reservoir. For these reasons, Dike pumps are required to be operational.

Critical Functions of the Dike Load Centers:

- **Dike Drain Pumps:** They maintain the drained condition of the dike's upstream face, protecting the asphalt liner from pressure-induced damage.
- **Pumping Relief Wells:** These wells manage groundwater levels, maintaining them at preconstruction levels to prevent dike stability issues.

Consequences of Potential Failure:

- **Study Findings:** An engineering study completed in 2020 indicated that the Dike Load Centers are in poor condition, leading to operational hesitancy in cycling them due to potential recovery failures.

- **Operational Disruption:** Failure would lead to insufficient drainage in parts of the reservoir, increasing the risk of structural failures by elevating pore water pressure upstream and downstream.

Priority Assessment by Plant and Dam Safety Engineers:

- **Priority Categorization:** Plant engineers, along with dam safety engineers, have categorized the Dike Load Centers (DLCs) into high, medium, and low priority for replacement. High priority DLCs provide electricity to pumps that are in service for many hours due to the inherent drainage features of the dike itself. These pumps are critical for providing adequate drainage to the asphalt liner, a vital part of the dike's structural integrity. Therefore, the load centers that supply electricity to these frequently running pumps need to remain operational.
- **High Priority DLCs:** Out of the 20 DLCs, 10 have been identified as high priority based on the aforementioned criteria. This project is focused on replacing these 10 high-priority DLCs to ensure the continued safe and reliable operation of the Ludington Pumped Storage facility.

Conclusion: The necessity to replace the outdated and deteriorating Dike Load Centers is critical, not only for maintenance but also to ensure the facility's operational efficiency and safety. This replacement is needed to prevent possible extensive damages and operational interruptions, with a focused approach on the 10 high-priority DLCs identified by plant and dam safety engineers. The list of high, medium, and low priority DLCs is displayed in Figure 2.

Alternative Solutions/Alternatives Considered

1. Do Nothing - $101.5M in potential capacity losses + minimum $24M in Net Energy Value losses

This option involves not replacing the outdated and deteriorating 480-volt Dike Load Centers and the 4160-volt Switchgear at the Ludington Pumped Storage facility.

Immediate Implications:

- **Continued Deterioration:** The Dike Load Centers and Switchgear, already in a state of significant corrosion and obsolescence, will continue to degrade without any intervention.
- **Operational Reluctance:** As noted, the Operations Department is currently hesitant to cycle the Dike Load Centers due to concerns over their reliability and the potential inability to recover them if they fail.

Long-term Consequences:

- **Increased Risk of Failure:** Ongoing deterioration will likely lead to the eventual failure of the Dike Load Centers, which are critical for the operation of the dike pumps and related infrastructure.
- **Inadequate Reservoir Drainage:** Failure of the Dike Load Centers would result in inadequate drainage of the reservoir's asphalt liner. This can increase pore water pressure both on the upstream face and at the downstream toe of the dike, leading to structural vulnerabilities.

Impact on Facility Operations:

- **Operational Shutdown:** The most severe impact of this option is the potential complete loss of operational capability at the Ludington Pumped Storage Station. Due to obsolescence issues with the high-priority Dike Load Centers, there is no quick way to obtain replacement parts, which are essential for safe operation. Without these crucial components readily available, the pond/reservoir would not be safe for continued operation, resulting in an estimated downtime of a full year.
- **Extended Downtime and potential Capacity Losses**: The unplanned downtime not only involves higher direct repair costs but also results in significant operational and revenue losses due to the plant's inability to generate power during the period of inactivity. Given the obsolescence issues, the assumed shutdown would extend to a full year. From a capacity position, a forced outage would necessitate replacing the lost capacity to avoid future accreditation impacts. The potential capacity loss cost, based on capacity replacement costs valued at 75% of CONE (Cost of New Entry), would be substantial. With CONE set at $127K/MW-year, 75% of CONE equals $95K. Considering the average Zonal Resource Credits (ZRCs) for all Ludington units is 178, if all 6 units were lost for a year, the cost would be:

  178 ZRCs * 6 units * $95K = $101.5 million.

- **Net Energy Value (NEV) and Locational Marginal Prices (LMPs)**: In the event of a forced outage of all six units at the Ludington Pumped Storage Station for a full year, the financial impact can be assessed using Locational Marginal Prices (LMPs). LMP is the cost of supplying the next increment of electricity demand at a specific location in the grid, reflecting supply and demand balance, transmission constraints, and generation availability. The analysis compared similar high and low load days to estimate the impact on LMPs during the outage.
    - Analysis Details:

      During a recent outage period (9/27/23-10/13/23), the average LMP was $33.63/MWh, compared to an annual average of $30.65/MWh.

      Day-Ahead LMP Comparison:
        - Lower Load Days:
            - 29-Sep: $34.96/MWh (Delta: $3.65/MWh)
            - 5-Oct: $32.88/MWh (Delta: $1.57/MWh)
        - Higher Load Days:
            - 3-Oct: $47.02/MWh (Delta: $16.37/MWh)
            - 4-Oct: $39.64/MWh (Delta: $10.11/MWh)
        - The deltas represent the difference between the specific day's LMP and the average LMP for similar days based on load and weather profiles.

    - Financial Impact:

        - It is estimated by our internal economics forecast models that the net energy value (NEV) loss for this scenario would be a minimum of **$24 million** for one year. That estimate is based upon normal conditions. Based on load variability we can expect LMPs to increase by between $3/MWh and $16/MWh which will impact the NEV forecast.

        - At $3/MWh annual average increase in LMPs due to the loss of Ludington, the $24 million net energy loss would increase to **$30 million.**
        - At $16/MWh annual average increase in LMPs due to the loss of Ludington, the $24 million net energy loss would increase to **$55 million.**

Conclusion:

- The 'Do Nothing' option, while avoiding immediate expenditure, poses significant long-term risks including the potential for operational halt as well as significant costs for capacity and energy losses should the site be forced to shut down. The failure to replace the critical Dike Load Centers could lead to irreversible damages and operational challenges, making this approach highly inadvisable.

2. Replace as needed – Internal Estimated Cost of $28,236,219

Description of the Approach:

- **Reactive Replacement:** This alternative involves replacing individual Dike Load Centers at the Ludington Pumped Storage facility only as they fail. While this reactive approach has been previously applied to cabling, where failures were addressed on a case-by-case basis, it's important to note that cabling replacements are significantly simpler. In contrast, replacing Dike Load Centers involves a more complex process. Since the replacements are not like-for-like due to updates in technology and regulation, several additional steps, including system integration and infrastructure modifications, are necessary to facilitate these replacements.

Current State of Equipment:

- **Dike Load Center Maintenance:** Over the years, specific breakers within the Dike Load Centers have been maintained to extend their operational life without replacing entire units. However, this approach is increasingly becoming non-viable due to the growing obsolescence of the parts involved.

Risks and Challenges:

- **Increased Frequency of Failures:** Given the structural deterioration of the Dike Load Centers, failures are expected to become more frequent.
- **Risk of Operational Disruption:** The lengthy lead times required for the design, procurement, and installation of replacement units introduce significant risks. Should multiple Dike Load Centers fail simultaneously, the facility could experience substantial operational disruptions. The complex engineering planning necessary for each unplanned replacement extends these lead times further.
- **Inconsistency in Installations:** Replacing components on a piecemeal basis as they fail leads to non-standard, one-off installations. This inconsistency can complicate maintenance procedures, escalate costs, and diminish overall system efficiency.

Long-term Implications:

- **Continued Reliability Issues:** The approach does not address the underlying issue of aging and obsolescence across all Dike Load Centers but rather postpones comprehensive solutions.
- **Operational Inefficiency:** As more components are replaced on an as-needed basis, the system may become a patchwork of old and new technology, potentially decreasing operational efficiency and increasing maintenance complexity.

Financial Impact:

- **Cost Escalation:** Due to the inefficiencies of this option and the complexities involved in engineering planning and procurement of components, the cost estimates for replacing the high priority DLCs are escalated by an estimated 40%. These increased costs are attributed to the emergency nature of unplanned replacements, which require rapid response and often premium pricing for expedited services.

- **Estimated Project Cost:** Consequently, the total estimated project cost for this approach, factoring in all associated inefficiencies and complexities, is estimated at $28,236,219 in 100% dollars. This figure reflects the significant financial burden imposed by the ad hoc replacement strategy under conditions of urgency and operational necessity.

Conclusion:

- While this option allows for spreading out expenditures over time and addressing issues as they arise, it carries significant risks of unplanned operational halts and safety concerns. The piecemeal approach might also lead to increased costs over time due to emergency replacements and the inefficiencies of managing a non-standardized system. Therefore, this option, though seemingly less capital intensive initially, will lead to higher overall costs and operational challenges.

3. Option 3 - Staged Phased replacement of high priority DLCs only - Initial internal estimate of $8,931,372 (100% dollars), new revised internal estimate $20,168,728 (100% dollars)

This option proposes a structured and phased replacement of the ten most critical Dike Load Centers at the Ludington Pumped Storage facility. This plan is designed to prioritize the replacement of units that are most problematic first, with subsequent phases targeting units that are currently less prone to failure. The other 10 DLCs will be considered under a different project once the data suggests that replacement is warranted.

Planned Phases of Implementation:

- **Priority-Based Replacement:** The initial phase targets the Dike Load Centers that are in the worst condition or that have shown the most frequent issues. This approach mitigates the most immediate risks to facility operations.
- **Subsequent Phases:** Following the initial replacements, the remaining Dike Load Centers would be replaced in a planned sequence over the next six years, based on their assessed condition and risk of failure.

Benefits of the Staged Approach:

- **Risk Management:** By prioritizing the most critical replacements first, this plan not only effectively manages the risk of sudden failures that could disrupt operations but also ensures that the remaining Dike Load Centers continue to operate reliably for several years. The strategy includes utilizing parts from the DLCs that are being decommissioned to stock an inventory of spare and refurbished parts. This approach will provide a robust support system for the Dike Load Centers that are not scheduled for immediate replacement, thereby extending their operational lifespan and enhancing overall plant resilience.

- **Operational Continuity:** A phased approach ensures that replacements are done systematically, minimizing the impact on daily operations and allowing for better planning and resource allocation.
- **Equipment Compatibility:** Implementing a uniform replacement strategy across all units ensures that the new equipment is compatible, avoiding the complications associated with non-standard, one-off installations.

Long-term Strategic Advantages:

- **Enhanced System Reliability:** With new and compatible equipment installed in a phased manner, the overall reliability of the Dike Load Centers is greatly improved, ensuring stable operations for the foreseeable future.
- **Cost Efficiency:** Although this approach requires upfront planning and investment, it is more cost-effective in the long term compared to emergency replacements or piecemeal upgrades. It allows for budget predictability and can leverage bulk procurement discounts.

Option 4 – Full replacement of all 20 DLCs. Internal Estimated Cost - $37,827,823.(100% dollars)

Option 4 proposes a comprehensive replacement strategy for all 20 Dike Load Centers (DLCs) at the Ludington Pumped Storage facility. This option extends beyond the high-priority DLCs addressed in Option 3 to include the remaining 10 DLCs, which have exhibited significantly fewer failures and operational issues over the past five years.

Rationale for Exclusion from High Priority List:

- **Lower Failure Rates:** The 10 DLCs not included in the high-priority list have shown considerably lower failure rates. These units primarily consist of DLCs with dry wells where the pumps have not been operating frequently.
- **Operational Observations:** Due to the minimal operational demand on these DLCs, the wear and stress on components have been substantially less, leading to a decreased likelihood of immediate failures.

Financial Considerations:

- **Cost of Full Replacement:** The total cost for implementing Option 4, which entails replacing all 20 DLCs, is estimated at $37,827,823 (100% dollars). This figure represents a significant increase from the initial estimates made five years ago, which did not account for the escalated costs due to inflation, increased material costs, and more comprehensive engineering requirements now deemed necessary.
- **Comparison to Reduced Scope:** While Option 4 ensures that all components are uniformly modernized and potentially reduces future disparate maintenance schedules, the additional cost compared to Option 3 is considerable. Given the lower risk associated with the 10 non-high-priority DLCs, the additional expenditure does not proportionately increase the value or return on investment when compared to the focused scope of replacing only the high-priority units.

Conclusion: Option 4, while offering a uniform upgrade across all DLCs and potentially simplifying future maintenance, does not present a significantly higher value over Option 3 given the substantial additional costs involved. The decision by subject matter experts in engineering to prioritize Option 3 over Option 4 is based on a strategic assessment of risk, operational need, and financial efficiency. The comprehensive replacement of all 20 DLCs under Option 4 does not align sufficiently with the incremental benefits when weighed against the additional financial investment required.

Recommended Alternative: Option 3 - Staged Phased replacement of high priority DLCs only - Initial internal estimate of $8,931,372 (100% dollars), new revised internal estimate $20,168,728 (100% dollars)

In evaluating the options for addressing the critical condition of the Dike Load Centers at the Ludington Pumped Storage facility, a comprehensive analysis of operational, financial, and technical factors has been conducted. The following section outlines the justification for selecting Option 3, the staged phased replacement plan.

1. **Risk Mitigation:**
    - **Immediate Risk Reduction:** By prioritizing the replacement of the most deteriorated Dike Load Centers, this plan directly addresses the highest risk components within the system. This proactive measure prevents potential failures that could lead to significant operational disruptions or safety concerns.
    - **Controlled Risk Exposure:** The phased approach reduces the likelihood of encountering multiple failures simultaneously, a critical factor considering the long lead times required for designing, procuring, and installing new equipment.
2. **Operational Continuity and Efficiency:**
    - **Minimized Operational Disruption:** Staging the replacements ensures that the facility remains operational without significant downtime. Replacing equipment in a controlled, planned manner prevents the sudden loss of capacity that could result from emergency replacements following unexpected failures.
    - **System Uniformity and Standardization:** As replacements are made systematically, the new installations will be uniform and standardized, which significantly simplifies maintenance and operation. This uniformity ensures all components communicate and function optimally within the system, enhancing overall operational efficiency.
3. **Cost Management and Budget Planning:**
    - **Predictable Expenditure:** A phased plan allows for better financial planning and resource allocation. Budget impacts are spread over several years, which can be

accommodated more easily within annual capital budgets, avoiding the financial strain of unplanned, large-scale expenditures.

- **Economies of Scale in Procurement:** Purchasing equipment in planned stages rather than as one-off replacements can reduce costs through bulk buying and potentially negotiating more favorable terms with suppliers.

4. **Long-term Strategic Benefits:**

- **Enhanced Longevity and Reliability:** Systematically upgrading the Dike Load Centers ensures that all components are modern, robust, and capable of meeting the operational demands of the facility. This not only extends the life of the infrastructure but also boosts its reliability and performance.

Conclusion:

The selection of Option 3, a staged phased replacement plan, is justified based on its comprehensive approach to managing the inherent risks associated with the Ludington Pumped Storage facility's Dike Load Centers. This option balances the need for immediate action on the most critical components with the practicalities of budget, operational continuity, and long-term reliability.

Budget Revision Justification

The initial budget for the replacement of the Dike Load Centers (DLCs) at the Ludington Pumped Storage facility was set over five years ago, based on a 'like-for-like' replacement strategy. Since then, the project estimate has more than doubled, primarily due to significant changes in the technical requirements of the replacement units. The detailed analysis of these changes highlights several key factors contributing to the increased cost:

1. Changes in Size and Design Requirements:

- **Increased Physical Size:** The replacement DLCs are now 2.5 to 3 times larger than the original units. This size increase is mainly due to current industry standards and regulatory requirements not in place or anticipated during the initial budgeting.
- **Foundation Modifications:** The larger size of the new DLCs necessitates the demolition of the existing foundations and the construction of significantly larger ones. This requirement was not included in the original plan, which had assumed the new units would fit the existing foundations.

2. Infrastructure and Installation Adjustments:

- **Conduit and Wiring Changes:** The original project plan assumed that the new DLCs could use the existing pathways for wiring and cabling. However, due to the changed positioning and increased size of the new units, this is no longer feasible. Additional conduit installation is now necessary, along with more extensive wiring than previously planned.

- **Junction Box Installation:** The new layout and increased complexity of the electrical connections require the installation of additional junction boxes. These elements are essential to safely manage and distribute the electrical loads from the larger DLCs, further adding to the project cost.

3. Unforeseen Technical Challenges:

- **Engineering and Design Revisions:** The significant alterations in the project's scope, necessitated by the larger size and different configuration of the replacement DLCs, have required additional engineering and design work. This revision process has introduced delays and increased costs associated with specialized labor and technical expertise.

Conclusion:

The substantial increase in the budget estimate for the Dike Load Center replacement project at the Ludington Pumped Storage facility is a direct result of changes in the physical size of the units, enhanced regulatory requirements, and the complexities involved in retrofitting new technology into an existing infrastructure. These factors were not fully anticipated in the initial budget, resulting in the need for a revised financial plan that reflects the current project realities.

Scope of work

This scope of work details a revised strategy focusing specifically on the replacement of high-priority Dike Load Centers (DLCs) at the Ludington Pumped Storage facility. This initiative spans a four-year timeline and is designed to address the most critical DLCs that have experienced multiple failures over the past five years, ensuring reliable and safe operation of the plant.

Project Details:

High-Priority DLC Replacement:

- **Objective:** Implement a phased replacement of the ten most critical 480 Volt Dike Load Centers based on an assessment by the environmental and dam safety teams.
- **Tasks:**
    - Demolish existing structures and construct new foundations as needed for the modern DLCs.
    - Install new Dike Load Centers that comply with current regulatory standards and operational requirements.

Utilization of Existing Equipment:

- **Objective:** Efficiently utilize existing resources by repurposing used and recently replaced dry transformers and electrical equipment as spares for the remaining lower-priority DLCs.

Phased Implementation Schedule:

- **2023:** Complete the replacement of DLCs 1 & 2 (completed).
- **2025:** Replace DLCs 3 & 4, focusing on critical components and integration with existing plant systems.
- **2026:** Address DLCs 17 & 16, incorporating lessons learned and feedback from previous installations.
- **2027:** Update DLCs 15 & 5, ensuring continuity and system integrity.
- **2028:** Finalize replacements with DLCs 12 & 11, completing the priority updates.

This targeted approach allows for a focused upgrade of the most critical components within the facility, aligning resource allocation with the most immediate needs for reliability and safety. By prioritizing high-risk DLCs and strategically scheduling their replacement, the project ensures ongoing compliance with safety and operational standards while optimizing the use of existing resources. This phased strategy minimizes disruption and maximizes the efficacy of the upgrades, ensuring the long-term sustainability of the Ludington Pumped Storage facility's operations.

Funding and Timing

- Funding that has been previously committed for this project: $4,278,409 (51% dollars)
- A Scheduled outage is required for this project.
- Desired implementation year: first year spend 2019 with installation and closeout finishing 2029.
- System Engineer: Tarik Butrus

Conceptual Estimate

Year	Loaded Cost	Description
2019	**$43,747**	51% dollars. Engineering and planning
2020	**$668,263**	51% dollars. Engineering and planning
2021	**$1,013,244**	51% dollars. Engineering and planning. Procurement and preparation for installation
2022	**$1,665,599**	51% dollars. Engineering and planning. Procurement and preparation for installation
2023	**$887,558**	51% dollars. Engineering and planning. Installation of DLC 1 & 2
2024	**$679,492**	51% dollars. Engineering and planning.
2025	**$1,186,497**	51% dollars. Installation of DLC 3 & 4
2026	**$1,309,572**	51% dollars. Installation of DLC 17 & 16
2027	**$1,308,113**	51% dollars. Installation of DLC 15 & 5
2028	**$1,421,968**	51% dollars. Installation of DLC 12 & 11
2029	**$102,000**	Monitoring, Post Maintenance testing, Documentation and Closeout

Total Cost: 51% dollars - $10,286,052 100% dollars – $20,168,728

Asset Strategy Approval Comments

Asset Strategy endorses the reduced scope approach of Option 3, focusing exclusively on replacing high-priority Dike Load Centers at the Ludington Pumped Storage facility. This decision is based on a detailed risk assessment and cost-benefit analysis performed by our engineering experts, who recommend prioritizing replacements where they are most needed due to repeated failures in the last five years. By concentrating resources on the most critical areas, we ensure a cost-effective allocation of capital while maintaining operational reliability and safety.

This investment **is** included in the current electric rate case.

Amount set for Bridge year: $990,000

Amount set for test period: $852,000

Ludington Pumped Storage Unit Governors

Date: 6/10/2024

Prepared by: Paul Ohep

Figure 1. Ludington pumped storage station.

Executive Summary

The Ludington Pumped Storage Plant Unit Governor systems are essential for hydraulic control and overall plant safety. Currently, the system is obsolete and lacks redundancy, posing significant risks to reliability and safety. A comprehensive upgrade is needed to address these issues.

Problem Description

The governor system controls water flow through wicket gate adjustments, managing various operational modes, including emergencies. It is identified as high-risk due to its lack of redundant controls and mechanical defenses.

Current Challenges

The Atlas electrical controller, installed in the early 2000s, lacks OEM (Original Equipment Manufacturer) support and essential parts. Only one spare controller exists for all six units, and its reliability is uncertain. Additionally, the controller's limited compatibility with the plant's Ovation system complicates troubleshooting. Mechanical failures frequently impact wicket gate operations, and historical oil pump failures risk operational mechanisms.

Alternative Solutions Considered

Do Nothing: Estimated at $19.8M per occurrence, this option poses high failure risks, potential capacity, and NEV losses, and increased dam failure risk.

Controls Replacement Only: Estimated at $4.0M, this option does not address critical mechanical components, leading to incomplete risk mitigation.

Partial Replacement (Selected Option): Estimated at $17,719,930, this approach includes a selective upgrade of control and mechanical systems, integrating with the Ovation system. It enhances reliability, ensures spare part availability, and improves safety.

Conclusion

The partial replacement option is chosen for its balanced approach, addressing critical risks without unnecessary expenditure. It ensures long-term stability and safety by upgrading both control and mechanical components, aligning with industry best practices and leveraging modern technological advancements.

Financial Summary

Funding Type: Capital

Cost: 51% dollars - $**9,037,164**. 100% dollars - $**17,719,930**

Proposed Start Implementation Year and span

2022, 8-year span.

Problem Description

The Ludington Pumped Storage Plant employs a sophisticated governor system responsible for hydraulic control over water flow through the plant's pump/turbine system. This system is critical for managing the unit's operations across various modes, including emergency scenarios, power generation, and mechanical safety.

System Description and Issues

1. **Governor System Functionality:**
    - **Primary Role:** Controls water flow through adjustments in wicket gate positions, influencing power output levels.
    - **System Components:** Utilizes high-pressure oil for operating servo motors linked to wicket gates.
    - **Operational Scope:** Ensures smooth transitions in operational modes such as generation control, pump operations, and emergency dewatering.
2. **Critical Risk Factors:**
    - **System Reliability:** Identified as a high-risk component in the "Issue-Specific Semi-Quantitative Risk Analysis for Emergency Overflow Spillway Operation" report due to its lack of redundant controls and mechanical defense in-depth components.
    - **Safety Implications:** Essential for preventing scenarios like reservoir overtopping and dam failure, which pose significant safety risks.

Current System Challenges

1. **Atlas Electrical Controller Issues:**
    - **Aging Technology:** Installed in the early 2000s; lacks current OEM support with essential parts no longer available from the original manufacturer, General Electric.
    - **Spare Unit Risks:** Currently, only one spare Atlas controller is available for all six units, which increases the risk of operational disruptions if the active unit is damaged by external factors like lightning strikes or overheating. Additionally, the spare controller is the same age as the original equipment and has not been used for several years, so its reliability cannot be fully guaranteed at this time.
    - **Integration and Maintenance Challenges:** The Atlas controller’s limited capability with the plant's Ovation system complicates troubleshooting, leading to longer downtime during failures. This system’s shortcomings are compounded by its inadequate production historian capabilities.
2. **Mechanical System Deterioration:**
    - **Operational Reliability:** Frequent mechanical failures have impacted the effectiveness of wicket gate operations, posing risks of "runaway" unit conditions under failure modes. The probability of a runaway unit condition under certain

modes of operation does exist but could be minimized by modern design features.

- **Component Wear:** Historical oil pump failures could cause binding of the distributing valve, making the operating mechanism stuck in its current position.

3. Outdated Component Concerns:

- **Reliability Threats from Aging Components:** The existing electrical system contains various original relays, timers, and instruments that are beyond their service life, posing risks to unit reliability.
- **System Obsolescence:** Continuous reliance on these outdated components without readily available replacements heightens the risk of unexpected failures.
- **OEM Support Discontinuation:** Original system components are obsolete, with sporadic support transitions impacting long-term maintenance and parts availability.

4. Conclusion

The Unit governor systems at the Ludington Pumped Storage Plant are crucial for ensuring safe and efficient plant operations. Currently, the system is compromised by outdated components and a lack of redundancy, highlighting a pressing need for a comprehensive upgrade. A critical spare component of this system (Atlas) has become completely obsolete, significantly increasing the risk to the station. Fortunately, the past 50 years have seen significant technological advancements that address many of the issues historically experienced with the LPS governors. These modern solutions not only enhance the system's reliability but also correct previous deficiencies, providing a valuable opportunity to significantly improve the system’s performance and safety. Upgrading these components is crucial to mitigate the high level of risk associated with the current governor system.

Alternative Solutions/Alternatives Considered

1. Do Nothing – Estimated cost of $19.8M per occurrence.

The "Do Nothing" alternative involves maintaining the current governor systems at the Ludington Pumped Storage Plant (LPS) without implementing the proposed upgrades. This option would forgo any modernization efforts and continue operations with the existing Atlas controllers and mechanical systems, which are significantly outdated and lack modern safety features.

Implications

1. **Reliability and Risk:**
    - **Failure Probability:** The current probability of a critical failure in this system is estimated at 20% within the next five years, with an annual increase of 5% thereafter. A critical failure is defined as an event that causes a forced outage lasting at least two weeks.
    - **Unit reliability:** A scenario in which our only spare Atlas controller failed if in use would result in one of the units being offline for 8 months.
2. **Increased Costs:**
    - **ROR and O&M Costs:** Continuing with the existing system will result in increased Repair, Operating, and Maintenance costs due to the aging components that are nearing or have reached the end of their service life.
    - **Component Replacement – cost of $4.4M (100% dollars):** As many parts are now obsolete, finding suitable replacements could be costly and potentially require custom solutions, further increasing expenses. If Atlas were to fail the plant only has 1 spare Atlas for all six units and no ability to obtain a new spare. The cost of replacement for one unit would be an estimated $4.4M. This considers all loadings and a 50% markup for emergency rush installation.
    - **Net Energy Value losses - $2.7:** An 8-month outage of a single unit at Ludington Pumped Storage Plant is estimated to result in a net energy value (NEV) loss of $2.7 million. This estimation is based on an annual NEV of $4 million per unit. The calculation assumes a worst-case scenario, as such an extended outage would result from an unplanned failure rather than scheduled maintenance.
    - **Potential Capacity losses - $12.7M:** If one unit is out of service for 8 months, the estimated potential capacity losses are $12.7 million. This is based on the following assumptions:
        1. Cost of New Entry (CONE): $127K/MW-year
        2. 75% of CONE: $95K/MW-year (used for calculation)
        3. With 178 average Zonal Resource Credits (ZRCs) for all Ludington units, the loss calculation is as follows:

4. Replacement for 3 out of 4 seasons (75% of the year): 178 ZRCs * 75% * $95K = $12.7M
5. 3.

This estimation assumes the need to replace capacity during a forced outage to avoid future accreditation impacts (no three-year penalty), valuing capacity at 75% of CONE.

- **Safety Concerns:** This option neglects one of the highest contributing systems to reservoir overtopping risks as identified in the “Issue-Specific Semi-Quantitative Risk Analysis for Emergency Overflow Spillway Operation” report. Continuing with the current system could significantly increase the risk of dam failure due to inadequate response capabilities during critical conditions.

3. **Technological Obsolescence:**
    - **Outdated Technology:** The current unit governor systems use technology surpassed in efficiency, reliability, and safety**.** Better technology exists today that can substantially decrease the risk of failure and improve operational control.

Conclusion

While initially cost saving, the "Do Nothing" option presents substantial long-term risks and costs, making it an unsustainable choice. The increasing likelihood of failures on obsolete critical components, combined with the outdated nature of the current systems and the availability of advanced technology, strongly argues against this alternative.

2. Controls replacement only– Internal loaded estimate of $4.0M (100% Dollars)

Option 2 focuses on the replacement of the electrical control systems for all six units at the Ludington Pumped Storage Plant. This option is limited to updating the control systems without addressing any of the mechanical components.

Implementation Details

- **Cost and Timing:** The project is estimated to cost $4.0M in capital expenditure. Implementations are planned during the plant's scheduled outages, which occur every three years and last for three weeks, thereby minimizing operational disruptions.
- **Equipment Lifespan:** The upgraded electrical control systems are expected to last 20-25 years, significantly improving the reliability of control operations.

Limitations

- **Exclusion of Essential Mechanical Components:** Option 2 focuses solely on updating the electrical controls and does not address the critical mechanical components necessary for the plant's operational integrity. The following key components identified

by internal subject matter experts as crucial for reliable operation remain unchanged and are not included in this upgrade:

- **Distribution Valve (Secondary Mechanical Rate):** Essential for controlling the flow and pressure within the system.
- **EHI (Electro-Hydraulic Interface):** Crucial for interfacing between electrical signals and hydraulic operations.
- **Retarding Valves for Wicket Gate Servomotors**: Important for controlling the speed and positioning of the wicket gates.
- **Drain Oil Piping for Governor Pressure Tank:** Necessary for maintaining proper oil pressure and flow.
- **Governor Oil Sump Sight Glass and Sump Foaming**: Critical for monitoring and maintaining oil levels and quality (first unit only).
- **Emergency Distributing Valve Bypass:** Provides a critical safety mechanism during system failures.
- **Hydraulic Piping and Tubing:** Integral for the seamless transfer of hydraulic fluids throughout the system.
- **Air Brake System:** Essential for the safe operation and maintenance of mechanical movements within the governor system.
- **Incomplete Solution:** While the control upgrades may enhance certain operational aspects, critical mechanical issues remain unmitigated, which can lead to increased system vulnerability.

Risk Assessment

- **Initial Failure Probability Reduction:** The likelihood of critical failures is projected to decrease to 3% within the first five years post-implementation.
- **Long-term Risk Increase:** The probability of failures is expected to increase by 2.5% annually after the initial period, due to the aging and unreplaced mechanical components.

Conclusion

While Option 2 offers a less expensive alternative with minimal disruption to plant operations, it provides an incomplete solution by neglecting essential mechanical components of the system. This option's scope is limited to control replacement, which does not address the mechanical vulnerabilities crucial for reliable system operation. The failure to replace key components identified by our subject matter experts results in this option not being viable for ensuring the long-term operational stability and safety of the plant.

3. Select Replacement – Internal estimate $17,719,930 (100% dollars).

Option 3 entails a selective upgrade of the control and mechanical systems at the Ludington Pumped Storage Plant, targeting components most critical for improving reliability and operational efficiency. This option integrates a new control scheme compatible with the upcoming Ovation system and replaces essential mechanical components that are nearing the end of their service life and have a history of damage or failure.

Implementation Details

- **Control System Upgrade:**
  - **Integration with Ovation System:** The new control system will be designed to pair seamlessly with the advanced Ovation system, enhancing the plant's operational capabilities through improved control and diagnostics.
  - **Electrical Components Replacement:** Critical electrical components and instruments will be updated to ensure ongoing spare parts availability and to maintain system reliability.
- **Mechanical System Upgrades:**
  - **Component Replacement:** Major mechanical components such as the distributing valve, pilot valve, unloader, and brake valve will be replaced due to their critical role in system operation and current end-of-life status.
  - **Retention of Key Components:** Servo motors, accumulators, significant portions of the power piping, and the existing cabinet structure will be retained, minimizing the scope and cost of physical changes.
- **Safety Enhancements:**
  - **Defense in Depth Improvements:** New safety features, including a distributing valve bypass, will be incorporated to enhance the system’s overall safety profile and operational resilience.
- **Cost and Schedule:**
  - **Estimated Cost:** The total capital expenditure for this option is estimated at $17,719,930 for all units.
  - **Implementation Schedule:** The replacement work will be strategically planned to coincide with scheduled outages to minimize disruption to plant operations.

Industry Benchmarking

- **Sector Best Practices:** Feedback from major hydroelectric OEMs (Original Equipment Manufacturer) and budgetary assessments indicate that this partial replacement strategy is commonly adopted by utilities with similar units. This approach aligns with industry best practices and meets reliability targets effectively.

Risk Assessment

- **Balanced Approach:** By selectively replacing and retaining components, this option strikes a balance between cost-efficiency and substantial system improvements. It addresses the most critical vulnerabilities without the need for a complete system overhaul.
- **Reliability and Spare Parts:** Updates to control and mechanical systems will significantly reduce the risk of failures and ensure easier maintenance through improved parts availability.
- **Reduced Initial Failure Probability:** Post-implementation, the probability of a critical failure is estimated to decrease to 1% within the first five years.

Conclusion

Option 3 presents a robust strategy for the governor system modernization at Ludington Pumped Storage Plant. It presents a comprehensive approach to upgrading critical components, ensuring compatibility with new technological standards, and adherence to industry best practices. This approach effectively addresses the plant's needs, proposing a solution that enhances long-term operational stability.

Recommended Alternative: Option 3 - $17,719,930 (100% dollars)

After thorough evaluation of all alternatives for modernizing the governor system at Ludington Pumped Storage Plant, Option 3 - Partial Replacement has been selected as the most viable and beneficial approach. This decision is grounded in a comprehensive analysis of the plant's needs, the potential risks associated with different strategies, and the overall goal of enhancing system reliability and safety while ensuring cost-effectiveness.

Rationale for Partial Replacement

1. **Balanced Approach to Modernization:**
    - **System Compatibility and Upgrades:** The partial replacement will integrate seamlessly with the new Ovation system, enhancing control and monitoring capabilities. This strategy allows for the retention of robust existing components such as servo motors and accumulators, while outdated and critical components like the distributing valve, pilot valve, unloader, and brake valve are replaced to address specific vulnerabilities.
    - **Reduction in Risks:** By replacing obsolete components and improving the system design, this option significantly decreases the likelihood of unit failure and the associated risk of dam failure. Additional safety measures and defense-in-depth features are incorporated to bolster system reliability during extreme conditions.

2. **Cost and Efficiency Considerations:**
    - **Cost-Effective Solution:** Compared to a complete replacement, this option is less costly and avoids unnecessary expenditure on replacing still-functional components. It provides a targeted, effective upgrade without the extensive capital outlays required for a full system overhaul.
    - **Minimized Operational Disruption:** The upgrades can be implemented during scheduled outages, thereby minimizing disruption to plant operations, and reducing the downtime typically associated with more extensive refurbishments.
3. **Addressing Obsolescence and Enhancing Reliability:**
    - **Spare Part Availability:** The upgrade ensures that all replaced components are supported with readily available spare parts, addressing one of the critical vulnerabilities of the current system.
    - **Addressing Legacy Issues:** The existing control system and mechanical components have demonstrated increasing failure rates. This trend is poised to worsen, as highlighted by the rise in failures over the past decade and the expected continuation of this trend. Modernizing these components directly addresses these reliability issues.
    - **Improved OEM Support:** Transitioning to newer systems with robust OEM support from GE/Nexus facilitates better maintenance and quicker responses to system issues, which enhances overall plant reliability.
4. **Enhancements in Monitoring and Troubleshooting:**
    - **Improved Diagnostic Capabilities:** The integration with advanced systems like Ovation enhances the plant's ability to perform condition monitoring and decreases troubleshooting time, directly reducing operational costs and system downtime.
    - **Updated Documentation:** Replacing old, often illegible electrical drawings with updated, accurate documentation will further enhance maintenance efficiency and system operability.

Option 3 - Partial Replacement stands out as the most strategic approach for updating the governor systems at Ludington Pumped Storage Plant. It balances the need for modernization with cost considerations, addresses the critical risks associated with the current system's obsolescence, and aligns with industry best practices for reliability and safety enhancements. By choosing this option, the plant will not only meet current operational demands but also establish a foundation for sustainable long-term performance and safety.

Budget Revision Justification

The initial estimate for the modernization of the governor systems at Ludington Pumped Storage Plant was set at $4.55 million (51% dollars). However, recent developments in the bidding process have necessitated a significant revision of the project budget. The current internal estimate has been adjusted to $9,890,751 (51% dollars), reflecting updated market conditions and actual bids received.

Reasons for Budget Increase

1. **Actual Bids Exceeding Initial Estimates:**

- The lowest cost bid received for the project was slightly under $13 million (100% dollars), significantly higher than the initially estimated $9.1 million. This discrepancy highlights a substantial underestimation in the original financial planning.
- The only other bid received was over $20 million, further indicating that the initial cost expectations were unrealistically low.

2. **Initial Budgeting Basis:**

- The original estimates were based on bids received four years ago. Since then, market conditions have changed, and costs for materials, labor, and technological components have increased, impacting the overall project cost.

Scope of work

The project aims to modernize the governor systems of all six units at Ludington Pumped Storage Plant (LPS). This comprehensive upgrade is designed to enhance operational reliability, safety, and compliance with current technological standards.

Components of Modernization

1. **Controller and Electrical System Upgrades:**
    - **Controller Replacement:** The current Atlas controllers will be replaced with state-of-the-art controllers featuring Human-Machine Interfaces (HMIs) for enhanced user interaction and monitoring.
    - **Auxiliary Electrical Equipment:** Introduction of new auxiliary electrical systems to support the upgraded controllers.
    - **PLC Enhancements:** Additional Programmable Logic Controller (PLC) functionalities will be incorporated to minimize failure modes and provide component redundancy.
2. **Mechanical System Redesign:**
    - **Hydraulic Control Devices:** Installation of new hydraulic controls tailored to address and rectify existing operational challenges.

- **Safety Features:** Implementation of advanced safety features like a distributing valve bypass to mitigate risks associated with unit control loss.

3. **System Compatibility and Integration:**
    - **Ovation System Compatibility:** Ensuring new systems are compatible with the future Ovation system to enhance trending and troubleshooting capabilities.
    - **Drawing Package:** A new, clear drawing package will be provided to replace outdated and illegible documentation, facilitating better maintenance and operational procedures.
4. **Implementation Schedule:**
    - **Staggered Installation:** The upgrade will be executed on two units per year, aligned with each unit's scheduled periodic outage to minimize operational disruption.

Compliance and Longevity

- **Codes and Standards:** All modernization efforts will adhere to applicable international and industry-specific standards.
- **Service Life Specifications:**
    - **Mechanical Components:** Specified for a minimum of 50 years of mechanical service life.
    - **Electrical Controls:** Specified for at least 20 years of service life, ensuring long-term reliability and efficiency**.**

Funding and Timing

- Funding that has been previously committed for this project: $440,225
- A Scheduled outage is required for this project.
- Desired implementation year: first year spend 2022 with installation planned for 2025-2028.
- System Engineer: Steven Morris

Conceptual Estimate

Year	Loaded Cost	Description
2022	**$ 96,011**	51% dollars. Engineering and planning
2023	**$ 128,504**	51% dollars. Engineering and planning
2024	**$777,250**	51% dollars. Engineering and planning. Procurement and preparation for installation
2025	**$1,431,751**	51% dollars. Final design and installation
2026	**$2,182,915**	51% dollars. Installation
2027	**$2,182,915**	51% dollars. Installation
2028	**$2,512,316**	51% dollars. Installation
2029	**$25,500**	51% dollars. Monitoring, Post Maintenance testing, Documentation and Closeout

Total Cost: 51% dollars - $9,037,164. 100% dollars – $17,719,930

Asset Strategy Approval Comments

The Asset Strategy team recommends approving Option 3 - Partial Replacement for the governor systems at Ludington Pumped Storage Plant due to critical concerns about part obsolescence and dam safety.

Key Points Supporting Approval

1. **Mitigation of Obsolescence and Reliability Issues:**
    - **End-of-Life Components:** Critical components have reached their service life and are obsolete, significantly impacting system reliability and necessitating their replacement to avoid Unit availability.
2. **Enhancement of System Redundancy and Reliability:**
    - **Redundancy Improvements:** The introduction of redundancies and defense in depth will provide a failsafe operational setup, crucial for maintaining operational integrity.

This investment **is** included in the current electric rate case.

Amount set for Bridge year: $345,000

Amount set for test period: $424,000

Intake gate controls are obsolete

Difficulty sourcing parts in the past, such as control power transformers

Rotary limit switch is difficult to adjust

Mag amp modules and master signal modules will not adjust to specified test values

Current difficulty sourcing a direct replacement for Unit 1's speed switch

A 2020 condition assessment by the OEM identified corrective actions

Rust / corrosion

Leaking gear box seals

Inadequate lighting (since replaced with LED)

Deteriorating holding brakes

Control panel deterioration and dew point condensation

Old hoist motor

Unit 6 drum and pinion gear damage

Investment Type	Generation	Planning Portfolio	Ludington
Facility	Ludington / Ludington		
Executive Summary	The LPS - Intake Gate and Gate House Mechanical Refurbishment project aims to address the obsolescence and deterioration of intake gate controls at the Ludington facility. Scope The project involves replacing instrumentation and controls on six intake gate hoists, including the main control panel, maintenance control station, gate position and cut-out coupling limit switches, gate tachometers and speed switches, control interlocks, holding brake and cut-out coupling solenoids. The goal is to maintain existing intake gate hoist control functionality, eliminate the need to bypass penstock prime interlock, update controls to state-of-the-industry standards for utility-grade hydropower applications, maintain output of critical operating parameters to the plant's DAS/DCS, maintain plant-based emergency lower initiation, and test functional controls fully, including emergency lower functions, in a way that minimizes consequences of failure during testing. Objectives Restore reliability to the intake gate emergency lower function Ensure safe and reliable normal intake gate control function Avoid tie to moving target outages Recommended Alternative The planner recommends refurbishing the intake gate and gate hoist. The 2025 authorized budget will be used to issue RFI to hoist vendors to gather information on current controls upgrade offerings, then rewrite the purchase specification and issue a new RFP for the revised scope of work. The controls upgrades and testing will be implemented from 2027 to 2029 during unit periodic outages, with a total cost of $1,167k 51% CE share each of those years. Model Assumptions: The project assumes a general scenario of a 7-month long forced outage with a 10% probability of occurrence over the next 5 years. The potential capacity losses in the event of a 7-month single unit forced shutdown have been calculated at $20,368,403. The calculations were made using a conservative calculator provided by the capacity forecast team, with a CONE value of $130,930.

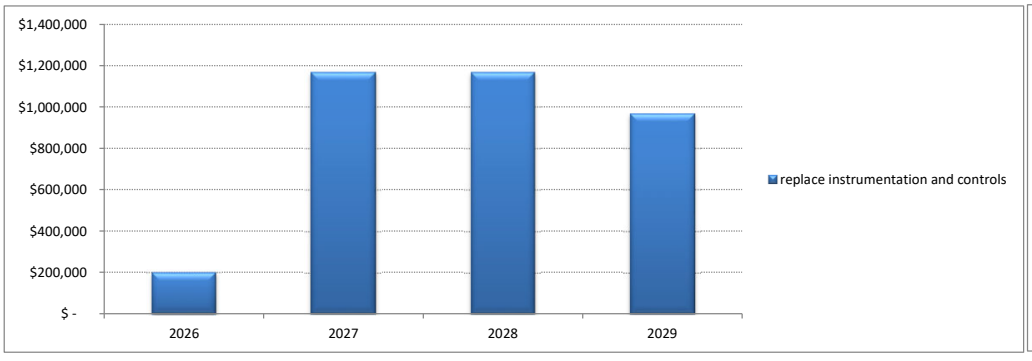
Concept Approval Internal Report

Investment Code	Report Start Year	Number of Years	Currency Scale
GEN001804	**2026**	**4**	**Literal**

Investment Name	Scenario
LPS - Intake Gate and Gate House Mechanical Refurbishment	**Draft**



Value Function	**Consumers Energy Value Function**

	Objectives	Mitigate forced shutdown risk Restore reliability to the intake gate emergency lower function Safe and reliable normal intake gate control function Avoid tie to moving target outages
	Planner Recommended Alternative	refurbish intake gate and gate hoist. Use 2025 authorized budget to issue RFI to hoist vendors to gather information on current controls upgrade offerings, then rewrite purchase specification and issue new RFP for revised scope of work $125k 51% CE share Implement controls upgrades and testing from 2027 to 2029 during unit periodic outages $1,167k 51% CE share each of those years, so no LTFP change in 2027 and 2028 while 2026 pushes to 2029
	Assumptions	a 7-month long forced outage scenario will be assumed if nothing is done and the control system fails to operate when called upon during an emergency. A 10% probability of occurrence over the next 5 years will be assumed for this case based on recent operational history. This equates to a little over 2% per year. 3% will be used due to software limitations. We experienced a Unit 1 overspeed in December. An emergency lower in that instance may have avoided the five months of outage and $1.6M (and rising) in cost that we're currently incurring. Overall a total risk of $15M-$50M will be assumed at a 3% chance of realizing. This includes both cost of repairs as well as capacity losses from a postulated 7-month single unit forced outage. Potential Capacity losses in the event of a 7-month single unit forced shutdown have been calculated at $20,368,403. The calculations were made using a conservative calculator provided by the capacity forecast team. Three-year impact on Capacity revenue is included in this number. The CONE value used for this model is $130,930. 75% of CONE was used for the calculations as customary.

Ludington Station Power Transformer Replacement

Date: 04/03/2025

Prepared by: Paul Ohep

Figure 1. Ludington pumped storage station power transformers.

Executive Summary

The Ludington Pumped Storage (LPS) facility, facing challenges with its aging Station Power Transformers (SPTs) that have been operational for over 50 years, requires a critical upgrade. These transformers are integral for stepping down voltage levels for efficient power distribution, and their current state poses significant operational and safety risks.

Selected Option: Replacement of SPTs 2 and 22 in 2026, SPTs 1 and 11 in 2028 and SPTs 3 and 33 in 2030.

Financial Implications: The total cost of the project is $9,411,764 (100% dollars), with Consumers Energy covering 51% ($4,800,000). This investment is deemed strategically sound, considering the long-term benefits and the need to mitigate risks associated with the current aging infrastructure.

Project Benefits:

- **Safety and Reliability:** Reducing the probability of transformer failures, which can cause operational disruptions and pose safety hazards.
- **Modernization:** Updating auxiliary components to current standards, enhancing functionality and compliance.
- **Strategic Outage Planning:** Replacement work scheduled during planned outages taking advantage of other planned work that will allow transformer replacements, minimizing operational impact, and avoiding additional capacity value losses.

Strategic Justification: This proactive and strategic replacement is crucial for ensuring continuous power generation at the LPS facility. The project addresses immediate safety and operational concerns.

Financial Summary

Funding Type:	Capital
Estimated Total Cost:	51% dollars - $4,800,000. 100% dollars – $9,411,764

Proposed Start Implementation Year and Duration

First year spend: 2025

Installation schedule:

2026: SPA2, SPA22

2028: SPA1, SPA11

2030: SPA3, SPA33

Problem Description

At the Ludington Pumped Storage (LPS) facility, the existing Station Power Transformers (SPTs) have been operational since the site's inception and are now presenting critical operational challenges. These SPTs, which include Transformers 1, 2, 3 (20kV/4160V) and Transformers 11, 22, 33 (4160V/480V), are responsible for stepping down 20kV to 4160V and 480V power systems to power in-house loads.

Current Status and Issues

- **Minimal Maintenance**: Due to the site's critical load demands, the SPTs have historically undergone minimal maintenance.
- **Aging Equipment**: The current transformers are not expected to last another decade in their current condition.
- **Inspection Findings**: Recent inspections by a reputable electrical contractor revealed that some transformers are in "marginal" condition, with STA2 specifically needing replacement as soon as practical.

Key Findings from 2021 STA2 Inspection Report

- **Overall Health**: Marginal
- **Electrical Evaluation**:
    - The transformer's electrical test results for the winding were acceptable for continued operation.
    - The “Doble Frank” evaluation system judged the CH (Core to High voltage), CL (Core to Low voltage), and CHL (Core to High and Low voltage) as “deteriorated” and “investigate” when compared to a 0.5% power factor maximum. These metrics relate to the insulation health of the transformer, with higher power factor values indicating deteriorated insulation.
    - The power factors have all increased since the previous 2019 tests, indicating a downward trend in the transformer's health.
    - HV bushings are new and tested well, but flagged as "investigate" due to differences in test data from the old type U bushings.
    - LV bushing tests were satisfactory.
    - The oil tested at 30.9kV for the D1816 1mm test, which is above the 23kV minimum acceptance, but the oil power factor has increased since 2019.

Electrical Evaluation Recommendations

- The overall power factor tests and oil power factor tests indicate a declining trend in the health of the insulation of this transformer.

- Further lab dissolved gas analysis (DGA) sampling of the transformer is recommended to further validate and perhaps quantify a declining trend in the health of the insulation of the transformer.
- Due to the criticality, age, and test results of this transformer, regular testing, evaluation of spare transformer availability, and future replacement plans should be considered.

Additional Considerations

- **Similar Transformers**: The inspection reports for STA1 showed better results, but these transformers are the same model and vintage as STA2, with similar failure mechanisms and operational history.
- **Replacement Timeline**: According to the 2021 inspection results conducted by an external vendor, Sub Metro, which identified adverse data trends, Consumer's Energy site engineering recommends that STA2 be replaced within five years to prevent operational issues and potential capacity losses.
- **Predicting Failure**: Transformer failure is difficult to predict, but the consensus is that the transformers should last a couple more years. Accurate trending would require many data points, which are currently unavailable.
- **Replacement Challenges**: The station transformers are of an unusual voltage/size/configuration, making replacements hard to find. The last estimated lead time for procurement was 24 months, expected to increase.
- **Obsolete Design**: The general design of the transformers and auxiliaries has been obsolete for years, and LPS lacks any spare 4160V or 480V SPTs onsite.
- **Operational Risks**: SPT failure could be violent, posing collateral damage risks to other equipment and a safety hazard to personnel.
- **Unreliable Transformers**: Despite their light loading over the years, the transformers are increasingly unreliable. Replacement components are challenging to acquire due to obsolescence, and there is a lack of confidence in their ability to operate reliably for another ten years. Lead time for a replacement could be up to 24 months.

Figure 2 below (next page) shows station transformers control circuit components, gauges/temperature trip devices and cooling fan controls/power poor material condition. These components have been the source of numerous plant DC bus grounds. Replacement components are difficult or impossible to obtain due to obsolescence.

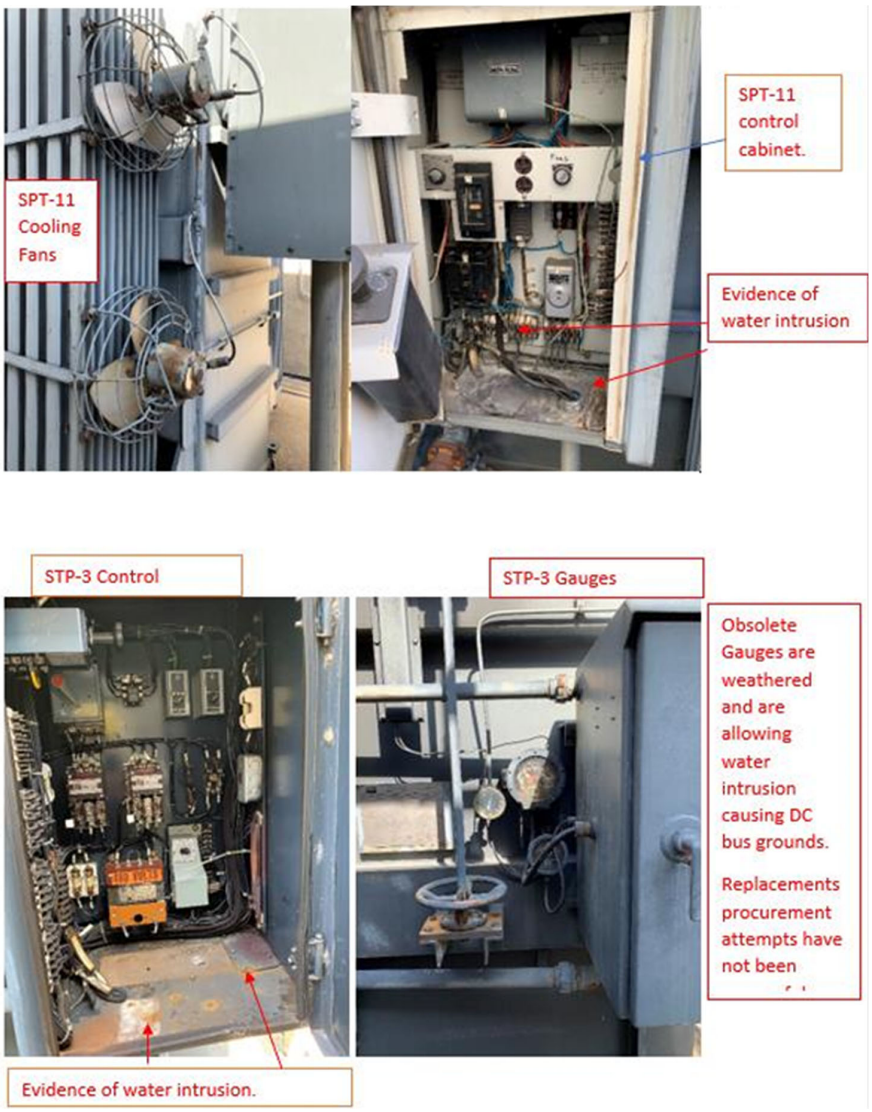

Figure 2. control circuit components

Alternative Solutions/Alternatives Considered

1. Do Nothing Top – cost $2.68M per failure

The "Do Nothing" approach involves continuing the operation of the Ludington Pumped Storage (LPS) facility without replacing the Station Power Transformers (SPTs). This option maintains the status quo, where the SPTs, which are original to the site and have been in service for over 50 years, continue to operate under the existing conditions.

Risks and Consequences:

1. **Increased Risk of SPT Failure:** As the transformers age, the risk of failure that would cause the unit to trip offline increases by 10% annually.
2. **Mandatory Time Between (MTB) Outages:** In the event of a transformer failure, an MTB outage of at least 7 days is required to isolate the SPTs. This results in operational disruptions and potential loss of generation capacity.
3. **Collateral Damage Costs:** A failure in one of the SPTs could be catastrophic, potentially causing collateral damage to other equipment at the site, which would incur additional repair costs.
4. **Replacement Costs Post-Failure:** If a transformer fails, the cost to replace it is estimated at $2 million, which is a significant expense in addition to the lost revenue and collateral damage costs.
5. **Loss of potential capacity revenue:** In the event of a transformer failure leading to an unplanned outage, Ludington Pumped Storage (LPS) could face significant losses in potential capacity revenue. Such an outage would necessitate taking two units offline for a week to isolate the malfunctioning transformer. The calculation of potential capacity value losses in this scenario includes:

    1. Zonal Resource Credits (ZRCs): The average ZRCs for two LPS units combines are 364.9. ZRCs represent the accredited capacity credits that a power generation unit contributes to the grid, used by grid operators like the Midcontinent Independent System Operator (MISO) for capacity planning and reliability.
    2. Cost of New Entry (CONE): The CONE value, set at $130,930, is a benchmark figure used by MISO to estimate the cost of bringing a new power plant online. It represents the per-day cost and is a critical component in calculating capacity market payments. For capacity calculations, 75% of the CONE value will be used ($98,198).
    3. Calculation of Lost Revenue: The potential loss in capacity value was determined using a calculator provided by the capacity forecast analysis department. This calculation is intentionally conservative (skewed towards less favorable outcomes) and does not fully incorporate all market dynamics relevant to the operation of the Ludington pumped storage station. The total

estimated potential capacity losses, due to having two units offline for 7 days, amount to $677,966.

I. Capacity lost revenue calculation basis:
The estimated capacity revenue loss of $677,966 was calculated using the standardized capacity calculator developed by the Capacity Forecast Analysis team. This calculator follows MISO guidelines and uses a two-step methodology based on outage duration and timing.

For this case, two Ludington units were offline for 7 days during the planning year. Because the outage lasted fewer than 31 days, the calculator applies a simplified loss estimation:

Lost Zonal Resource Credits (ZRCs) were calculated based on the outage duration as a fraction of the year and adjusted using the seasonal accredited capacity derate.

The lost ZRCs were then converted into dollar impact using the formula:
Lost ZRCs × 0.75 × CONE (Cost of New Entry)

The 0.75 factor is a standard adjustment applied when outages are ≤31 days or not in the planning year, representing a conservative revenue estimate.

The CONE value used was $130,990, with 75% of CONE applied per standard practice.

Pros to doing nothing:

- **Lower Immediate Expenditure:** This option involves the lowest upfront costs compared to undertaking a replacement project.
- **Avoidance of Immediate Project Execution:** Delays the need for immediate action and resource allocation for transformer replacement.

Cons to doing nothing:

- **Unplanned Outages and Associated Costs:** The facility must be prepared for unplanned outages with a minimum duration of 7 days to isolate a failed transformer, leading to significant revenue loss, potential capacity value and operational disruptions.
- **Increased Operational and Maintenance Challenges:** The facility will likely face more frequent failures and operational issues as the transformers continue to age and deteriorate.

- **Inevitable Lifecycle Management and Replacement:** The replacement of these transformers will eventually become necessary and delaying this can lead to more complex and costly interventions.
- **Safety Hazards:** A failure of an SPT could be violent, posing risks to other equipment and, more critically, to personnel safety.

2. Replace all 6 Station Power Transformers over 5 years – Internal estimate of $4,800,000 (51% Dollars)

Project Overview: This option involves the complete replacement of the existing Station Power Transformers (SPTs) at Ludington Pumped Storage (LPS). The project focuses on addressing the issues due to the aging transformers, which are over 50 years old and increasingly prone to failure.

Key Benefits and Implementation Strategy:

1. **Increased Equipment Lifespan:** Operating at the correct voltage will significantly extend the lifespan of the site equipment.
2. **Life Expectancy Alignment with Site's Operational Period:** The new transformers will have a life expectancy that matches the site's anticipated operational lifespan, ensuring consistent and reliable support.
3. **Routine Maintenance Without Risk:** The updated SPTs will allow for routine maintenance without the risk of equipment damage, crucial for preventing unexpected failures.
4. **Reduced Failure Probability:** Replacing the aging transformers will significantly lower the likelihood of unexpected failures, enhancing overall reliability.
5. **Mitigation of Spare Transformer Risks:** This project addresses the current risk associated with the lack of spare SPTs at LPS.
6. **Restored Tap-Changing Capability:** The new transformers will enable tap changing, essential for voltage regulation, which is currently hindered due to the aging SPTs.

Strategic Outage Planning:

- The replacement of all six transformers will be executed during planned outages over a period of 3 years. This phased approach ensures that there will not be additional capacity value losses incurred due to the project.

Cost Breakdown:

- The total cost for this replacement is $7,450,980, with CEC covering 51% of this amount, equating to $3,800,000. This investment includes the procurement and installation of new transformers and associated project management costs.

3. Replace/Repair Specific Components of STP– internal estimate of $2,151,855 (100% dollars), $1,097,446 (51% dollars)

Option 3 involves replacing or repairing specific components of the Station Power Transformers (STPs) at the Ludington Pumped Storage (LPS) facility. This approach focuses on addressing the most critical components currently failing or at risk of failure.

Key Aspects of the Project:

1. **Implementation in Phases:** The replacement or repair work will be carried out in three separate planned outages, each estimated to last 7 days. The total downtime for all outages is factored into the cost calculation.
2. **Cost Calculation:** The potential capacity value loss for each 7-day, 2-unit outage is calculated at $667,285, similar to Option 1. With three outages needed for this option, this totals $2,001,855. Additionally, $150,000 is estimated for parts and labor, bringing the total project cost to an estimated $2,151,855.
3. **Limited Scope:** This option focuses on the replacement or repair of only certain components of the STPs, not a complete overhaul or replacement of the transformers.

Pros:

- **Lower Equipment Cost:** The cost for parts and labor in this option is lower than the complete replacement of the STPs as proposed in Option 2.
- **Targeted Repairs:** Repairs are focused on the most critical components, potentially extending the operational life of these parts.

Cons:

- **Difficulty in Sourcing Components:** Replacement components are difficult, if not impossible, to find due to the obsolescence of the transformers.
- **Long Lead Times:** Procuring components that are available may have long lead times.
- **Limited Scope of Repairs:** Internal components and windings would not be repaired or replaced, which does not prolong the overall life of the transformer windings.
- **Persistent Low Voltage Issue:** Voltage at the site would remain low, continuing to affect equipment lifespan.
- **Ongoing Operational and Maintenance Challenges:** Even with repairs, operational and maintenance issues are likely to arise due to more failures.
- **Inevitable Lifecycle Management and Replacement:** Complete lifecycle management and eventual replacement of the STPs will still be required in the near future.

- **Safety Hazards:** The potential for violent failure of an STP continues, posing risks to other equipment and personnel safety.
- **Multiple Outages Required:** Several outages, each with an uncertain duration, will be required to perform the necessary work.

Recommended Alternative: Option 2, Replace Station Power Transformers – Internal estimate of $4,800,000 (51% Dollars)

Primary Advantages and Project Objectives:

1. **Voltage Stabilization:** Correcting the existing voltage droop, Option 2 ensures the Ludington Pumped Storage (LPS) operates at optimal voltage levels, crucial for efficient power generation.
2. **Restored Tap-Changing Capability:** The new transformers will enable tap changing, essential for voltage regulation, which is currently hindered due to the aging SPTs.
3. **Life Expectancy Alignment:** The transformers will match the LPS site's operational period, ensuring reliable power supply for the long term.
4. **Preventative Maintenance Enhancement:** The replacement facilitates preventative maintenance without risking significant damage, enhancing overall facility reliability and safety.
5. **Updated Auxiliaries:** Incorporating modern standards, the auxiliary components of the new transformers ensure improved functionality and compliance.
6. **Minimized Operational Impact:** By scheduling replacements during planned outages, operational disruptions and associated revenue losses are minimized, making it the most efficient option in terms of outage duration.
7. **Safety and Reliability:** This proactive replacement mitigates risks of violent failures, which could cause collateral damage and pose safety hazards. Replacing over 50-year-old critical electrical equipment preemptively avoids random failures and addresses the lack of spare transformers on site.

Option 2 is a comprehensive solution that enhances operational efficiency, safety, and future readiness of the Ludington Pumped Storage facility. This strategic investment in modern, efficient transformers significantly reduces unforeseen failure risks, aligning the facility with current safety and performance standards.

Scope of Work

Procure and replace all 6 SPTs with new to suit size and configuration in current LPS footprint:

1. Provide specification for RFQs and acquire quotes for replacement units 2 years in advance of expected outages of execution.
2. Re-align with asset management and stakeholders for funding and schedule requirements and authorization to proceed.
3. Award contracts, begin planning and procurement of replacement units, verify outages for installation are adequate.
4. Install replacement units during outages of opportunity once delivered.

Funding and Timing

- Funding that has been previously committed for this project: $0
- A Scheduled outage is required for this project.
- System Engineer: Anthony C. Szostak Jr

Conceptual Estimate

Year	Loaded Cost	Description
2025	$150,000	51% dollars. Design work
2026	$1,200,000	51% dollars. First round of installs
2027	$1,000,000	51% dollars. Second round of installs
2028	$1,200,000	51% dollars. Second round of installs
2029	$200,000	51% dollars. Design work
2030	$1,000,000	51% dollars. Third round of installs
2031	$50,000	51% dollars. Closeout

Total Cost: 51% dollars - $4,800,000. 100% dollars – $9,411,764

Asset Strategy Approval Comments

The Asset Strategy Group approves Option 2 for its cost-effectiveness and alignment with our budgetary efficiency goals. This investment in replacing the Station Power Transformers at Ludington Pumped Storage ensures operational reliability and safety while optimizing long-term financial outlay. Executing the replacement during planned outages minimizes disruptions and associated costs, demonstrating fiscal responsibility. OBJ

2025 Change Log Summary broke/fix Emergent Issues

Description	Cost (000's)	Details	Site
Karn ICS Additional Costs	$ 3,200	Estimated additional spending needed for Karn, POs written broke/fix GSU failure	Karn
Karn Fire & Transformer Move - Emergent Changelog	$ 2,000	HLI to Transport (1) Transformer by rail from West Olive, MI to Essexville, MI. -$1.2M	Karn
Covert HEPS & FAC - Emergent Changelog	$ 1,182	The team has evaluated whether these are “must do” vs potential deferral repairs. The plan includes the must do repairs. This project needs immediate approval to mitigate outage extensions.	CGS
Emergent - LPS - Unit 1 outage	$ 561	Emergent - Est. repair costs for the LPS Unit#1 Forced Outage due to a Runaway event on 12/4/24.	LPS
Gen Ops - CGS HEPS/FAC Emergent Request #2	$ 535	This is a true up to the original request for Covert HEPS discovery/repairs and since this is a significant increase we would like BUG and VP approval to proceed. We are building an offsetting strategy of downlevers that we will bring to the April change log to offset these requests. This request is for $535k of additional O&M to finish the repairs.	CGS
JGS MM Base Outage	$ 325	emergent repair to fire protection header- safety issue.	JGS
Gen Ops- Karn GSU Fire	$ 300	Initial ask to fund ICS at Karn for O&M	Karn
Covert - 2A Circ Pump Emergent	$ 285	Emergent approval via email on 10/7/2025 - broke fix	
JGS - Cooling Tower Repairs	$ 271	This is 1st & 2nd quarter immediate issues identified during the ICT level 2 inspections in the fall 2024 outage. Materials is being purchased 4th quarter 2024 and fall outage work scope will be done thru levers/flex or change log processes	JGS
EMERGENT - Covert Unit 1 Steam Turbine Valve Repair	$ 250	A recent inspection at Covert identified a crack on a high-pressure control valve bushing. These can become a very serious or dangerous issue and definitely take the unit offline when it fails. We need to address this issue immediately at our earliest outage of opportunity which is this fall to avoid safety and forced outage issues.	CGS
Emergent - Foote Downstream Concrete Repair	$ 205	Emergent - The hydro team requires $205k of O&M to finish this work. In our reviews we found out this project has been progressing and these are actual costs. We explored multiple options including stoppage of work. The decision to proceed now will save the customer approx. $30k on demob/mob of the crane. The majority of the work is completed.	Hydro
Gen Ops-Karn 4 Burner Oil Pump Leak PT-11178	$ 180	Broke/fix	Karn
Karn 4 FD Missing	$ 175	Structural issues inside the duct that need to be repaired	
PP-10219 Covert Fall Outage	$ 170	Additional funding needed to address issues at the Covert Generating Station during the fall outage.	CGS
JGS HRSG 7 Perforated Plate Distribution Wall failed	$ 150	Broke/fix in fall outage	JGS
JGS Duct Burner Isolation Valves	$ 140	Funding to replace the duct burner isolation valves on the HRSGs during the Fall outage – ahead of the originally planned Spring 2026 execution. We are continuing to experience valve failures in the field resulting in significant losses in power production. Our recent GVTC testing had poor results which will have significant impact to our 2026 capabilities. We are requesting $140k of O&M (cost plus expediting) to purchase replacements for all the failed isolation valves along with remaining carbon steel valves that are at risk of failing	JGS
Ludington Fish Barrier Net-Installation, Cleaning, Repairs & Removal	$ 128	Part of it is HDR, looks like their costs are about $10k more per month with their new contract. Part of it is UCC being more attentive about staffing this project. UCC's contract ends November 30, no new contract yet for December's rates	LPS
ZGS HRSG 2A & 2B Heat Trace Repair	$ 120	NERC required winterization	
Mio Spillway hollow chamber leakage sealing	$ 110	Leakage has been known, 2024 dive inspection found source. Need to repair to prevent sand ballast washout from the hollow chamber - dam stability	Hydro
Karn Forced Outage	$ 110	Broke/fix - Request of funding. Site does not currently have funding for forced outages	Karn
Gen Ops- Ausable River Queen Clean up	$ 100	Cleanup costs related to the Ausable River Queen incident. USEPA holding us accountable on some of the invoices. Plan is to recoup money from owners but unsure of timeline and plan.	Hydro
Karn 3&4 Louver Repairs	$ 100	This request only covers the scaffold costs. Anticipate utilizing plant resources to complete the work. There are approximately 10 to 12 louvers per unit that are inoperable, some stuck open allowing cold air to get into the plant during the winter. This caused freezing issues last winter affecting unit availability and even forced a must run condition when not necessarily economic for our customers. These issues occurred despite plant heating in service. Significant scaffolding over open areas (not accessible with lifts or JLGs) is required.	Karn
Karn Road Repairs	$ 100	Approved emergent via email on 11/6 failed roadway from previous water main leak	
Covert - Ammonia Fan Rebuilds	$ 93	moving 2025 funds to O&M for fan rebuild of the old design.	CGS
Covert U2 EE-OO Expansion Joint	$ 85	Approved emergent via email on 11/7	
Croton Unit 1 Generator	$ 80	There is a broken bus bar between the collector ring and the rotor poles on the Croton Unit 1 Generator.	Hydro
JGS - 480V WavePro Breaker Replacements	$ 75	Work was delayed in 2024 and a portion of the initial funding was utilized to address cubicle modifications due to an identified arc flash risk. These requested funds are to complete the rebuild and installation of the remaining half (quantity: 17) of the 480V breakers.	JGS
ZGS Outage Base	$ 70	HRSG Leaking penetrations seals plus insulation	
CGS - 1. Cable Vault Tray Supports – Failed	$ 68	This has been entered as a threat to generation (cable tray failure could compromise conductors and result in unit trip) – seeking planning and funding in 2025	CGS
CGS HRSG U3 Seals and Insulation replacement request	$ 64	Dome of the expansion joints installed last fall have failed. Worked with IAFD company to share cost of replacement. This is for seals and insulation.	
NEW - Covert Circ Pump Vibration Analysis	$ 62	The analysis being performed is highly technical and required to determine the root cause of our historical vibration issues with the pumps at Covert.	CGS
Karn B Aux Boiler FD Fan Shaft/Bearing Repair	$ 60	Karn B Aux Boiler FD Fan Shaft/Bearing Repair. Emergent Broke/Fix work.	Karn
LPS Unit 1 South Trash Rack Repairs	$ 60	Funding, time, and resources for this trash rack repair were used to offset the emergent repair of the Unit 3 south trash rack. Having repaired the Unit 1 south and Unit 3 south trash rack in 2024, we have a better idea of the level of effort needed to effect these repairs.	LPS
Hardy spill tube aeration flow meters and lighting	$ 55	•Modify the lighting circuit that lights the caverns by spill tubes 2 &3 to keep it out of the water running down the wall that has faulted that circuit. This is more a safety issue, there is no light down there but your flashlight when trying to complete maintenance or daily operation duties in those areas.	Hydro
LPS - Unit 6 shaft seal failure	$ 51	Not part of corrective action lawsuit	
Mio Spillway Hollow Chamber repair	$ 50	The divers discovered additional work needed. If work is completed now it would save remobilizing the contractor. Risk of not doing the work is loss of fill(washout) and destabilizing the powerhouse/spillway.	Hydro
JGS - LM Filter House Drift Eliminator Repl and Cooling Coil Cleaning	$ 50	The existing drift eliminators in the LM6000 filter houses are the original ones and are brittle and falling apart. Recent cooling coil performance testing by EPTS identified an average cooling coil efficiency loss of 15.9% from expected which is a reduction of total plant output of 2.85 MW under summer GVTC conditions.	JGS
Covert - auxiliary boiler leak repair	$ 46	EMERGENT approved email 8/11/2025	CGS
LPS IPB Inspection and Maintenance	$ 46	The IPB on MTB1 needs to be cleaned. This was discovered from the MTB1 inspection.	LPS
PP-10218 Covert U 3 HP Steam Leak Repair	$ 45	True-up of project with funds from the NERC Relay/DC Testing Compliance & Capacity Factor Projects.	CGS
LPS environmental	$ 43	Environmental allocation came in higher than planned in 2025	LPS
LPS - Generator Air Cooler Cleaning (6 Coolers)	$ 43	Generator Air cooler cleaning for coolers that were recently replaced	
Karn 3 & 4 - FW Heater safety relief testing & setting	$ 40	Components need testing; not suspected to have been inspected before	Karn
Ludington Fish Barrier Net-Installation, Cleaning, Repairs & Removal	$ 36	Run rate for Barrier net install was higher than planned	LPS
B-PH-00168 LPS Unit 3 South Trash Rack Dive and Repair	$ 36	Based on an inspection of the LPS Unit 3 south trash rack on 8/29, additional funding is needed to perform emergent repairs and a dive to remove debris from the sill slot during the Unit 3 pumping outage this fall.	LPS
LPS Unit #6 Intake Gate Drum Alignment	$ 28	The U6 intake gate drum alignment work is based on the system condition assessment by Stantec and visual inspections completed by CE team for the drum gear and drive. It was originally being considered under the Capital project for the Intake Gate Refurbish project, but this mechanical scope is repair only and alignment and so we are completing the work before we start the project.	
LPS - Observation Well Inspection and/or cleaning	$ 23	Elevated levels in the Obervation wells, Video Inspection needed and potential for a cleaning	
Covert - Site Diesel Generators– air inlet louver drive motors failed for both engines	$ 20	Louvers are supposed to open automatically upon engine start to ensure sufficient air for the engine and turbo chargers	CGS
Gen Ops - LPS intake gate slot bubbler orifices	$ 13	The intake gate slot bubbler orifices need to be replaced.	LPS
Gen Ops - LPS - Unit 2 Penstock Intake Repair	$ 10	Error in calculation going from 100% to 51% in previous changelog, did not request enough funding.	LPS
2025 TOTALS =	$ 12,049
